

# Recent Developments with Microchannel-Plate PMTs

**Albert Lehmann,**  
Merlin Böhm, Markus Pfaffinger, Fred Uhlig  
(Universität Erlangen-Nürnberg)  
for the PANDA Cherenkov Group

- Introduction and motivation
- Properties of new 2" Hamamatsu MCP-PMT
- Status of aging test results
- Trying to understand PC aging mechanism
- Outlook and summary

# PANDA Detector at FAIR

# MCP-PMTs for PANDA DIRCs

- MCP-PMTs are the only suitable sensors for PANDA

- Compact and available as multi-anode devices
- Single photon detection even in B-fields of >1 Tesla
- Excellent time resolution <50 ps
- Low dark count rates

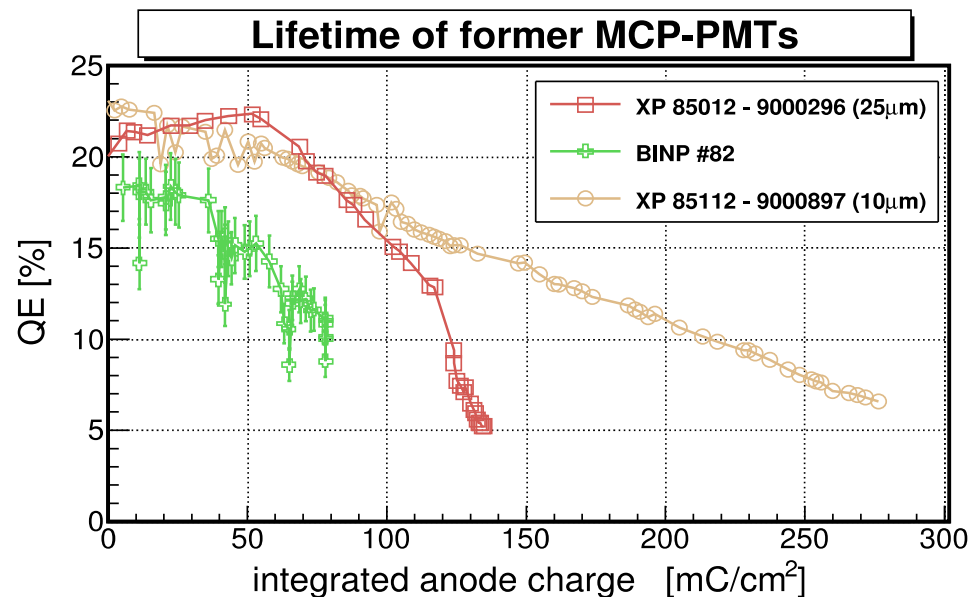

- Barrel DIRC

- Pixel size:  $\sim 6 \times 6 \text{ mm}^2$
- Photon rate:  $\sim 200 \text{ kHz/cm}^2$
- **10 years anode charge:  $5 \text{ C/cm}^2$**

- Endcap DIRC

- **Pixel size:  $\sim 0.5 \times 16 \text{ mm}^2$**
- Photon rate: up to  $1 \text{ MHz/cm}^2$
- **10 years anode charge:  $>5 \text{ C/cm}^2$**

**Status in 2011**

# Attempts to Reduce Aging

- Improved vacuum quality
- Cleaning of MCP surfaces by electron scrubbing techniques
- Thin (5-10 nm)  $\text{Al}_2\text{O}_3$  films before or between MCPs [NIM A629 (2011) 111]
- Modified and more robust photo cathodes [JINST 6 C12026 (2011)]
- Deposition of ultra-thin atomic layer (MgO,  $\text{Al}_2\text{O}_3$ ) on MCP substrate
  - Arradance Inc. → PHOTONIS, LAPPD, ...
  - MCP pores are coated in three steps
    - resistive layer
    - secondary electron emission (SEE) layer
    - electrode layer
  - Optimization of MCP resistance and SEE
    - for each film independently
    - higher gain at given HV

**!! most successful !!**

# Simultaneous Aging of MCP-PMTs

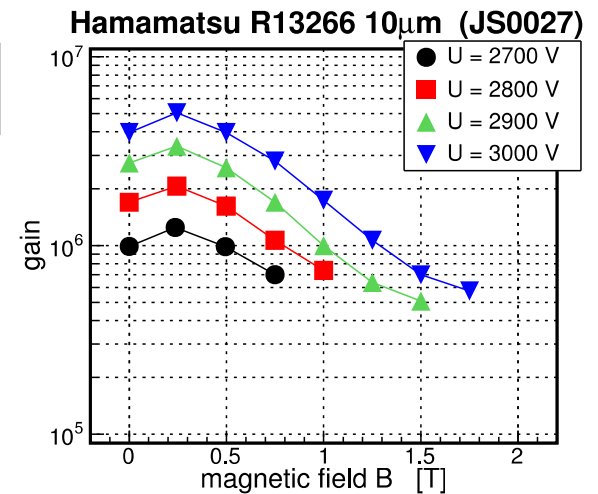

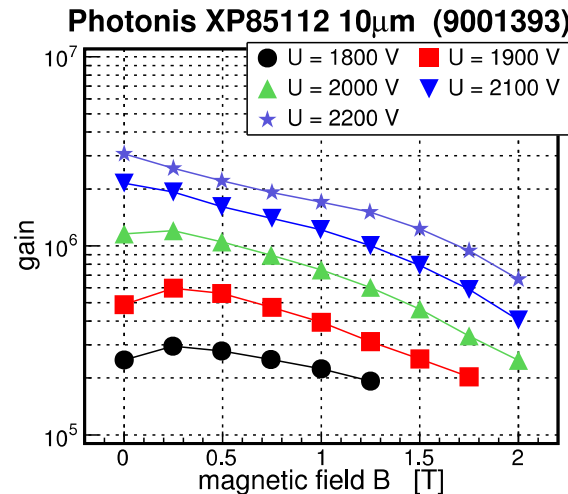

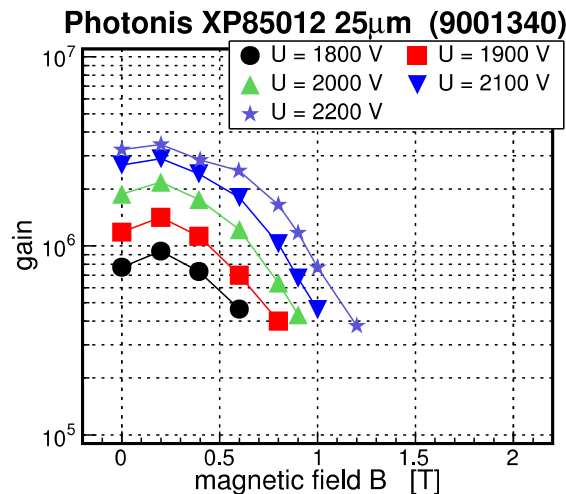

- **Problem in 2011:** The few aging tests existing were done in rather different environments → results are difficult to compare
- **Goal:** measure aging behavior for all available lifetime-enhanced MCP-PMTs in same environment
- **Simultaneous illumination** with common light source → same rate
- **Aging results presented at RICH 2013:**

**ALD technique is superior**

# Gain of ALD Tubes

Non-ALD

ALD

- Tendency of faster gain drop inside magnetic fields in ALD tubes
- Reason could be higher SEE coefficients  $\rightarrow$  earlier saturation

# 2 inch Multi-Anode MCP-PMTs

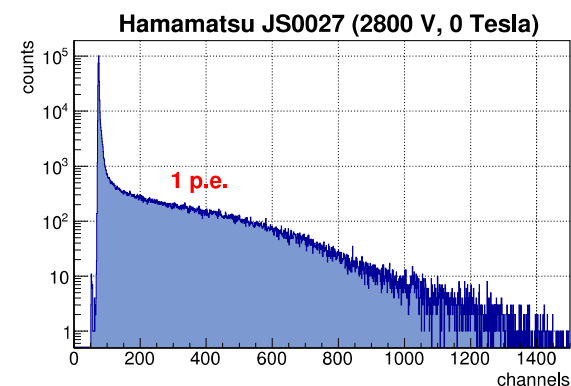

## ● Photonis

- Layout existent since Burle Planacon
- ALD surfaces; **no film**
- active area ratio: 81%
- Available as **8x8** (Barrel DIRC) and **3x100** (Endcap DIRC) pixel versions

## ● Hamamatsu

- **First prototypes** developed in **2014**
- ALD surfaces + **film in front of 1<sup>st</sup> MCP**
- Slightly less active area ratio: 70%
- Available as **8x8** (Barrel DIRC) and **6x128** (Endcap DIRC) pixel versions

# Readout of 128x6 Hamamatsu MCP

MCP backplane with 12 blocks of 64 pins each:  
rather difficult readout for characterization (not yet ASICs)

MCP backplane with one readout board:

- Covers 3 64-pin blocks
- Lower side: three 0.05" Samtec plugs with 4x20 pins (FOLC-120-02-L-Q)
- Upper side: three 0.05" Samtec plugs with 2x40 pins (LSHM-140-02.5-L-DV-A-S-TR)

Adapter board for 64 pins from 0.05" to 0.10" pitch

MCP backplane with four readout boards connected

80-channel coax-cable connects to 1 adapter board

Possibility to read out single blocks directly or up to all 768 channels simultaneously with coax-cables

# Properties of 2" Hamamatsu (8x8)

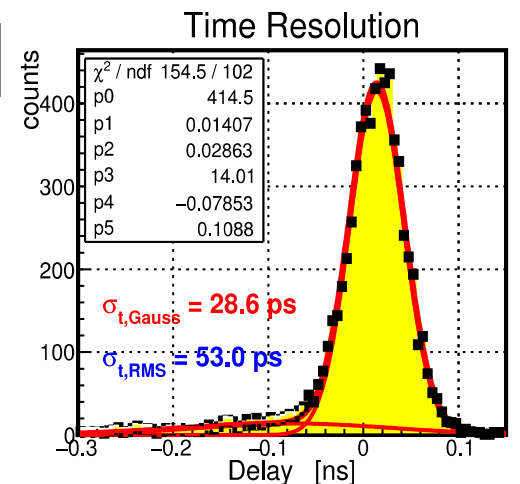

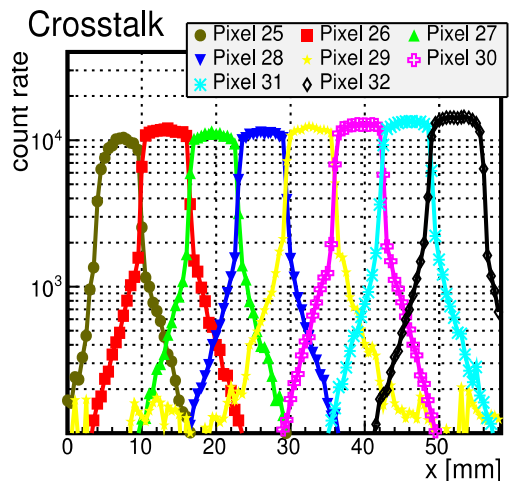

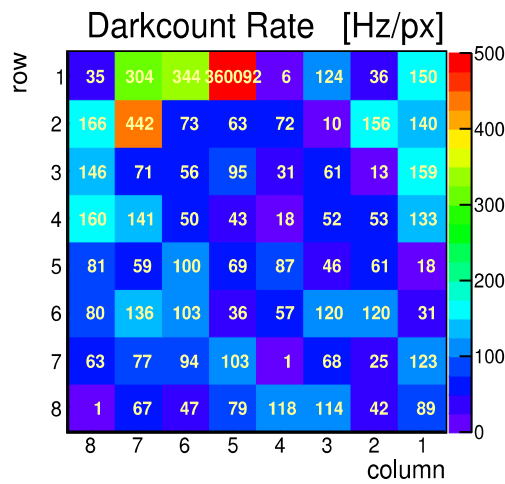

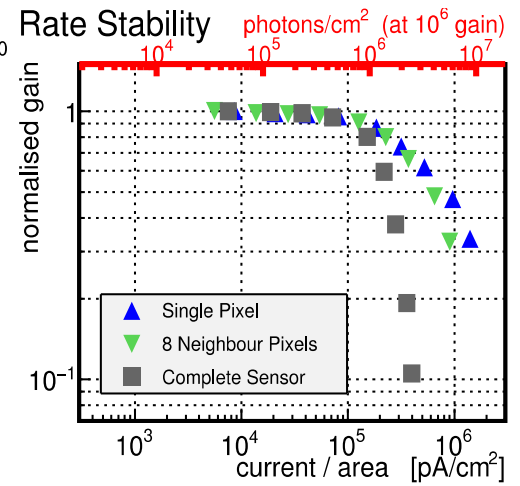

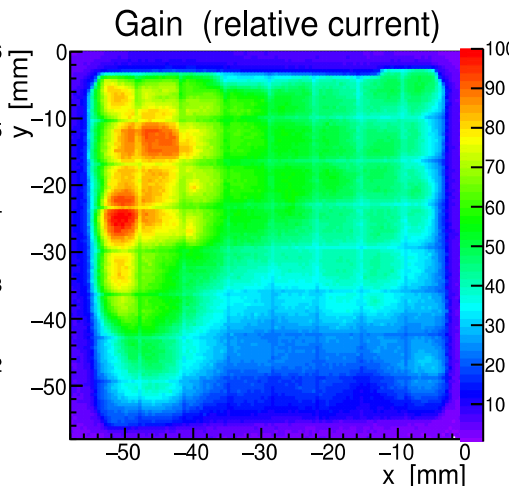

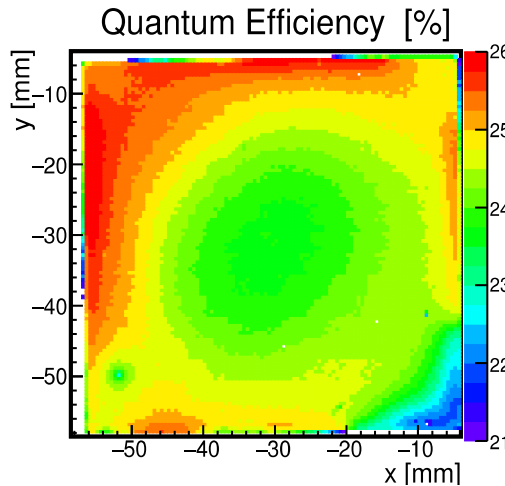

**JS0035**

still negative

- QE homogeneity improvable
- Gain very non-homogeneous
- Rather low rate capability

positive

- Very low dark count rate
- Good cross talk behavior
- Excellent time resolution

**New 2" Hamamatsu MCP-PMT (R13266) prototype shows promising features with room for improvement**

# Measure Width of Charge Cloud

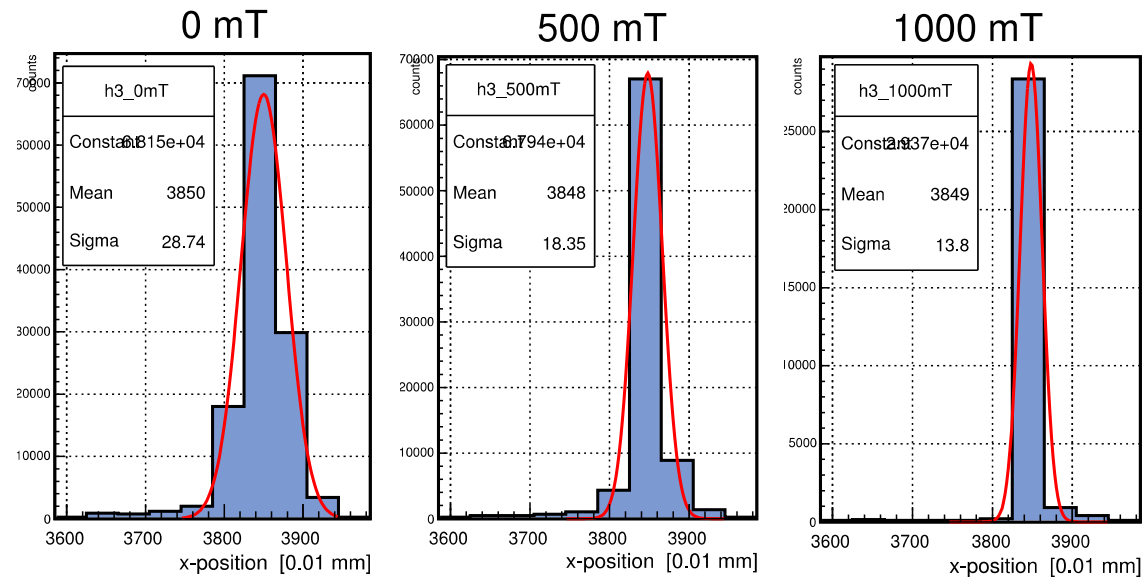

T. Gys, NDIP 2014

● Hamamatsu 6x128 pixels inside magnetic field

- Illuminate 1 pixel with  $<50 \mu\text{m}$  focus
- Read out 8 adjacent pixels (0.4 mm pitch)
- Measure counts above a certain threshold (10 chan.  $\sim 0.04$  p.e.)
- Plot distribution as a function of the magnetic field
- Width of distribution shrinks with increasing B-field

● **0.3 mm FWHM resolution at 1 T**

Width of Charge Cloud

# Crosstalk and Position Resolution

- Hamamatsu MCP-PMT with 6x128 pixels inside magnetic field

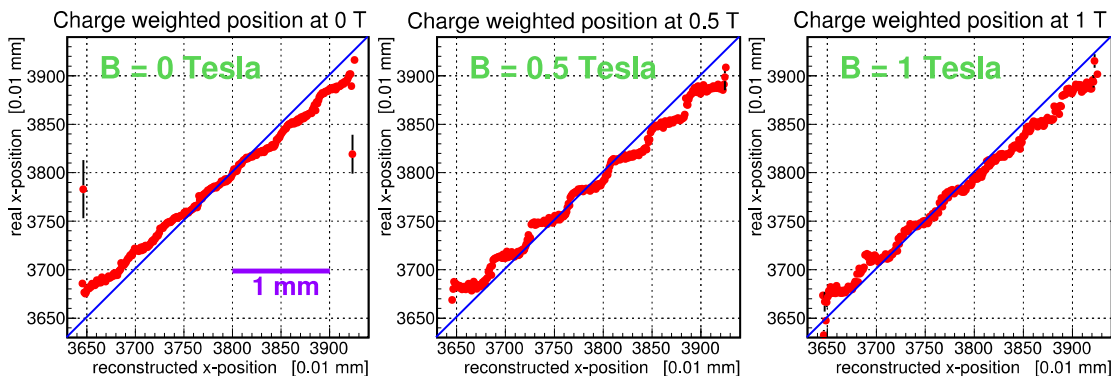

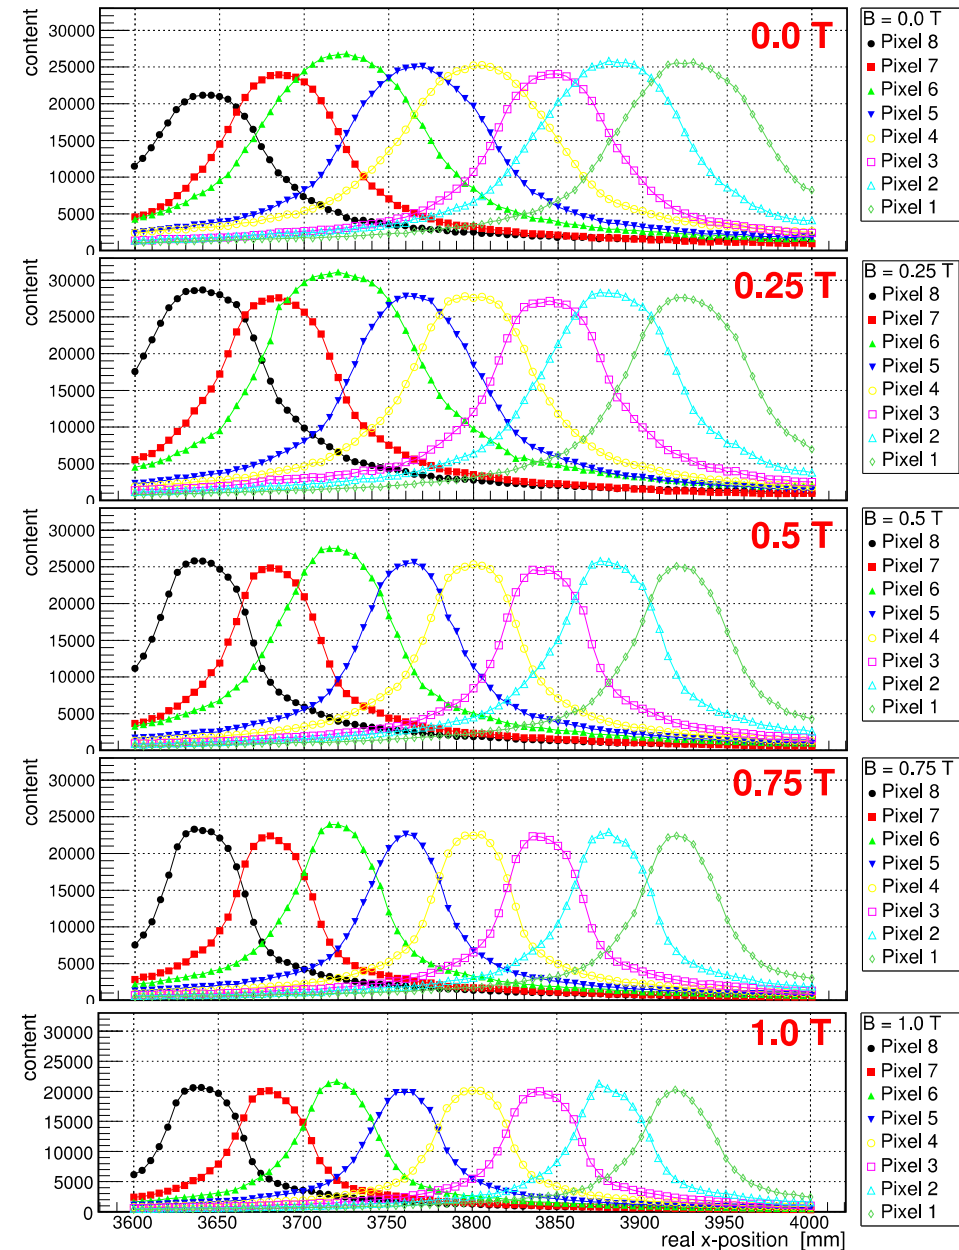

- Diameter of laser spot <math>< 50 \mu\text{m}</math>
- Read out 8 adjacent pixels (0.4 mm pitch)
- Plot counts in each pixel at given laser position (thresh = 0.04 p.e.; 50  $\mu\text{m}$  steps)

- Position resolution

- Rather long tails  $\rightarrow$  **electronic crosstalk?**
- Photonis MCP-PMTs looks better  $\rightarrow$  Talk M. Düren
- Peak width gets smaller at higher B-field

- Good linearity with charge weighting

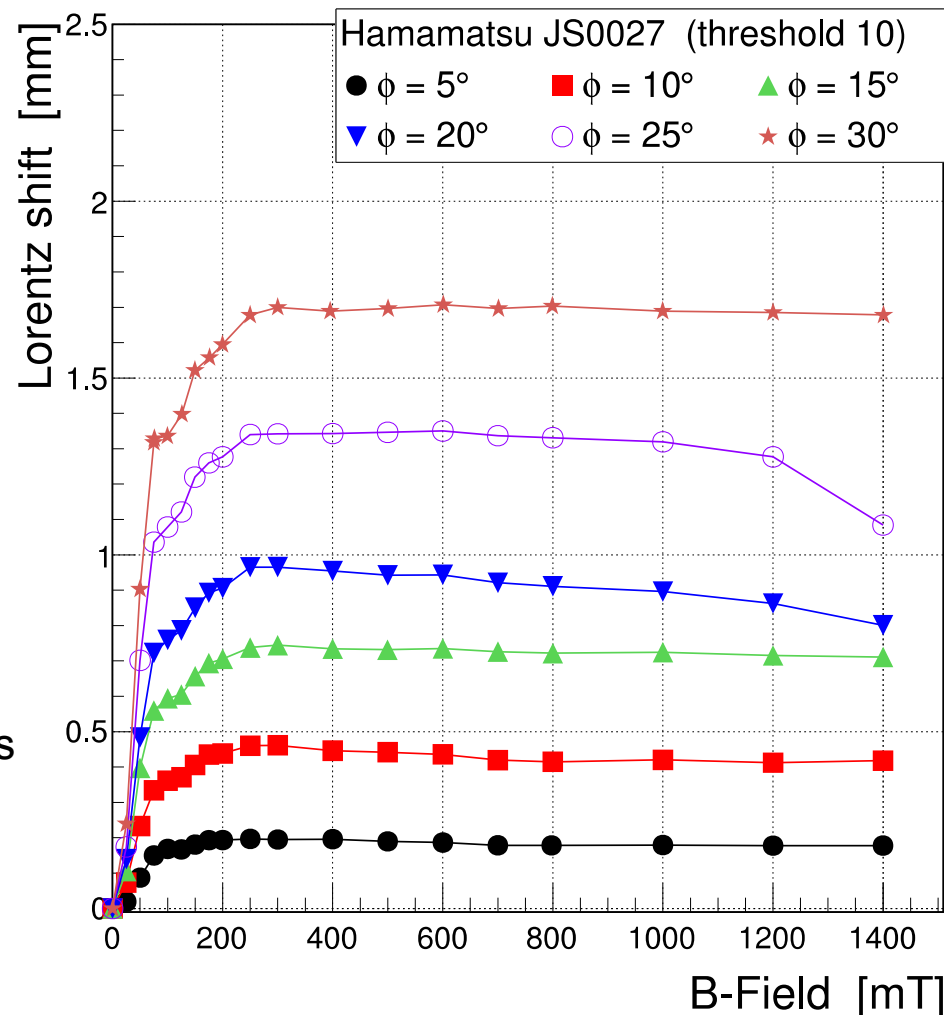

- Off at sides because of limited number of anodes

# Measure Lorentz Shift in MCP-PMT

## Shift of Charge Cloud Centroid

## Hamamatsu MCP-PMT with 6x128 pixels inside magnetic field

- Diameter of laser spot <math>< 50 \mu\text{m}</math>
- Always point laser to same pixel (at  $\Phi = 0^\circ$ )
- Read out 8 adjacent pixels (0.4 mm pitch)
- Calculate charge weighted position along tilt axis
- $\rightarrow$  **measures Lorentz shift inside B-field**

## Position shift

- Saturation reached at  $\sim 0.25$  Tesla
- Maximum shift of 1.7 mm ( $\sim 4$  pixels) at  $\Phi = 30^\circ$

# Measurement of MCP Lifetime

## Continuous illumination

- 460 nm LED at 0.25 to 1 MHz rate attenuated to single photon level  
→ 3 to 20 mC/cm<sup>2</sup>/day

## Permanent monitoring

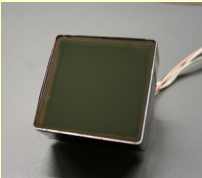

- MCP pulse heights and LED light intensity

## Q.E. measurements

- 250–700 nm wavelength band with monochromator  $\Delta\lambda = 1$  nm
- Every 2-3 weeks (first days): wavelength scan
- Every 3-4 months (first weeks): complete surface scan at 372 nm

# of tubes measured	<b>2</b>	<b>1</b>	<b>1</b>	<b>3</b>	<b>1 (+1 L4)</b>	<b>2</b>	<b>1</b>
							

- Tubes first measured with no significant lifetime improvements
- Lifetime improved tubes measurement started ~5 years ago
- Hamamatsu 1 inch ALD tubes measurement started ~3 year ago
- Hamamatsu 2 inch ALD tube started in Dec. 2015

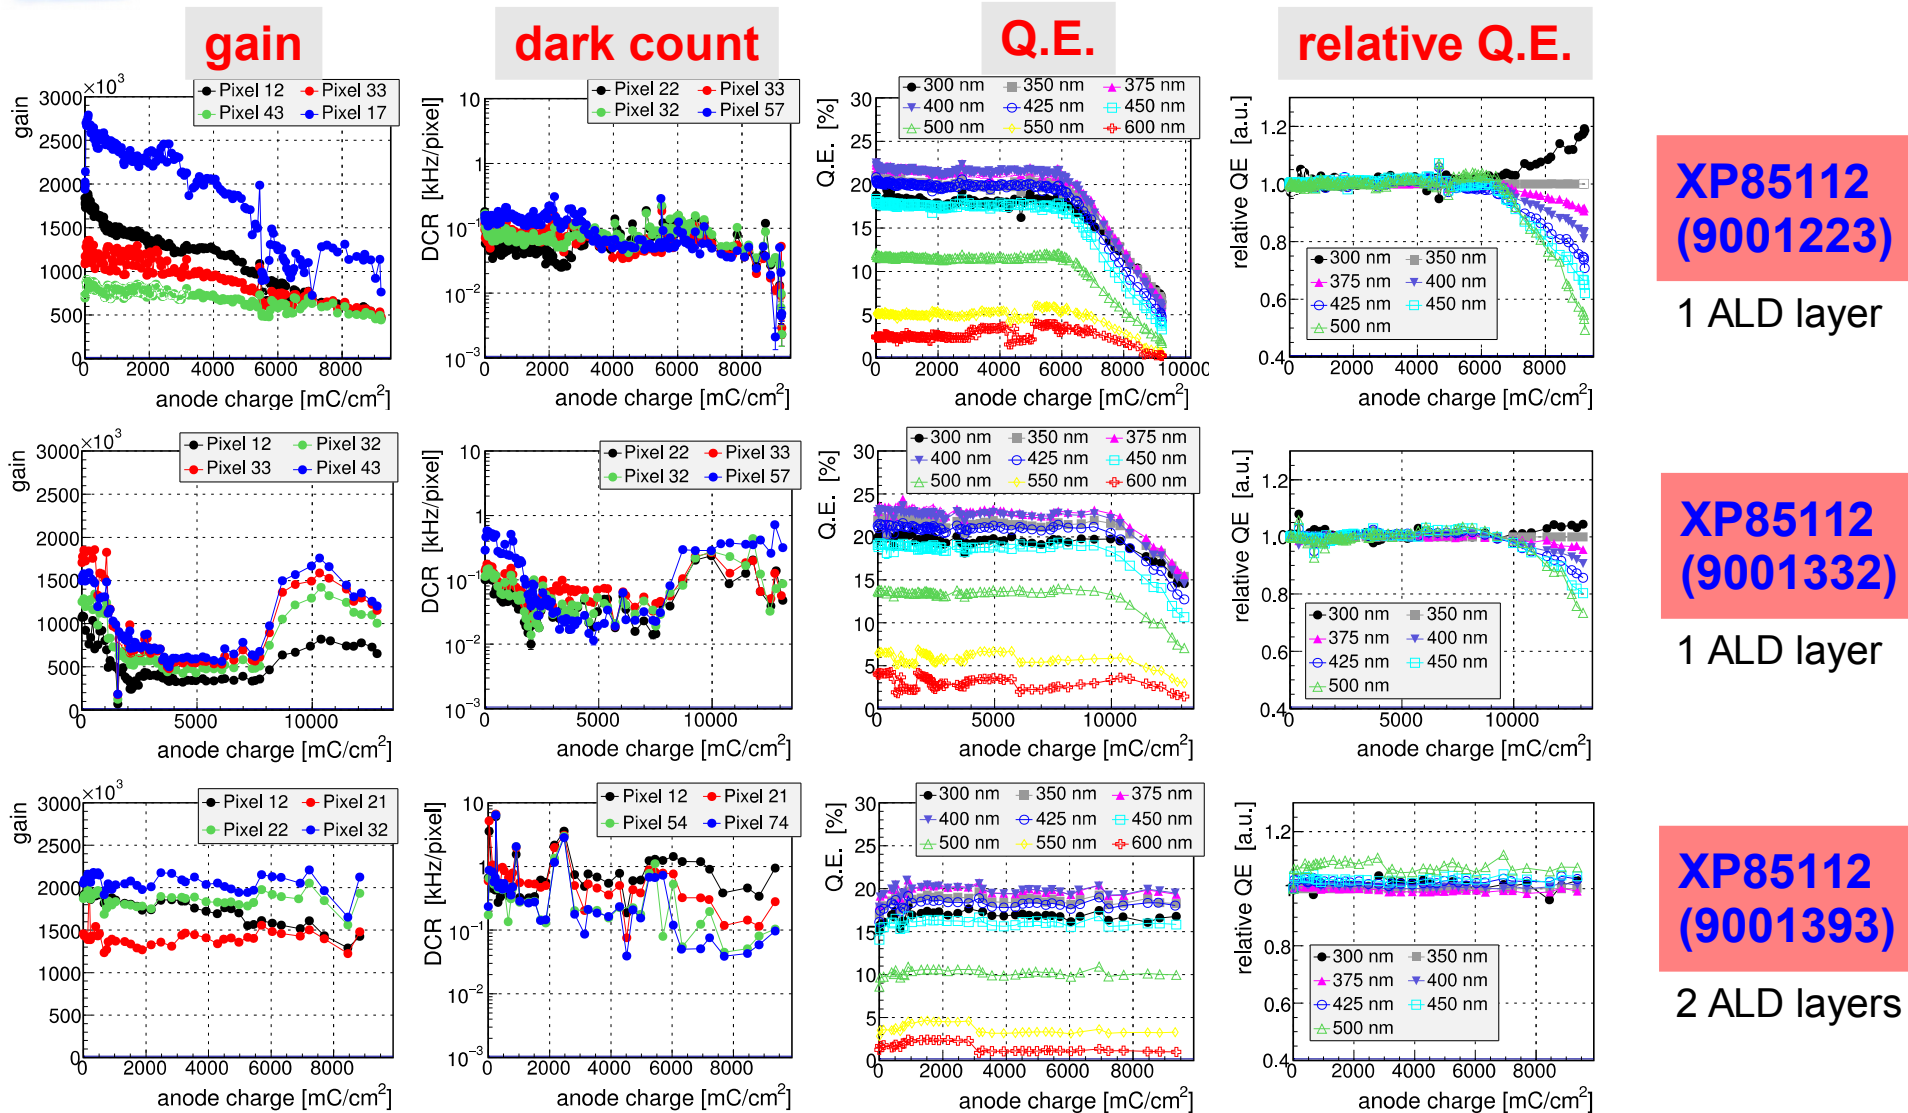

# Lifetime of MCP-PMTs (Aug. 2016)

- Hamamatsu film MCP-PMT: Q.E. drops beyond 1 C/cm<sup>2</sup>
- Photonis 9001393: no Q.E degrading observed up to ~10 C/cm<sup>2</sup>
- MCP-PMTs with ALD layers: **very good performance to >6 C/cm<sup>2</sup>**

# Gain, DCR and QE (Photonis)

1 layer ALD: gain/DCR variations; QE stable up to 6 and 10 C/cm<sup>2</sup>, then declining

2 layer ALD: very stable behavior up to ~10 C/cm<sup>2</sup>

# Gain, DCR and QE (Hamamatsu)

gain

dark count

Q.E.

relative Q.E.

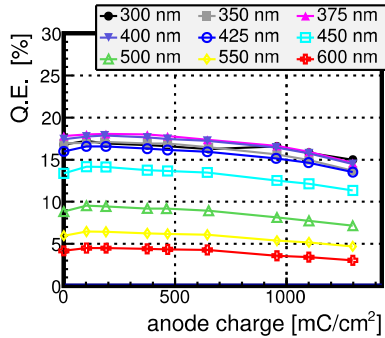

**R10754X-07-M16M (KT0001)**

1 ALD layer  
+ film between MCPs

**R10754X-07-M16M (KT0001)**

1 ALD layer  
+ film between MCPs

**R13266-07-M64 (JS0022)**

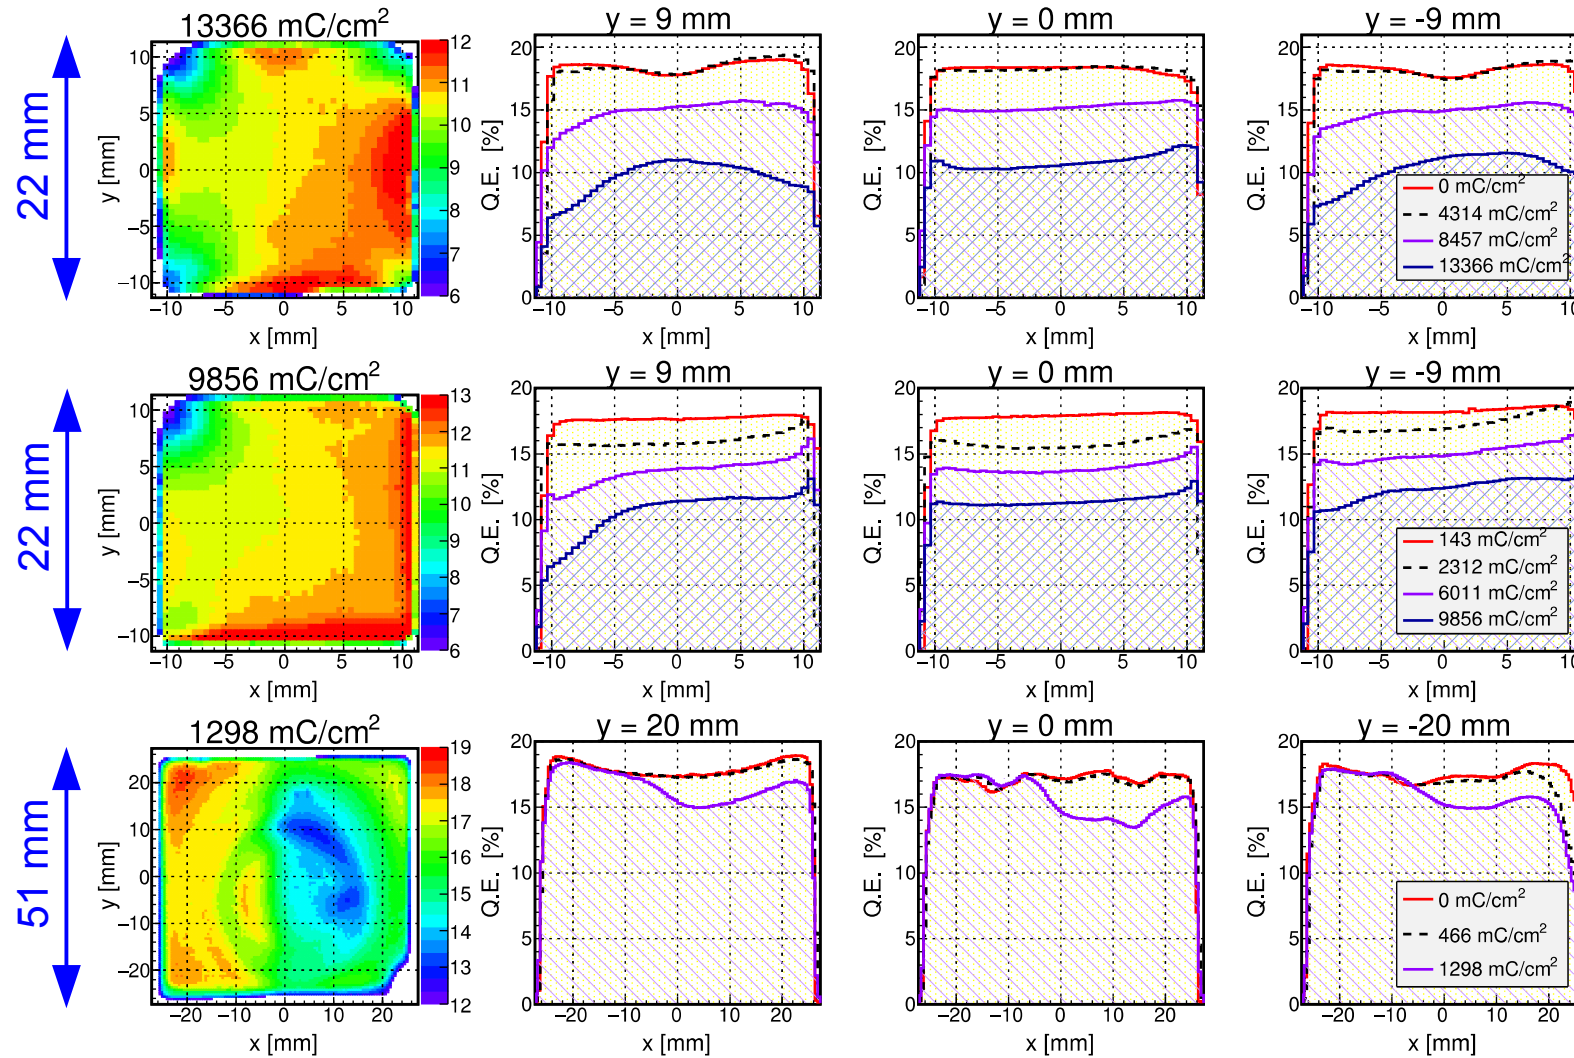

1 ALD layer + film  
in front of 1st MCP

● gain moderately stable and DCR decreases slightly

● Moderate but continuous QE degradation with wavelength dependence

# Q.E. Scans (Hamamatsu ALD)

**Q.E. at 372 nm**

**R10754X-07-M16M (KT0001)**

1 ALD layer  
+ film between MCPs

**R10754X-07-M16M (KT0002)**

1 ALD layer

**XP85112  
(9001393)**  
2 ALD layers

right half of tube  
not illuminated

tube fully  
illuminated

1 ALD layer: QE degradation starts at 6 C/cm<sup>2</sup> and 10 C/cm<sup>2</sup>  
2 ALD layers: no sign of QE degradation up to ~9.4 C/cm<sup>2</sup>

# Possible Causes of MCP Aging

- Neutral molecules from residual gas react with PC [NIM A629 (2011) 111]
- Ion feedback

[Jeff deFazio, 2016]

- Amplification process causes
  - Desorption of atoms from MCP material (especially H and Pb)
  - Damage to MCP surfaces  
→ gain may change
  - Ionization of residual gas atoms

- Ions accelerated towards photo cathode (**ion feedback**)
  - Ions hit and may react with PC
  - Order-of-magnitude ~keV ions
  - Light ions ( $H^+$ ,  $H_nO^+$ ) confirmed by TOF
  - Heavier ions more difficult to identify (expected K, Cs, Pb, Si)
- PC gets damaged → QE loss
  - **Mechanism unknown !**

# Aging Mechanism (Absorption?)

- According to 3-step photo-emission model “damage” may occur on any of the processes related to absorption, diffusion and escape at the surface barrier

- Accessible measurements

- Quantum efficiency (QE)
- p.e. energy distribution with RPA (retarding potential analyzer)
- Optical absorption

- Optical measurements

- Backside (through-substrate) spectroscopic ellipsometry measurements
- Results of 4 quadrants indistinguishable (2 covered, 2 aged)
- Bulk structure unchanged
  - normal e-h pair generation
  - no change in photon absorption
- Big changes in optical absorption could be seen by eye!

[Results from Jeff deFazio, 2016]

# Aging Mechanism (Work Function?)

[Results and conclusions from Jeff deFazio. 2016]

## Work function measurements

- Measure p.e. energy distribution curve: change in electron affinity will expand or compress the range of electron energies between threshold and hottest electrons

## Change in electron affinity (EA) seen

- $\Delta EA \sim 0.13$  eV
- Very similar EDC shape  $\rightarrow$  diffusive energy loss apparently unchanged

## EA impact on QE results

- Upper curves: QE ratio of good PC side for  $K_2CsSb$  photo cathode with different EAs
- EA drop starts at long wavelength, but has minimal impact at lower wavelengths
- QE ratio “aged/masked” is very different  $\rightarrow$  EA increase is not the main reason for aging

9001223 - IV @ 293 nm

QE Ratios

# Aging Mechanism (Sputtering?)

## ● Electron backscattering from MCP

- At long wavelengths the distribution of p.e. energies is very narrow → possibility to **resolve elastic scattering features at MCP surface** (i.e. electrons returning to photocathode) → **Cs sputtered from PC**
- Notable difference between the two PC halves (aged and masked)
- Structures disappear after 18h at 80° C
- But: heating also yields constant QE loss for all  $\lambda$  → **totally different behavior than for ion feedback QE degradation**

## ● Summary

- Bulk structure intact → band structure unchanged → **photon absorption unchanged**
- Only small EA change in EDC → work function ~unchanged → **p.e. escape unaffected**
- Cs ions at MCPs → **sputtering from PC** → cannot explain constant QE loss factor
- **What is it then that causes the PC aging ? → answer still unclear**

[Results and conclusions from Jeff deFazio, 2016]

# Outlook

- Further investigations to understand the aging process
  - PHOTONIS XP85112 (9001223 and 9001332) are unique MCP-PMTs with an aged and an unaged half of the photo cathode (PC)
    - At PHOTONIS with non-destructive investigations of the PC
    - Maybe X-ray diffraction measurement of the PC
  - Identify the mass of the feedback ions with afterpulsing spectra
    - Compare different types of MCP-PMTs (e.g., 10  $\mu\text{m}$ , 25  $\mu\text{m}$ , ALD, non-ALD)
- Accelerate aging and lifetime measurements
  - Saturation effects: aging speed depends on photon rate and intensity
    - M.Yu. Barnyakov and A.V. Mironov, 2011 JINST 6 C12026
  - Simultaneous current measurement at cathode and anode requires one potential-free picoammeter
- Setup semi-automatic quality control for MCP-PMT mass delivery

# Summary

- New high-granularity 2" Hamamatsu MCP-PMT
  - Good properties, but some parameters need more tuning
  - Long tails in position distributions not understood
  - Possibility to measure Lorentz shift in B-field
- **Tremendous lifetime increase of latest MCP-PMTs** due to recent design improvements
  - **Application of ALD technique (> x50 lifetime improvement)**
  - **Huge step forward !**
  - **But: aging mechanism is not explained by simple work function arguments**
- Equipping the PANDA DIRCs and other high rate detectors with MCP-PMTs is feasible now
