Y. Hoshino
(Kanagawa University, Japan)

VCI2016, 14th – 19th February 2016

Motivation

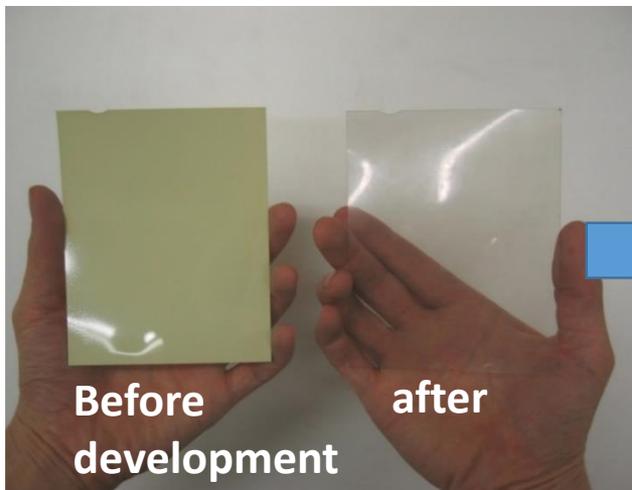

- Dark matter has yet to be observed experimentally
 - The DAMA/LIBRA claims the direct detection of WIMP by observing annual modulation signature
 - some other experiments found no signal
- Directional measurement can solve the problem
 - use signal's forward-backward asymmetry
 - different with annual modulation
 - need to detect a recoil nucleus as a track

Requirements for a detector

- Detector needs mass scalability
 - expected event rate: $< 0.01 \text{ kg}^{-1} \text{ day}^{-1}$
 - detector mass requires $O(10 - 100) \text{ kg}$
- Solid-type tracking detector has the mass scalability
 - recoil energy is expected to be $O(10) \text{ keV}$
 - track length will be $O(0.1) \mu\text{m}$
 - need nanometric position resolution
- Nuclear emulsion is one of the candidates

Nuclear emulsion

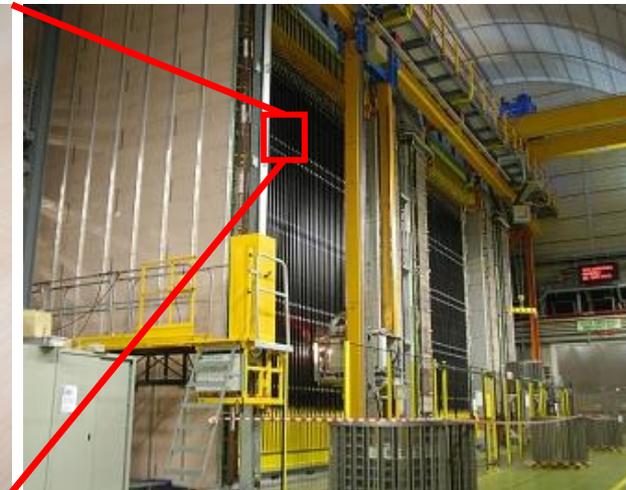

- Photographic film with sensitivity to a charged particle
 - position resolution: around $1\ \mu\text{m}$
 - mass scalability: up to tons scale
 - no time resolution

Nuclear emulsion films
for the OPERA experiment

Emulsion Cloud Chamber (sandwich of
57 emulsion films and 56 lead plates)

The OPERA detector
(Use 30 tons emulsion)

Detection principle

A silver bromide crystal is an extremely small sensor

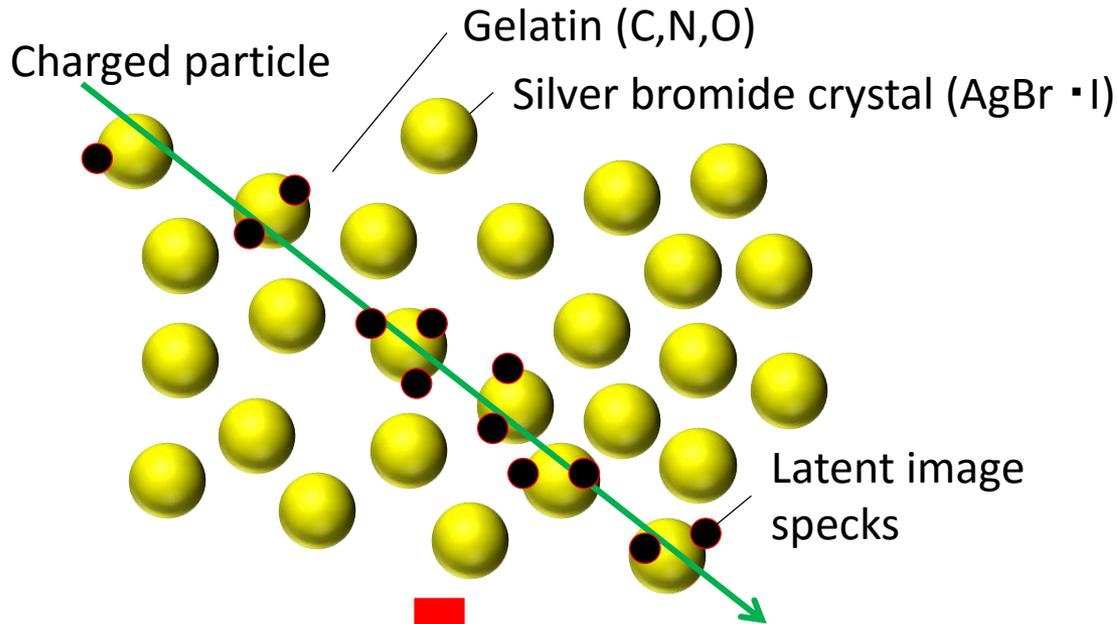

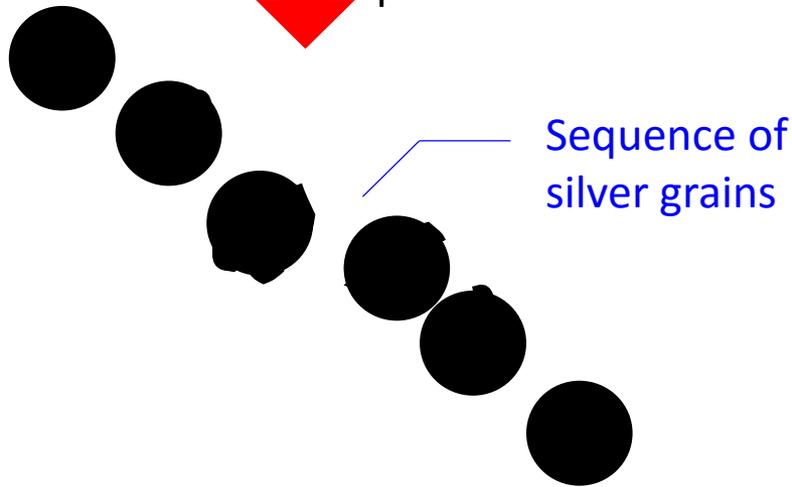

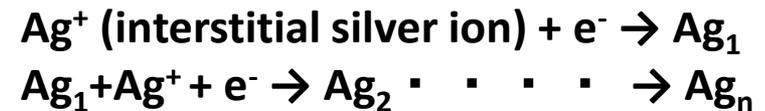

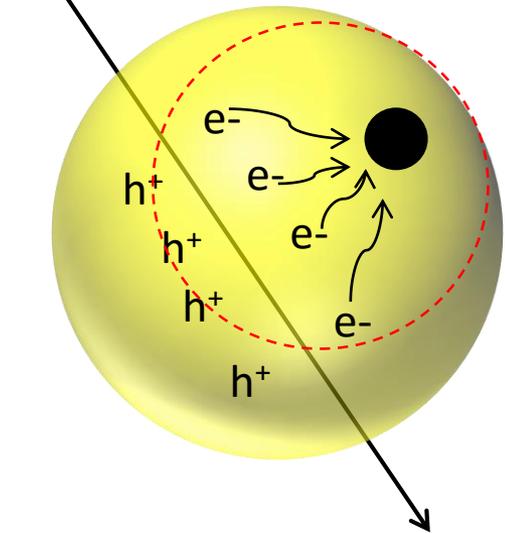

Photo-development

AgBr is semi-conductor with 2.6 eV bandgap

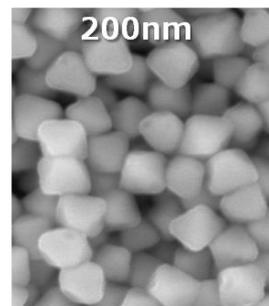

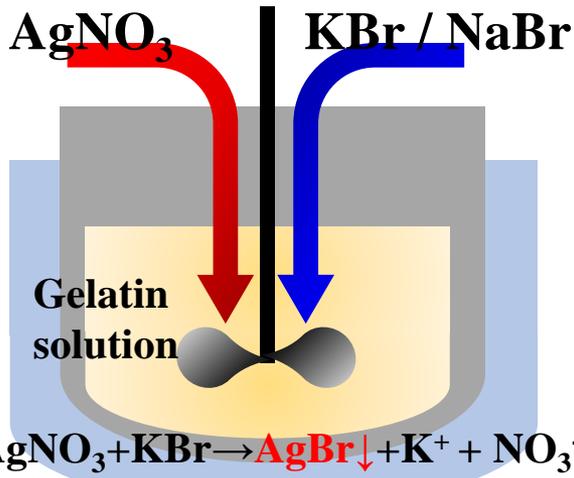

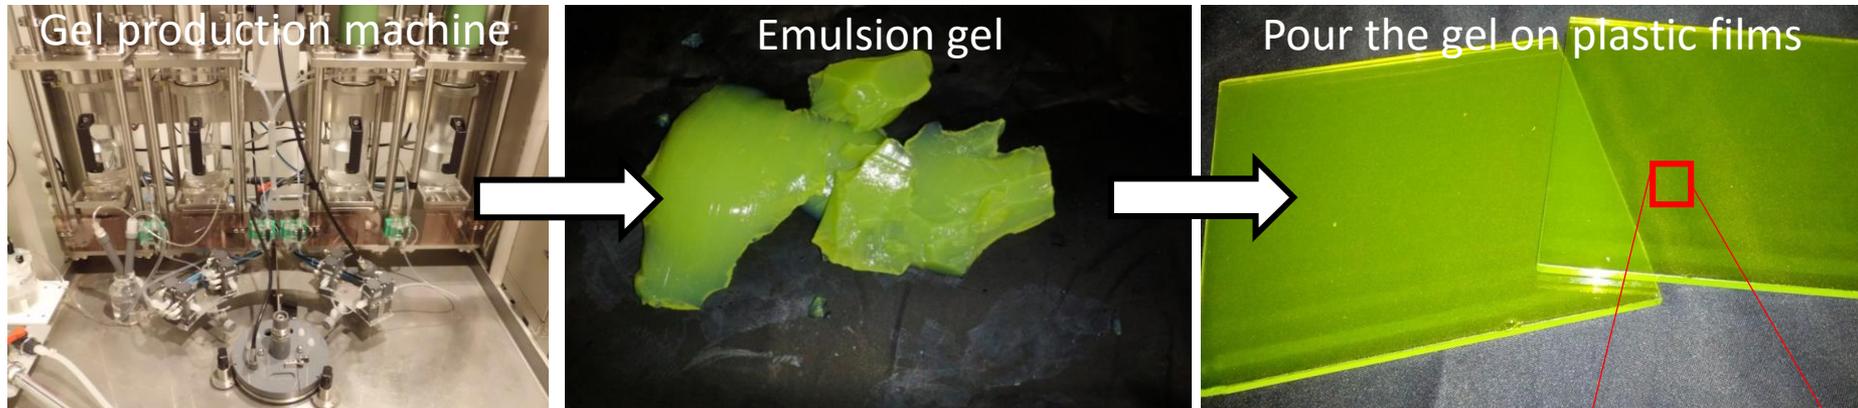

Grow the "latent image specks" Ag_n ($n > 4$) in photo-development by a catalytic effect

Visualize a track as a sequence of silver grains

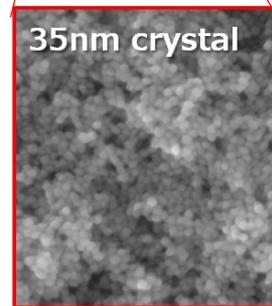

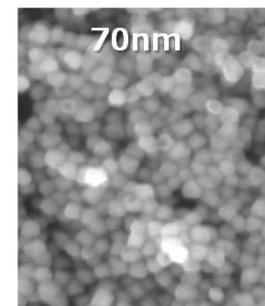

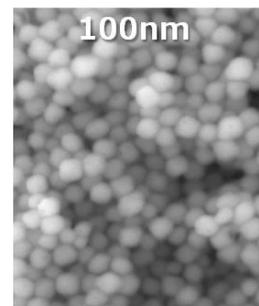

Fine-grained nuclear emulsion

- Fine-grained emulsion can detect an extremely short track
- Nagoya University introduced the emulsion production machine

T. Asada *et al.*, Journal of Physics: Conference Series 469 (2013) 012010

Usual emulsion

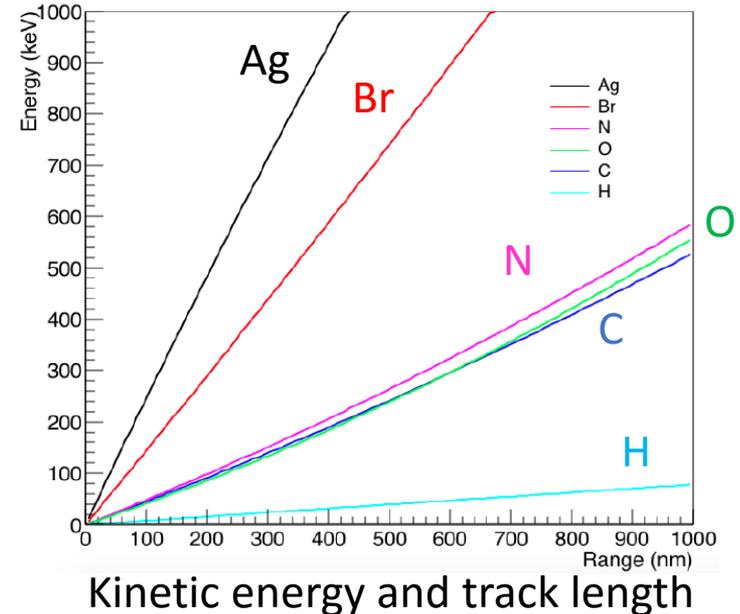

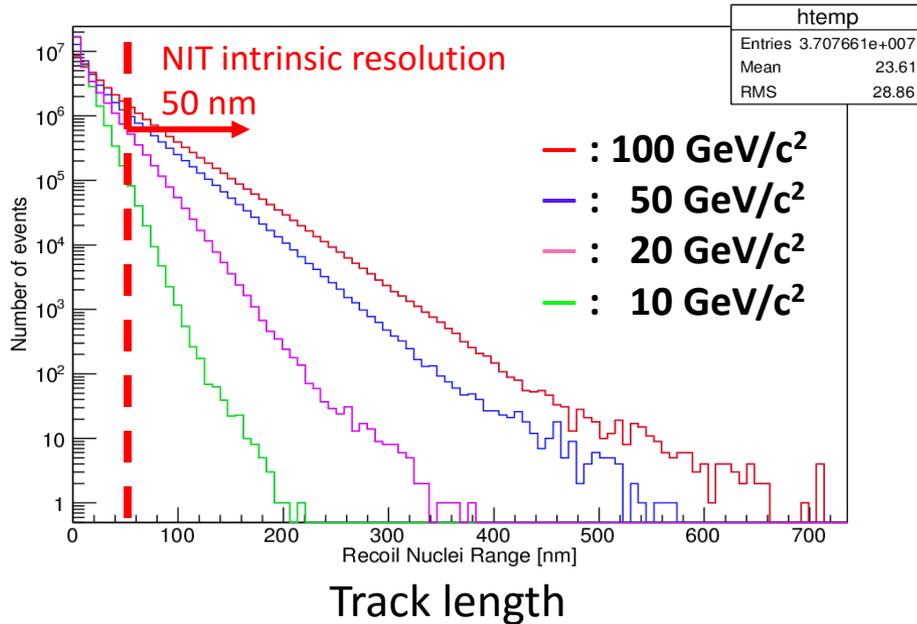

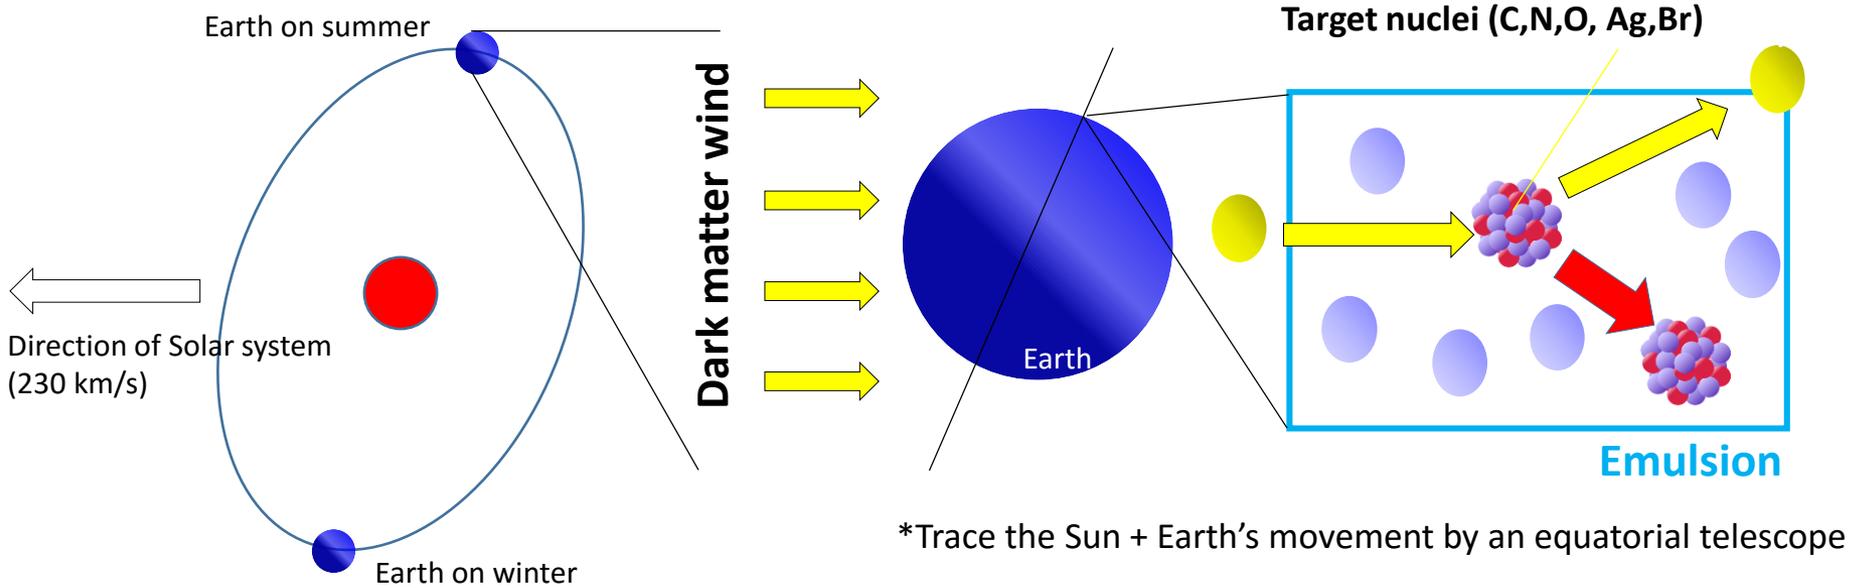

For dark matter

Usual emulsion: 2.4 crystals/ μm

For DM ("Nano Imaging Tracker: NIT"): 11 crystals/ μm

Directional Dark Matter Search with Nuclear Emulsion

Performance check

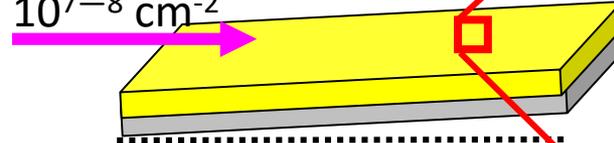

- Demonstrated WIMP signal detection by using low velocity ions were supplied by an ion implant system
- The detection sensitivities to C^+ , Kr^+ are consistent with 100% at room temperature

M. Natsume *et al.*, Nucl Inst. Meth. A. 575 (2007)439

Ion direction

10^7-8 cm^{-2}

Emulsion film

(tilted 10°)

C^+ direction

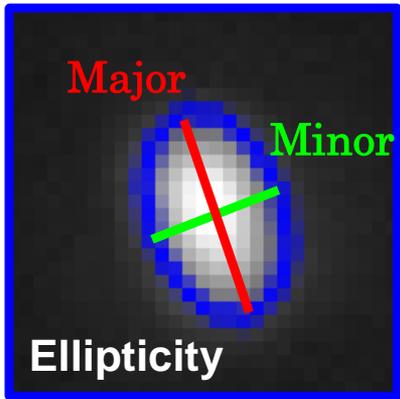

3 μm

Epi-illuminated microscopic view of
80 keV C^+ (track length $\sim 240 \text{ nm}$)

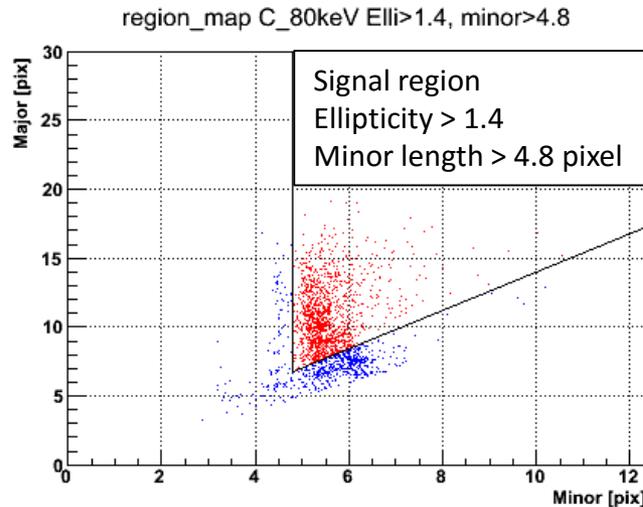

Signal selection and track reconstruction

- Extract signal candidates by using shape recognition based on ellipse fitting
- Observed anisotropy of low speed ions
 - consistent with beam incident direction

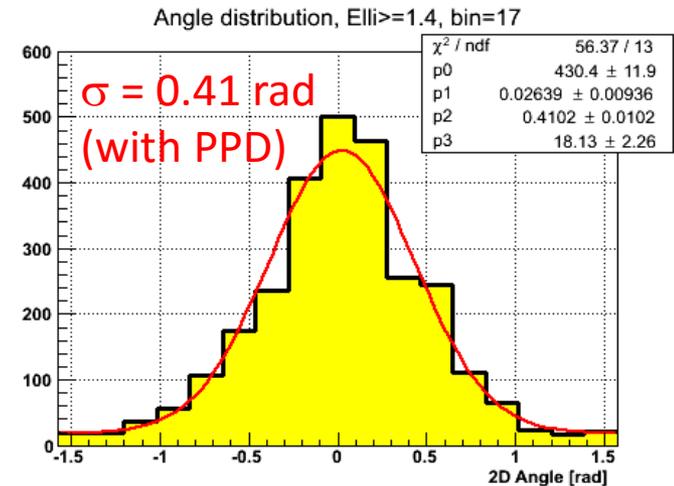

M. Kimura and T. Naka., Nucl. Inst. Meth. A. 680 (2012) 12-17

Extracted parameters by optical analysis

Major-minor distribution of 80 keV C⁺ ions in NIT

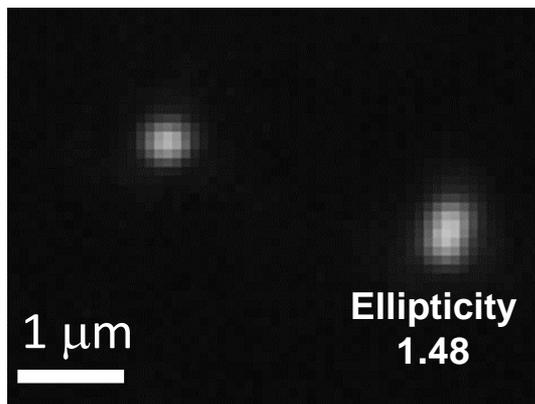

Angular distribution for the events in the signal region

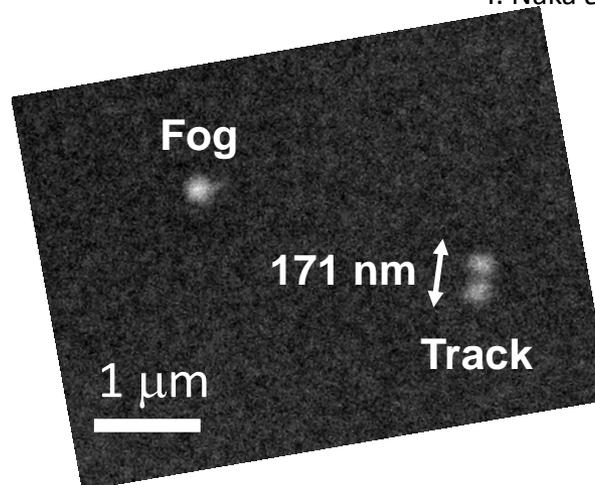

Signal confirmation

- X-ray microscope confirms the candidates
 - resolve the candidates into its components
 - signal is detected as a line of two or more grains
 - a single grain does not form a track (“fog”)

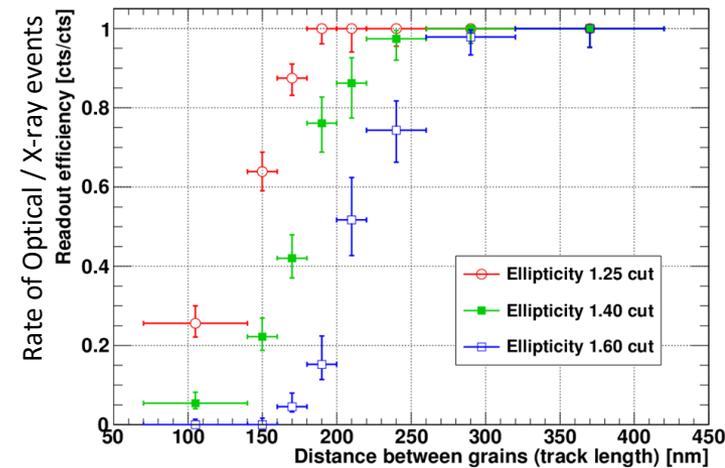

T. Naka *et al.*, Review of Scientific Instruments 86, 073701 (2015)

Optical image for Kr⁺ ions

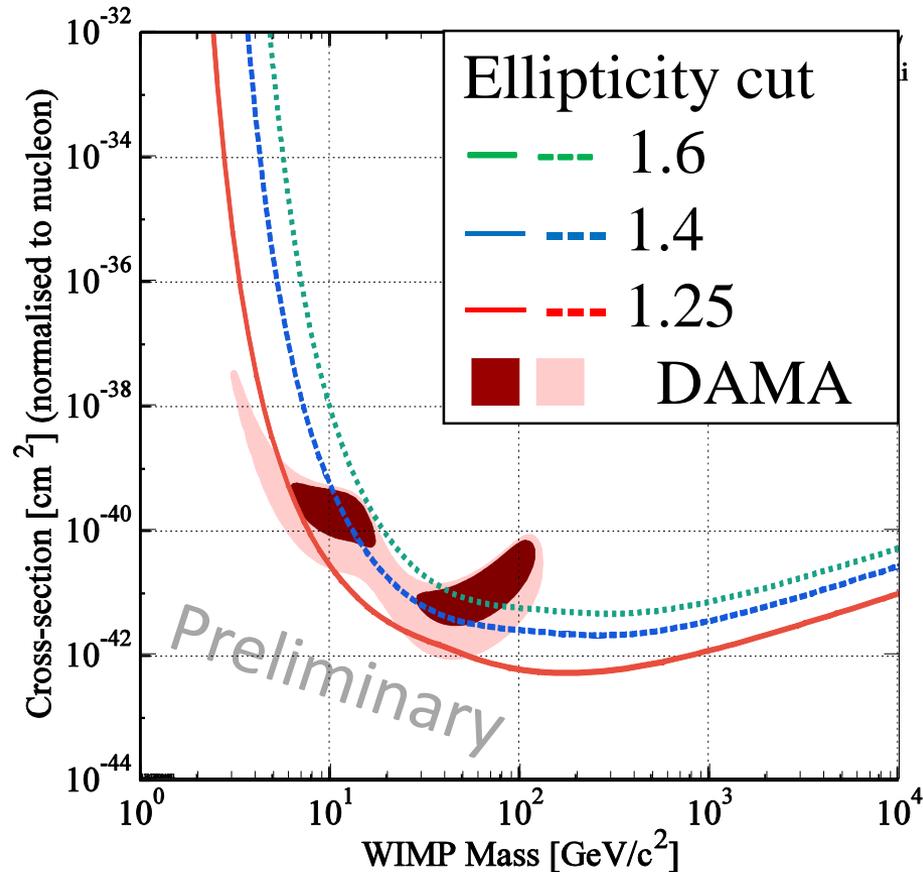

X-ray microscopic image
(using Spring-8, Japan)

Optical readout efficiency
as function of track length

Ideal sensitivity

- Need O(10) kg detector to investigate the DAMA region

Cross Section Limit (Zero background, 25 kg·year, 90% C.L.)

Background sources

- External components

- neutron due to cosmic rays

- radiation from radioactivity in bedrock

→ Underground Shield

- Internal

- dusts in gelatin binder → Gelatin filtration

- radioactivity in emulsion

- U, Th series

→ Gelatin purification

- ^{40}K

→ Replace KBr with NaBr

- ^{14}C

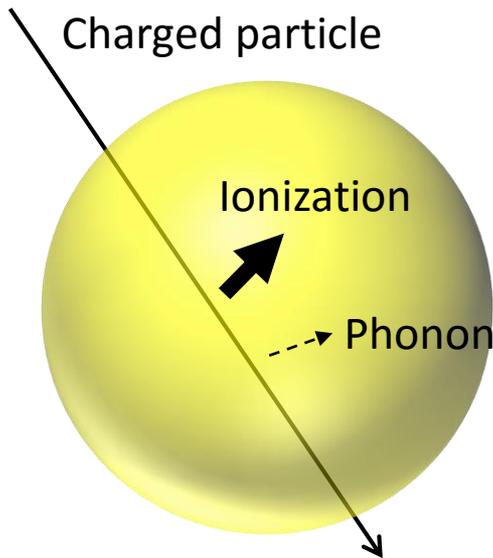

^{14}C in gelatin: $2 \times 10^6 \text{ kg}^{-1}\text{day}^{-1}$ (by AMS measurement)

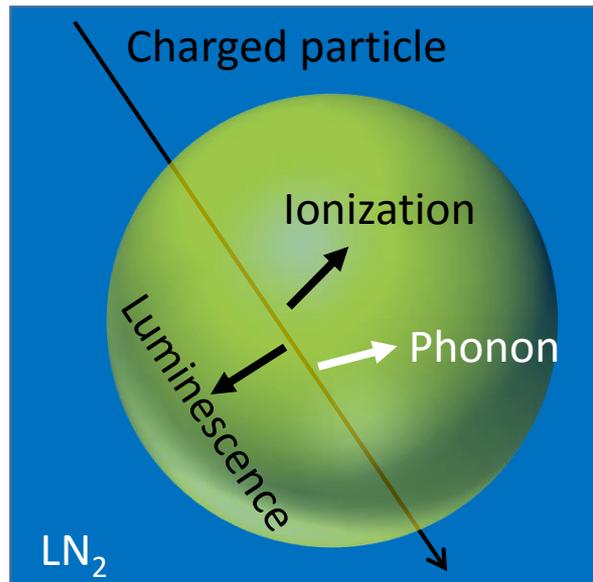

- (1) Use low activity polymer (PVA: $< 3 \times 10^{-3} \text{ kg}^{-1}\text{day}^{-1}$)
(2) Remove electron tracks by cryogenic approach

Concept of background rejection

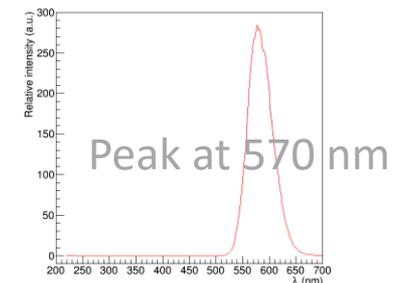

- Need electron rejection power of at least 10^{-9} to start a 10 kg experiment
- Cryogenic approach can elicit deep responses from a silver bromide crystal

AgBr crystal in room temperature

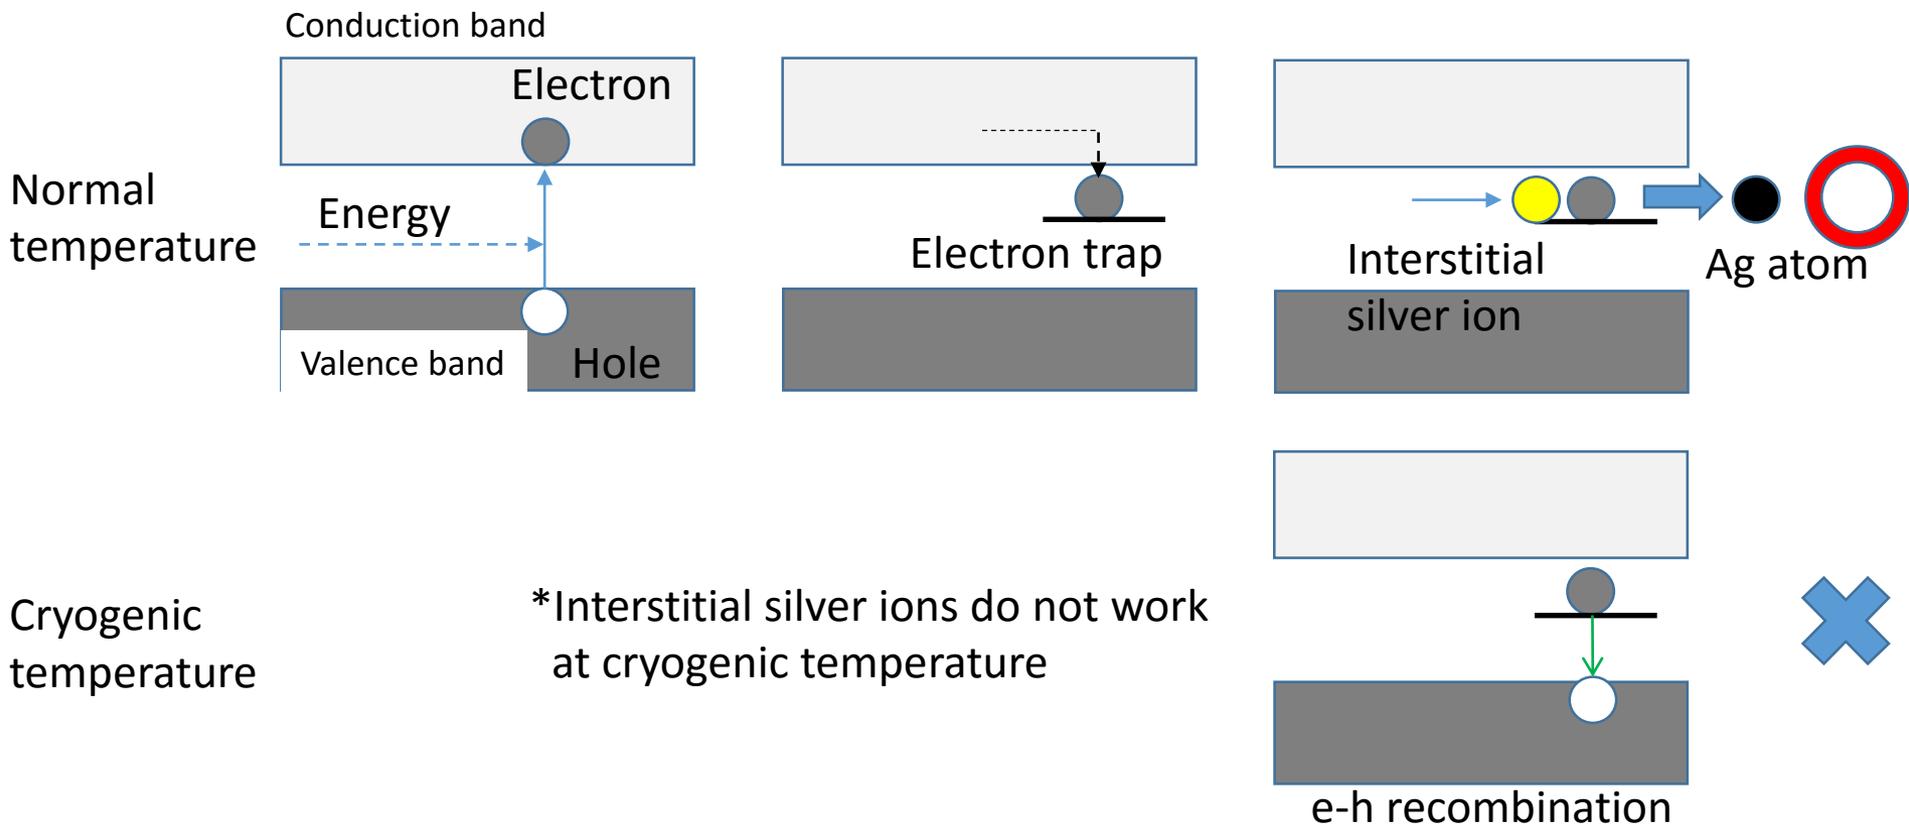

In cryogenic temperature

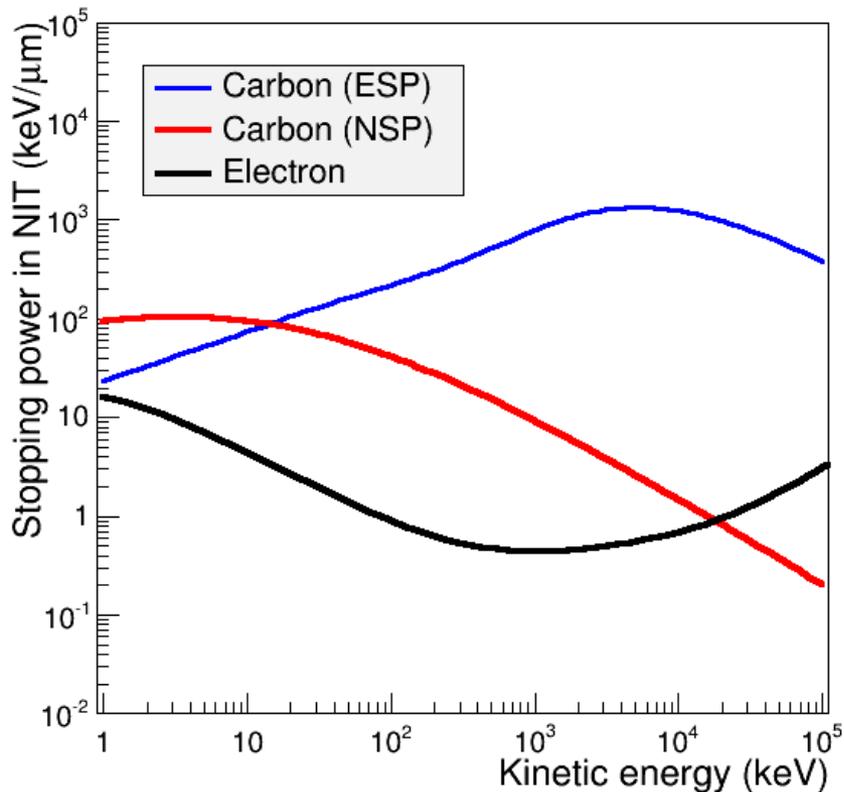

Emulsion sensitivity to electron at cryogenic temperature

- The sensitivity to electrons reduces with decreasing temperature

Nuclear recoil track

- Nuclear recoil tracks have large stopping power

Stopping powers of C⁺ and electrons in NIT according to SRIM and ESTAR (NIST)

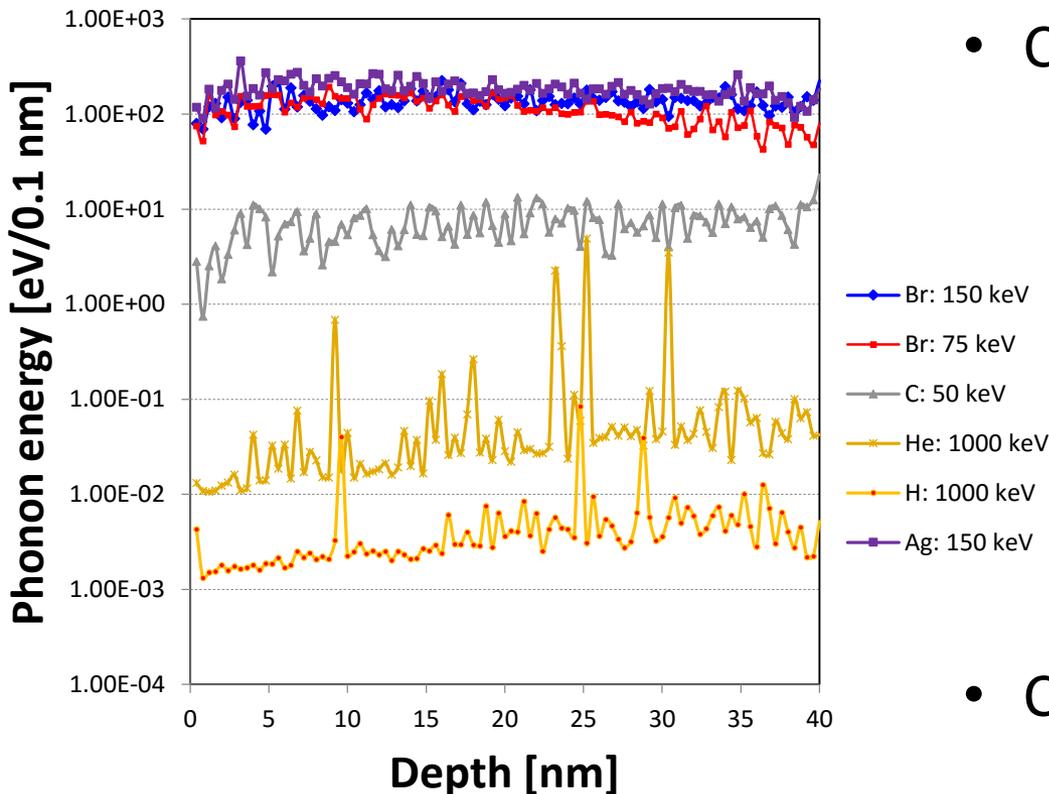

Total stopping power

$$= \text{Electron stopping power (ESP)} \\ + \text{Nuclear stopping power (NSP)}$$

- Electron stopping power (ESP)
 - collision with electrons
 - ionization
- Nuclear stopping power (NSP)
 - collision with atoms
 - phonon
 - **crystal temperature rise**
 - **lattice defect production**

Temperature rise due to phonon effect

- Local temperature rise can recover sensitivity loss

Average phonon energy in 40 nm AgBr layer by various particles (simulated by SRIM)

- Case 1: Uniform temperature rise

	Total phonon energy in 40 nm [eV]	δT for 40 nm AgBr [K]
Ag (150 keV)	18600	58
Br (150 KeV)	13800	43
C (50 keV)	734	2.3
He (1000 keV)	15.9	0.050
H (1000 keV)	0.54	0.0017

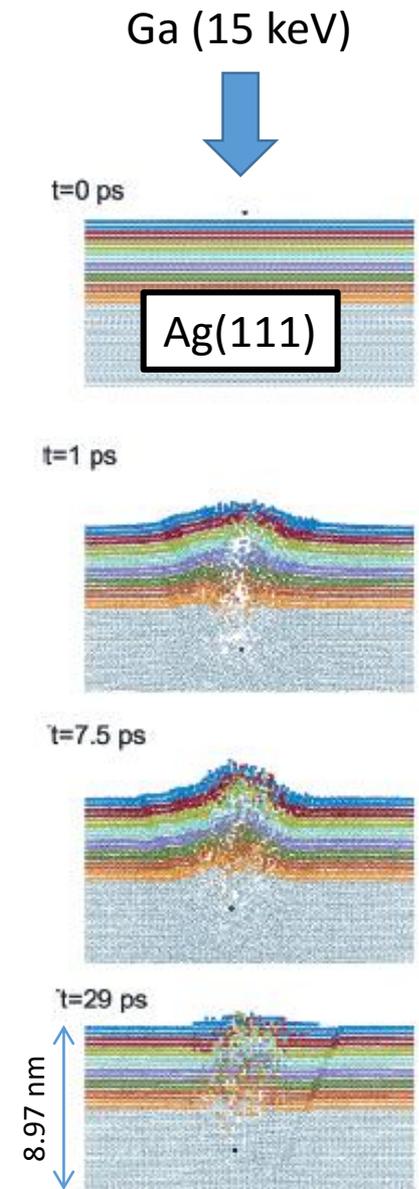

- Case 2: Local temperature rise

$$\Delta T = 10^4 \text{ K for } 10^{-11} \text{ sec due to thermal spike}^*$$

*J.A. Brinkman, Journal of Applied Physics **25**, 961 (1954)

Lattice defect production

- Nuclear stopping power induces atomic displacement
 - produce lattice defect in a crystal*
 - the defect acts as a site of latent image formation
 - the site forms latent image specks efficiently and recover sensitivity

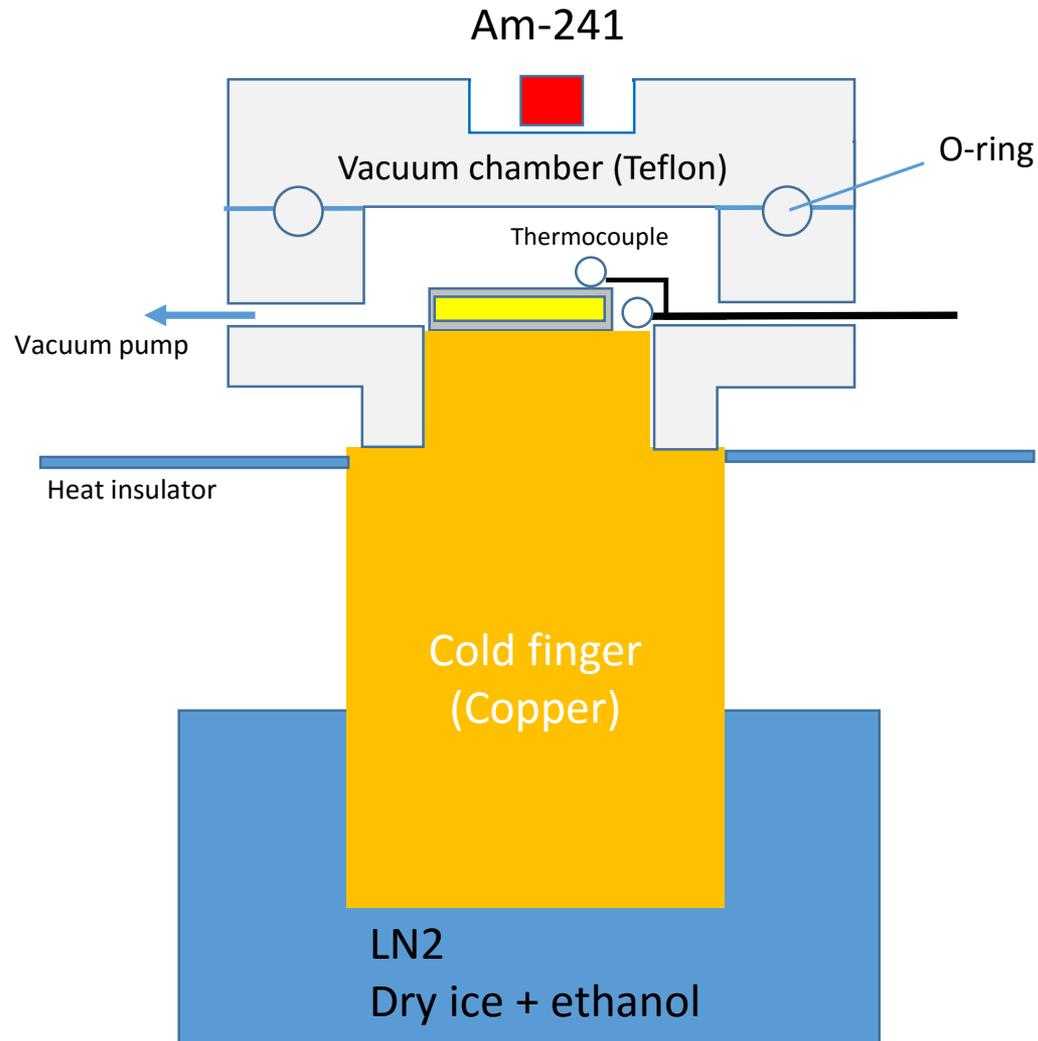

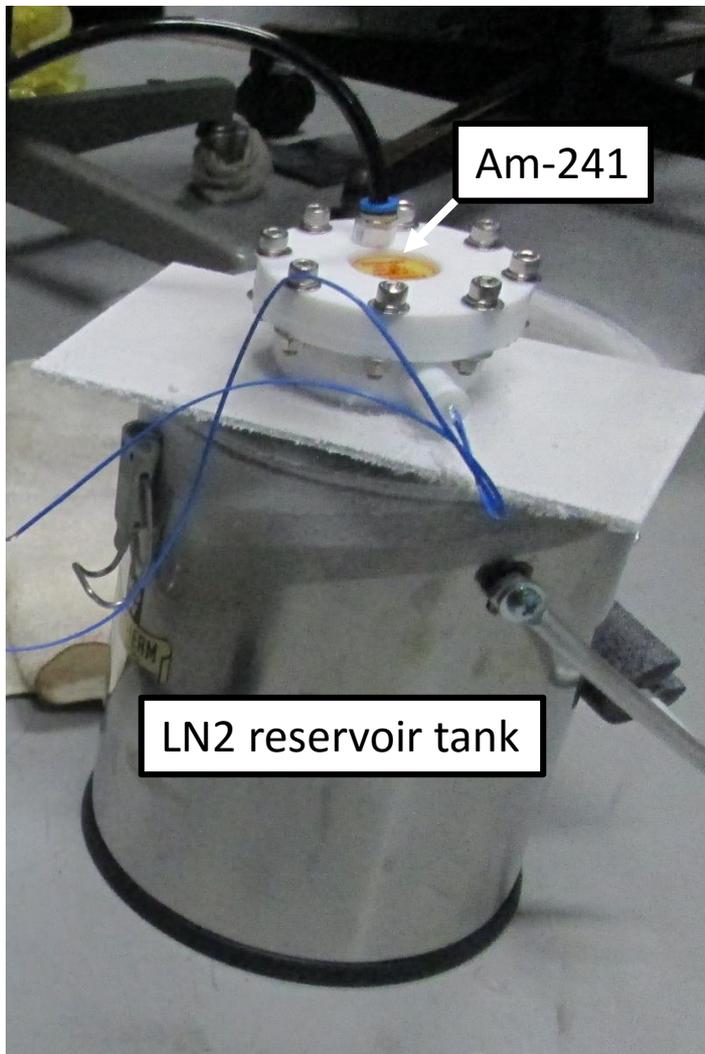

Atomic displacement by a Ga ion on molecule dynamics simulation
J. Phys. Chem. B 2004,108, 7831

*T. Naka *et al.*, Jpn. J. Appl. Phys. 52 (2013) 112601

Test for sensitivity measurement

- Aim to quantify the effect of low temperature on the sensitivity to electron
- Experimental condition
 - Emulsion (with halogen acceptor sensitization)
 - Nano Imaging Tracker (NIT) : 40 nm size AgBr crystal
 - Temperature : 77 – 293 K
 - Vacuum : less than 0.02 atm (water vapor pressure)
 - remove the fading effect
 - avoid accumulating frost on the surface
 - Radiation rays :
 - ^{241}Am (2.9 MBq) : 20 and 60 keV γ

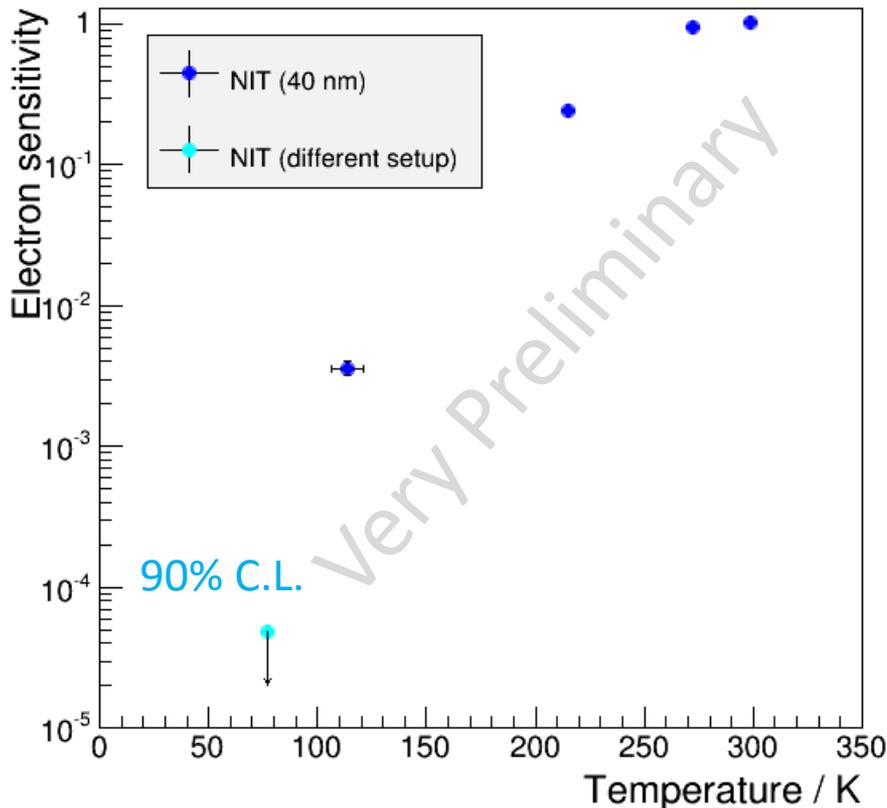

Experimental arrangement

Cross section view of the cryostat

Sensitivity to electron

No sensitivity to electron(ESP 15 keV/ μm) at LN₂ temperature

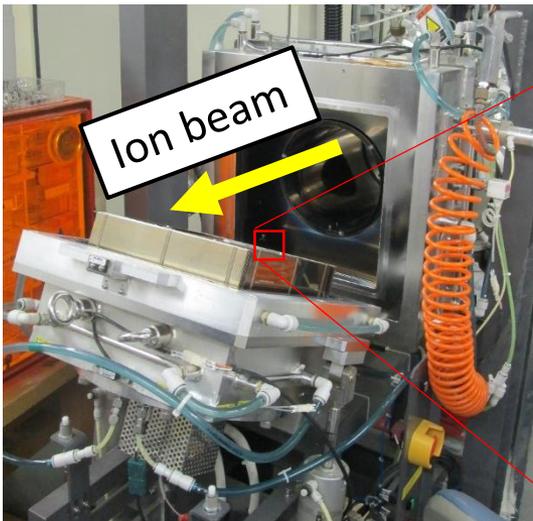

- Development condition
 - MAA 5 °C 10 min
 - Without post-fixed physical development (PPD)
- Evaluation method
 - Count the number of grains in 1000 μm^3 by visual inspection
 - Calculate ratio to the expected number of electrons per 1000 μm^3

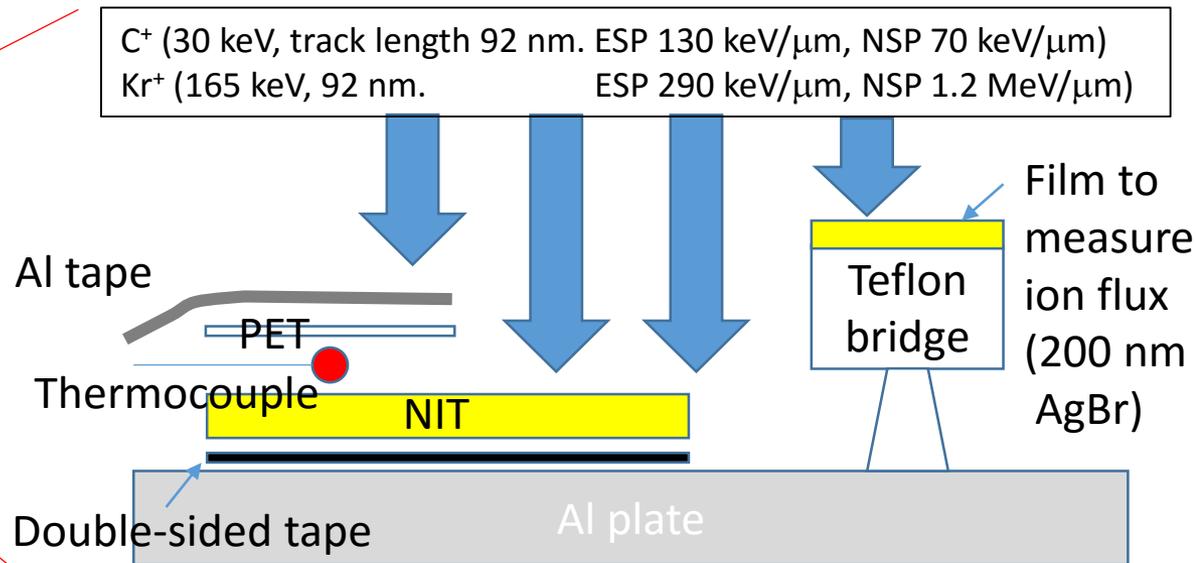

Electron rejection power will be roughly the squared sensitivity
< $(5 \times 10^{-5})^2 = 3 \times 10^{-9}$ at 77 K.

Sensitivity measurement for ions

- Aim to measure the sensitivity to light and heavy ions at cryogenic temperature
- Use an ion implant system at Kanagawa University
 - Emulsion temperature reaches to 93 K (-180 °C)

Ion implant system
at Kanagawa University

Cross section view of setup

Sensitivity to ions

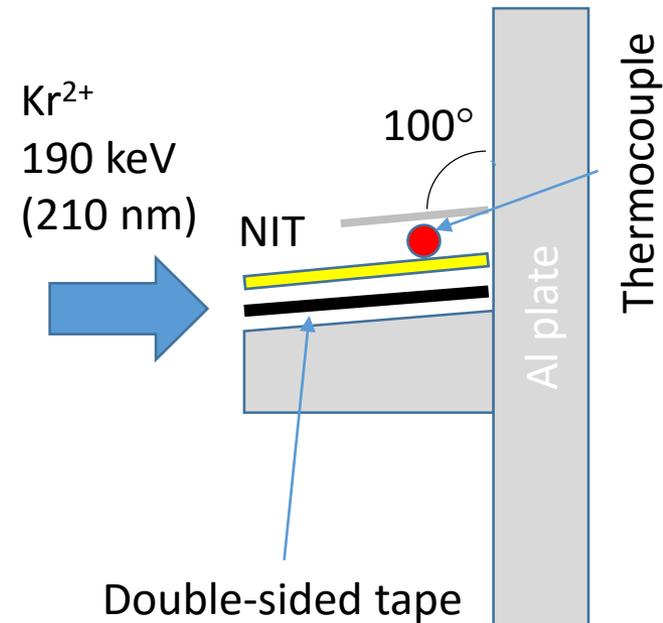

- Prepare treated PPD- and untreated PPD samples
 - PPD increases the size of grains to be easily observed
 - indicates intrinsic detection efficiency
- Measure the number of grains per cm^2 by eye

Kr⁺ 165 keV	Measured (cm^{-2})	Detection efficiency
Flux monitor	$(11.0 \pm 0.3) \times 10^7$	-
Without PPD	$(1.31 \pm 0.08) \times 10^7$	0.119 ± 0.008
With PPD	$(3.0 \pm 0.2) \times 10^7$	0.28 ± 0.02

C⁺ 30 keV	Measured (cm^{-2})	Detection efficiency
Flux monitor	$(9.9 \pm 0.3) \times 10^7$	-
Without PPD	$(0.71 \pm 0.04) \times 10^7$	0.072 ± 0.005
With PPD	$(1.29 \pm 0.09) \times 10^7$	0.13 ± 0.01

Ion tracking with cryogenic nuclear emulsion

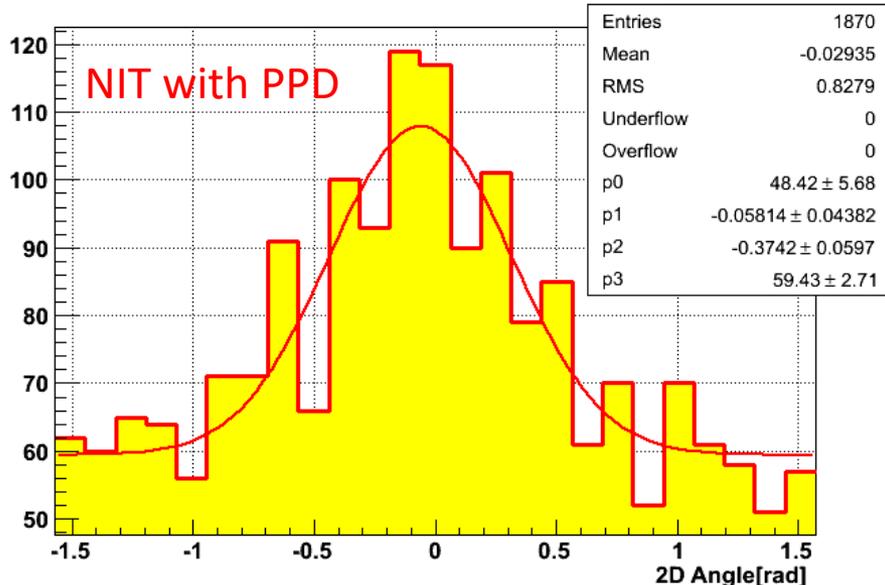

- Aim to measure angular distribution at cryogenic temperature
- Exposure condition
 - Emulsion temperature: 95 K (-178 °C)
 - Ion type: Kr^{2+} with 190 keV
(track length = 210 nm)
 - Exposure density: $1 \times 10^9 \text{ cm}^{-2}$

Angular distribution in NIT

- Treated PPD
- Scan the sample by the automatic scanning system
- Enable to measure track angle at cryogenic temperature

Angle distribution, $E_{li} >= 1.4$, bin=25, 30 deg.shift

Temperature	Beam	Angular resolution
293 K	C ⁺ 80 keV (expected range 240 nm)	0.41 ± 0.01 rad
95 K	Kr ²⁺ 190 keV (210 nm)	0.37 ± 0.06 rad

* Both samples are treated PPD

Conclusions

- Fine-grained nuclear emulsion is a promising detector for directional dark matter search
- We propose cryogenic approach to remove electron background events coming from ^{14}C decays
- For proof of principle we irradiated NIT with γ rays and ions at LN_2 temperature
 - no sensitivity to electron
 - NIT has sensitivity to low speed ions (C^+ , Kr^+)
 - not concordant with the simplest hypothesis (uniform temperature rise)
 - track angle can be measured

Future prospects

- Preparation of emulsion dark matter experiment is under way at LNGS underground
 - a 1 kg experiment will start from Oct. 2018
- We will measure emulsion properties to propose introducing the cryogenic approach
 - tracking efficiency as function of energy
 - long term stability at cryogenic temperature (mechanical stress, sensitivity, fog noise ...)
 - study cooling method for a 1 kg emulsion

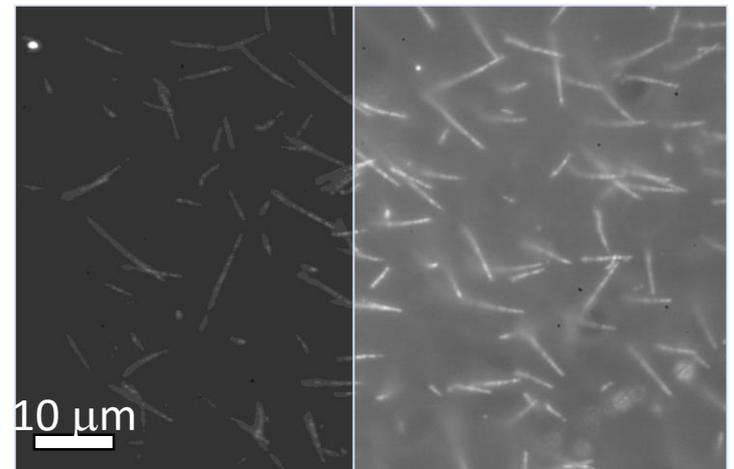

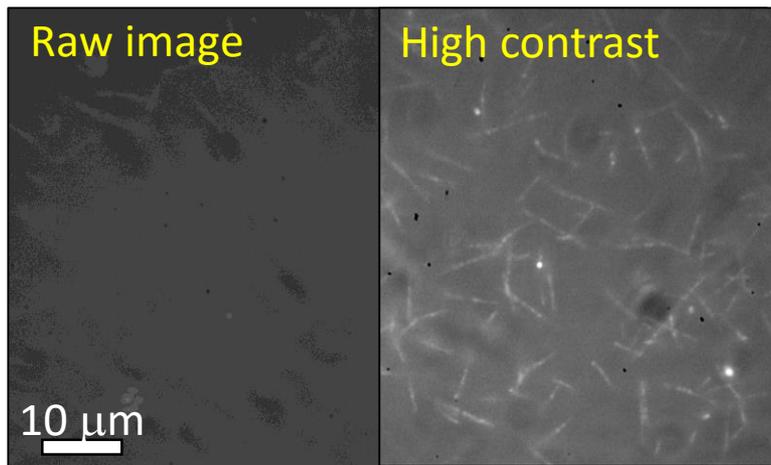

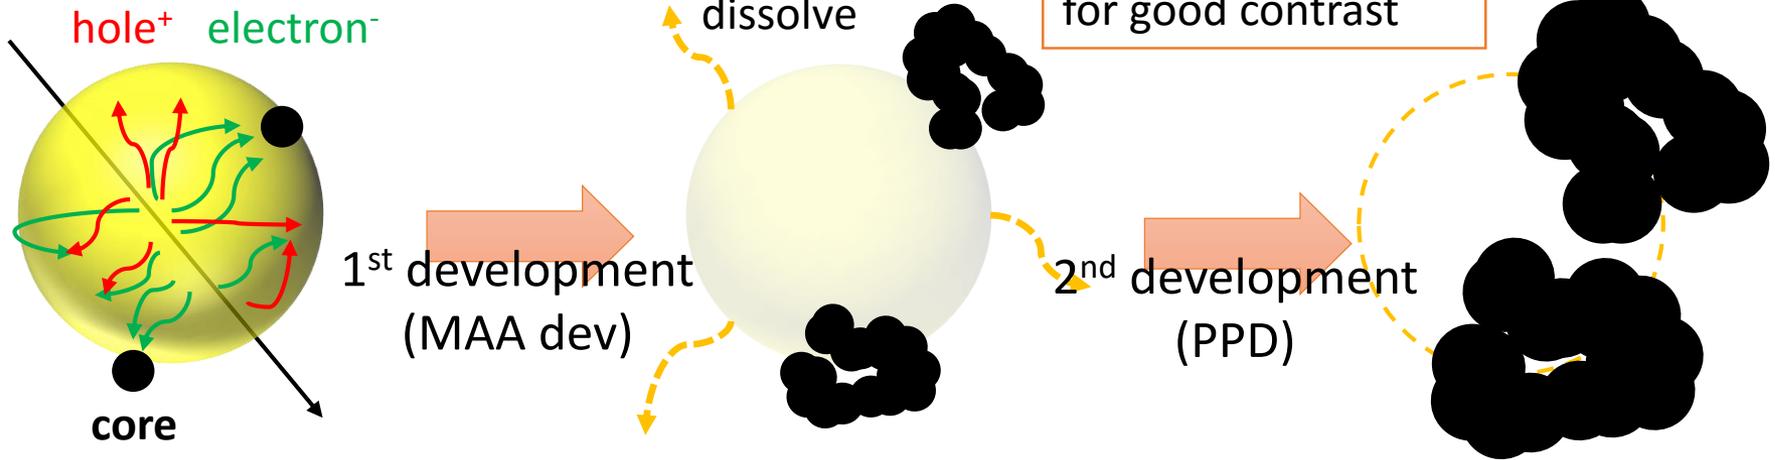

Acknowledgement

- We would like to thank Prof. Dr. Nakata and his students at Kanagawa University for the ion exposures
- We appreciate helpful discussions with Dr. Tani and Prof. Dr. Kuge

Development process

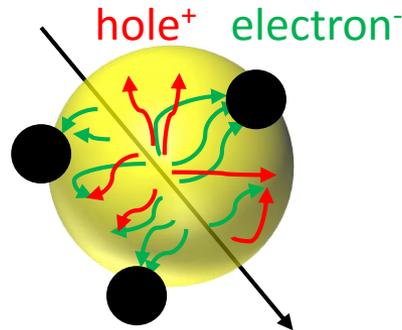

Sensitive development

Strong development for good contrast

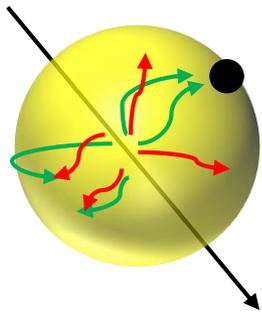

α tracks from Am-241

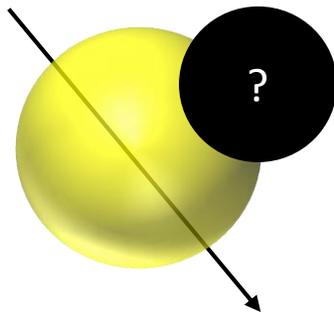

Type of event sources

- Signal events (recoil nuclei)
 - dE/dx : 100 – 1000 keV/ μm
 - Many e-h pairs \rightarrow strong signal

- Background event (electron)
 - dE/dx : 1 – 10 keV/ μm
 - A few e-h pairs \rightarrow weak signal

- Noise event (thermal excitation, dust)
 - Thermal excitation: random single grain
 - Dust: strange shape (not round)

(α , n) from ^{238}U chain	0.24 ± 0.07
Spontaneous fission	0.75 ± 0.22
Total flux	1.10 ± 0.32

Nuclear recoil induced by neutrons

(> 100 nm tracks)

$\Rightarrow 0.065 \text{ kg}^{-1}\text{year}^{-1}$

Environmental neutron

Studies of the flux measurement and shielding plan are in progress

Other neutron sources

- Neutrons from environmental radioactivity

Should be reduced to a negligible level with appropriate shielding; to be studied.

- Cosmic muon-induced neutrons

Under evaluation; in underground sites is expected be less than the one from intrinsic radioactive contamination (preliminary rough estimation)

Approximations and assumptions:

Neutron differential spectrum: 10^{-5} n/ μ /g/cm²/MeV

Material used in the simulation is C_nH_{2n}

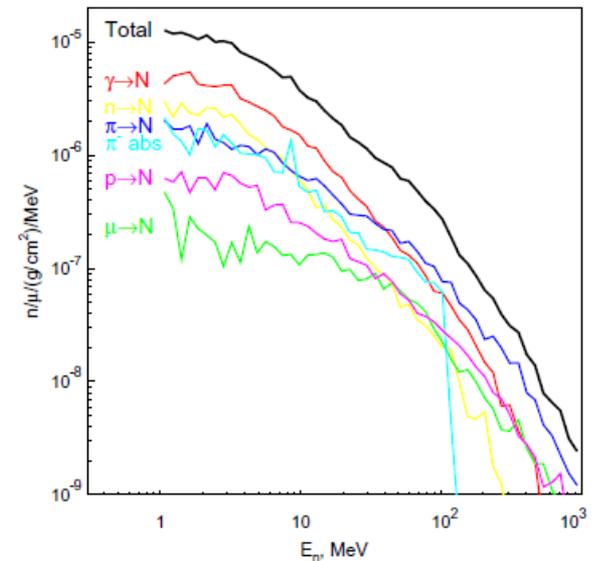

20 kg of emulsions

Muon flux: 1/m²/h

Neutron flux: 0.18 n/y/MeV → 0.009 n/kg/y/MeV

With a rough integration from 0 to 10 MeV → about 0.05 n/kg/y

Differential energy spectrum of neutrons produced by 280 GeV muons

Applications of luminescence

(To be investigated fundamental properties)

- For DM
 - position trigger for large size emulsion detector
 - nuclide identification
- For other experiments
 - time resolution (→ the AEgIS experiment)
 - fluorescence emission solid-type tracking detector
 - + super resolution technique (e.g. STORM)

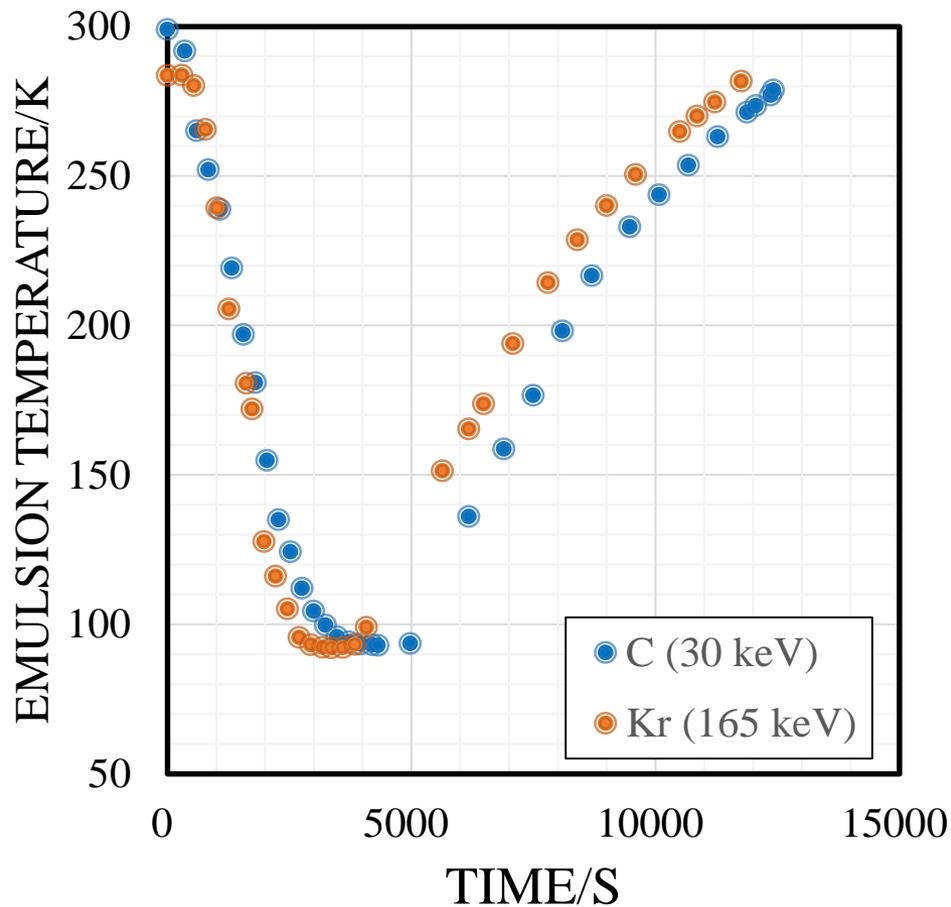

Possible design

Soak emulsion films in LN2 directly → good mass scalability

Emulsion temperature

- Temperature reaches to 93 K (-180 °C)

1 hour to cool down
3 hours to warm up
