

# The MATRIX element method in HEP

Lorenzo Bianchini  
ETH Zürich

# A general problem

*How can we maximally extract information  
(on physical parameters  $\theta$ ) from an HEP event  $\mathbf{Y}$ ?*

- In HEP,  $\dim(\mathbf{Y}) \gg 1^*$ 
  - ▶ need data reduction with no loss of information
    - find a statistic  $T = T(\mathbf{Y})$  that is *sufficient* for  $\theta$
  - ▶ “The Maximum Likelihood estimator is asymptotically sufficient for  $\theta$ ”
- How to derive the likelihood of an event ?
  - ▶ if  $\dim(\mathbf{Y})$  small: templates using MC simulation
  - ▶ otherwise:
    - machine learning \*\*
    - analytical approach

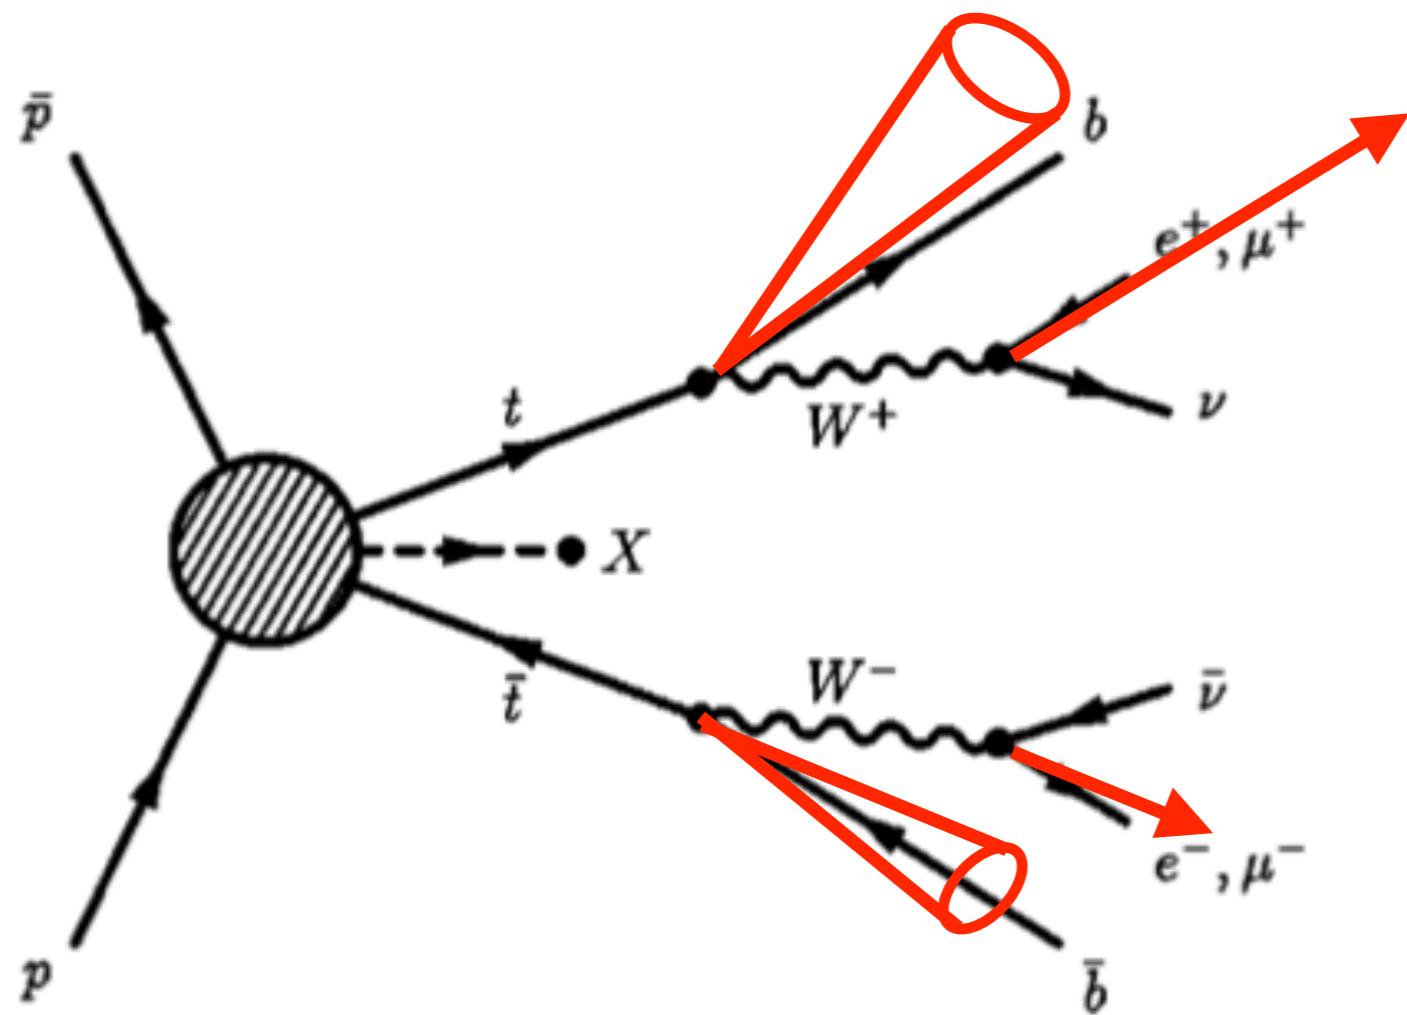

(\*) Vincenzo's talk

- ▶ multi-channel processes:

$$p(\vec{y}; \theta) = \lambda_S(\theta) p_S(\vec{y}; \theta) + \sum_j \lambda_B j p_B j(\vec{y})$$

# General formulation of the MEM

$$\text{Prob}\{\vec{y} \in [\vec{y}_0, \vec{y}_0 + d\vec{y}] \mid S, \theta\} = p_S(\vec{y}_0; \theta) d\vec{y} \quad \int_A p_S(\vec{y}; \theta) d\vec{y} = 1$$

- ▶ (normalised) differential cross section:

$$p_S(\vec{y}; \theta) = \frac{1}{\sigma_S(\theta)} \frac{d\sigma_S}{d\vec{y}}(\vec{y}; \theta)$$

$$d\sigma_S(\vec{y}; \theta) = \left[ \int d\Phi(\vec{x}) dx_a dx_b \sum_{i,j} \frac{f_i(x_a) f_j(x_b)}{(1 + \delta_{ij}) x_a x_b s} |\mathcal{M}_S(\vec{x}, \theta)|^2 W(\vec{y}, \vec{x}; \theta) \right] d\vec{y}$$

- ▶ multi-channel processes:

$$p(\vec{y}; \theta) = \lambda_S(\theta) p_S(\vec{y}; \theta) + \sum_j \lambda_B j p_B j(\vec{y})$$

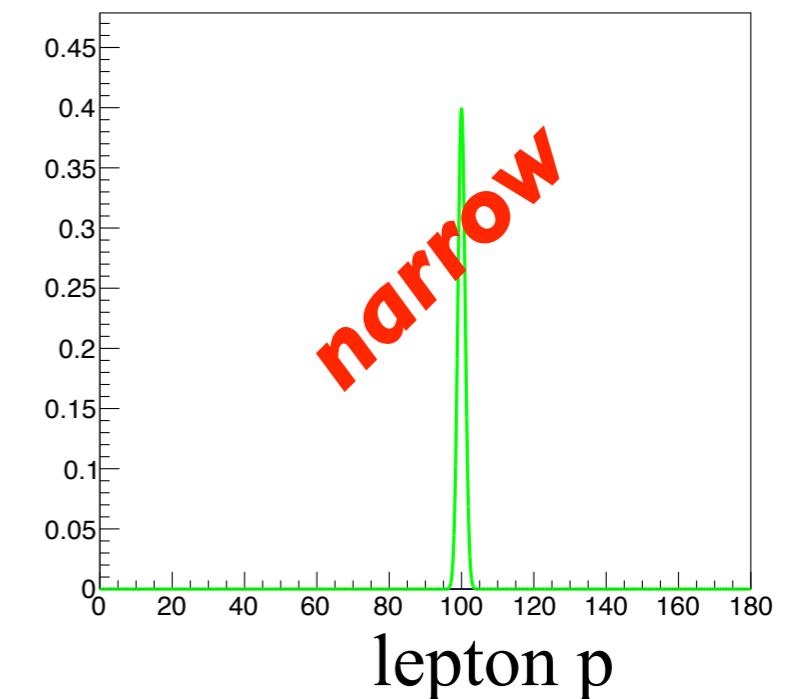

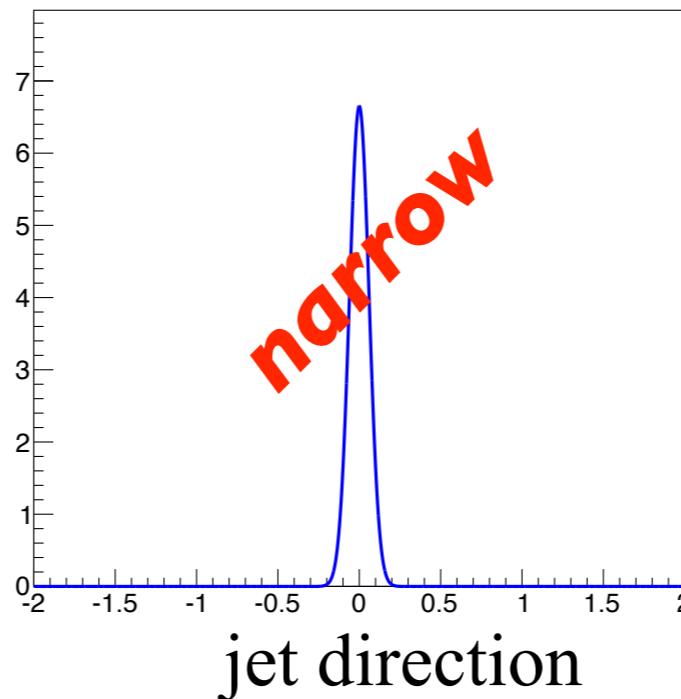

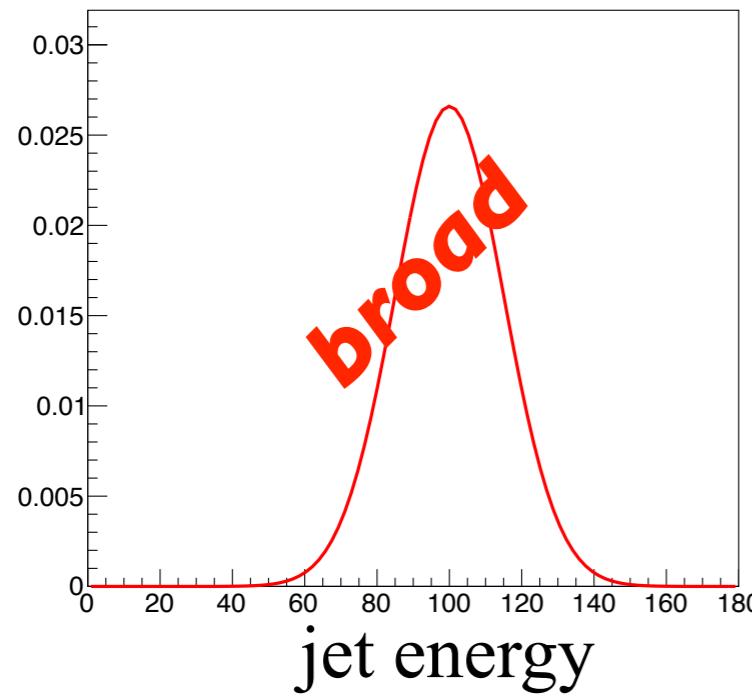

- ▶ sample likelihood:

$$\mathcal{L}(\vec{y}; \theta) = \left[ \prod_{i=1}^N p(\vec{y}_i; \theta) \right] \frac{e^{-\mathcal{N}(\theta)} \mathcal{N}(\theta)^N}{N!}$$

# Transfer function

- Factorized
  - ▶ normalisation condition
  - ▶ broad vs narrow:

$$W(\vec{y}, \vec{x}) \approx \prod_i W(y_i, x_i)$$

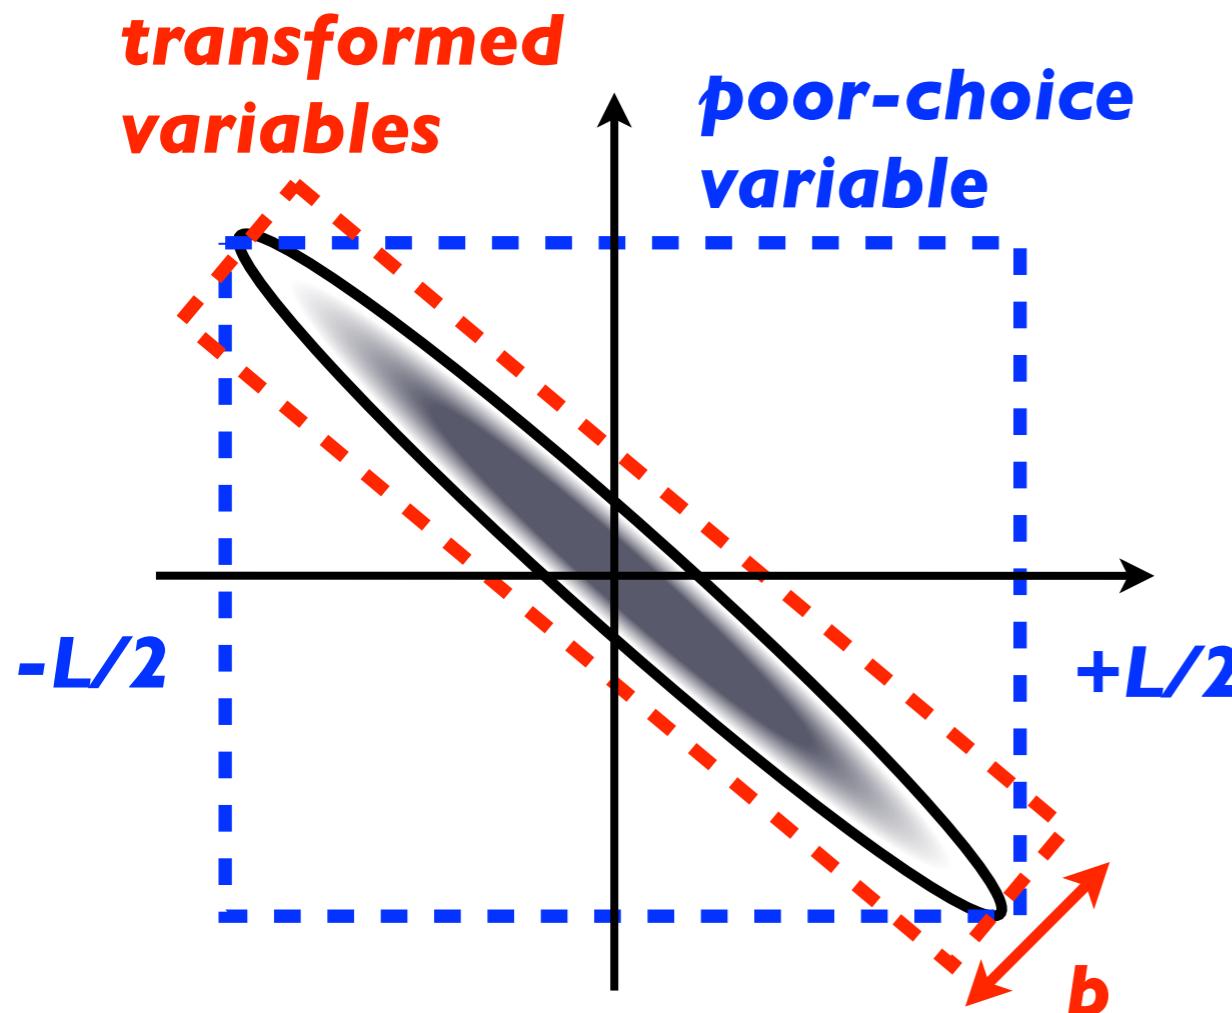

- Particle  $\Leftrightarrow$  detector association not always univocal !!!
  - ▶ need to permute all possible associations and sum them up

# Variable transformation

- Integrand often features peaks
  - ▶ narrow transfer functions
  - ▶ propagators
  - ▶ 4-momentum conservation

$$\frac{1}{(s^2 - M^2)^2 + \Gamma^2 M^2} \rightarrow \frac{\pi}{M\Gamma} \delta(s^2 - M^2)$$

$$d\Phi(\vec{x}) = (2\pi)^4 \delta(x_a P_a + x_b P_b - \sum_i p_i) \left[ \prod_i \frac{d^3 \vec{p}_i}{(2\pi)^3 2E_i} \right]$$

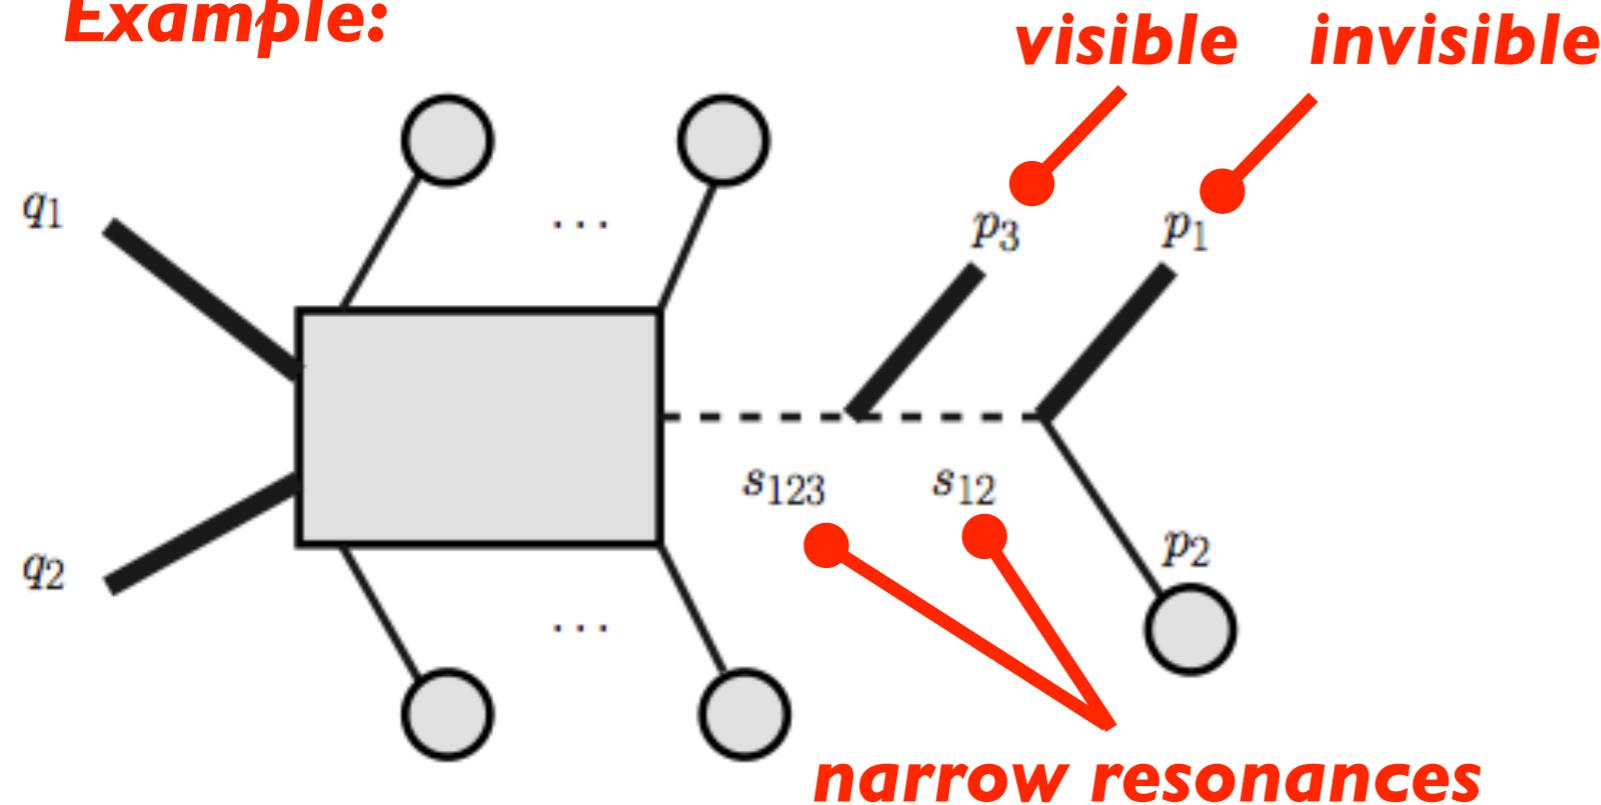

- Align integration variables along peaking directions

# Automation of the MEM\*

Variable alignment can be automated (MadWeight, BEM)

- ▶ variable transformation for each topology
- ▶ solve system of equations
- ▶ determine Jacobian factor

**Example:**

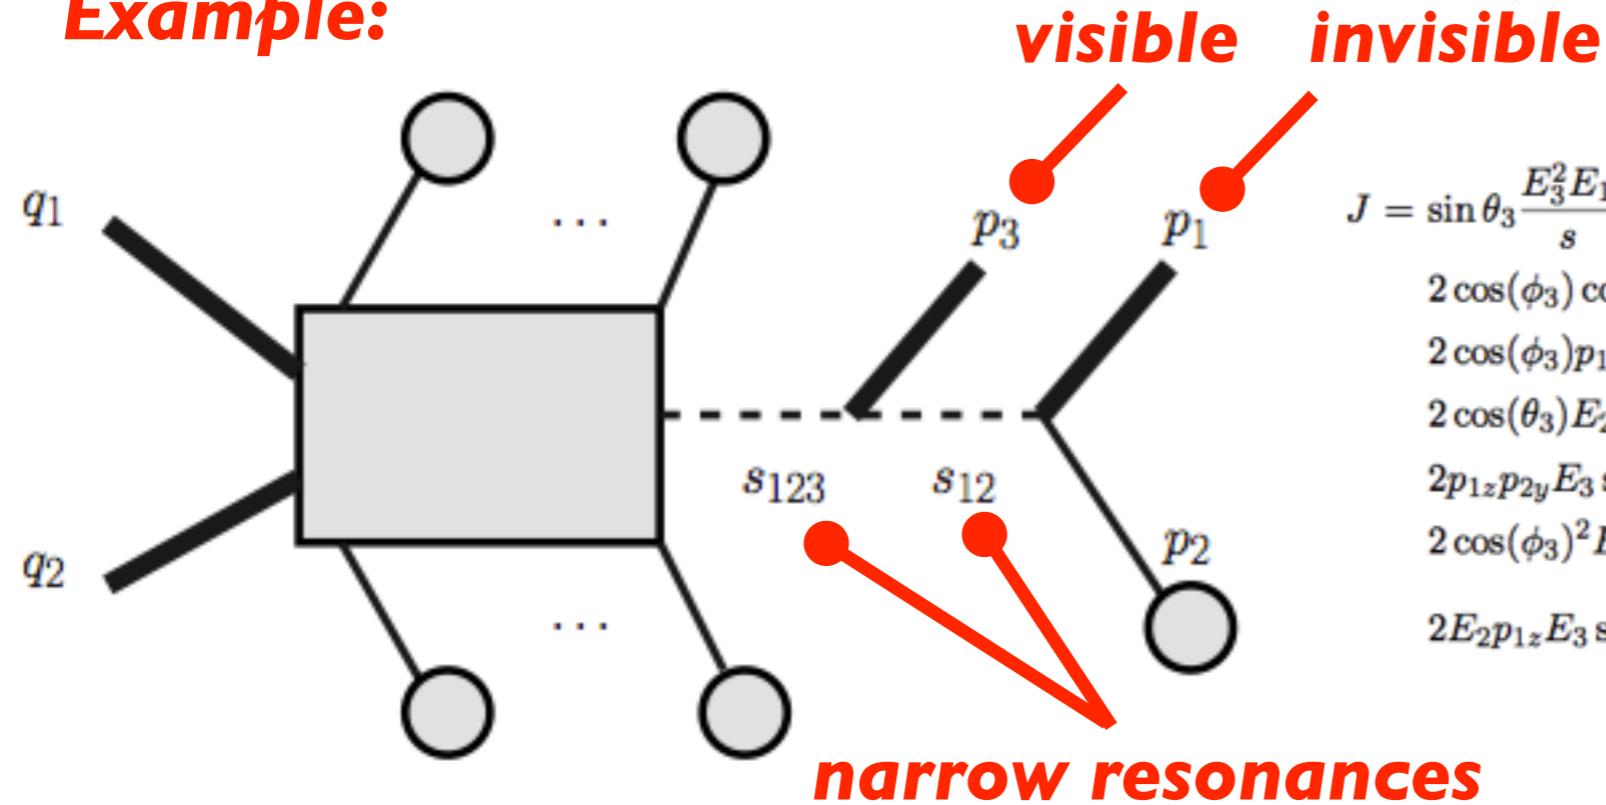

# Automation of the MEM\*

Variable alignment can be automated (MadWeight, BEM)

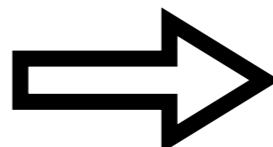

- ▶ variable transformation for each topology
- ▶ solve system of equations
- ▶ determine Jacobian factor

**Example:**

$$J = \sin \theta_3 \frac{E_3^2 E_1}{s} \left| \chi E_2 p_{1z} - \chi E_1 p_{2z} - 2 \cos(\phi_3) \cos(\theta_3) E_2 p_{1x} E_3 \sin(\theta_3) + 2 \cos(\phi_3) \cos(\theta_3) E_1 p_{2x} E_3 \sin(\theta_3) - 2 \cos(\phi_3) p_{1z} p_{2x} E_3 \sin(\theta_3) + 2 \cos(\phi_3) p_{1x} p_{2z} E_3 \sin(\theta_3) - 2 \cos(\theta_3) E_2 p_{1y} E_3 \sin(\phi_3) \sin(\theta_3) + 2 \cos(\theta_3) E_1 p_{2y} E_3 \sin(\phi_3) \sin(\theta_3) - 2 p_{1z} p_{2y} E_3 \sin(\phi_3) \sin(\theta_3) + 2 p_{1y} p_{2z} E_3 \sin(\phi_3) \sin(\theta_3) + 2 \cos(\phi_3)^2 E_2 p_{1z} E_3 \sin(\theta_3)^2 - 2 \cos(\phi_3)^2 E_1 p_{2z} E_3 \sin(\theta_3)^2 + 2 E_2 p_{1z} E_3 \sin(\phi_3)^2 \sin(\theta_3)^2 - 2 E_1 p_{2z} E_3 \sin(\phi_3)^2 \sin(\theta_3)^2 \right|^{-1},$$

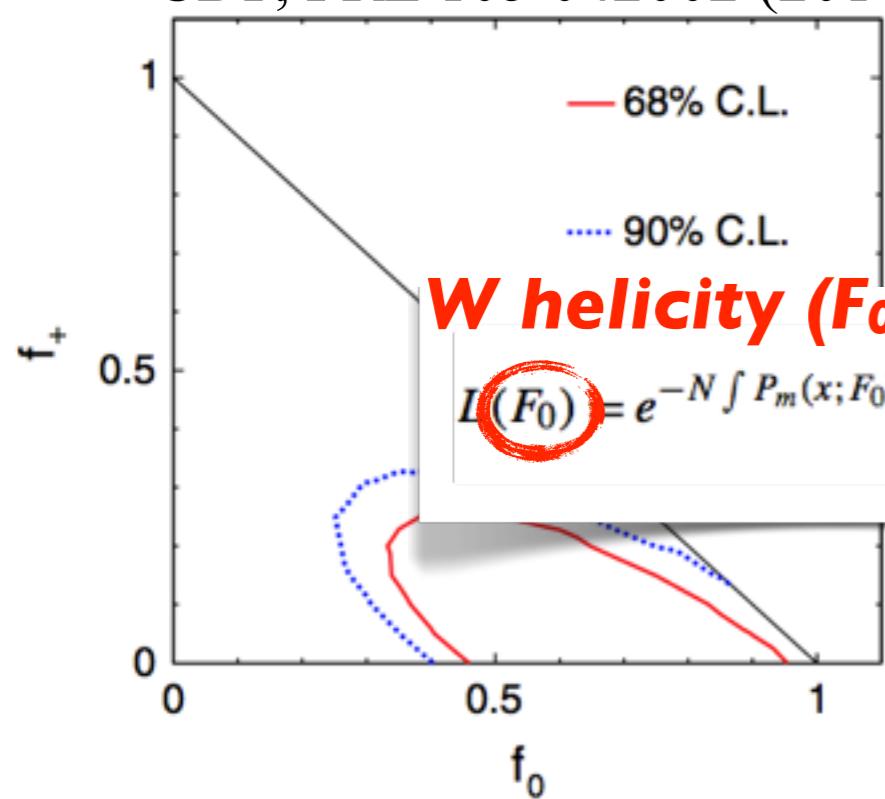

$$dq_1 dq_2 \frac{d^3 p_1}{(2\pi)^3 2E_1} \frac{d^3 p_3}{(2\pi)^3 2E_3} (2\pi)^4 \delta^4 (P_{\text{in}} - P_{\text{fin}})$$

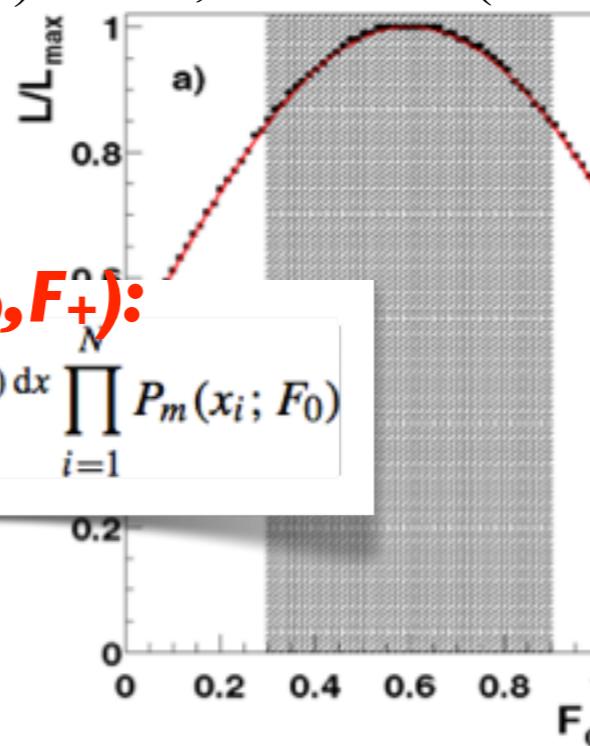

$$\frac{1}{16\pi^2 E_1 E_3} d\phi_3 d\theta_3 ds_{12} ds_{123} \times J$$

# MEM for point estimation

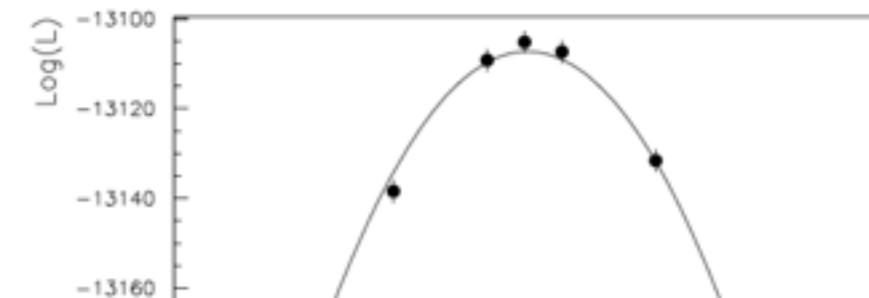

CDF, PRL 105 042002 (2010)

D0, PLB 617 (2005) 1

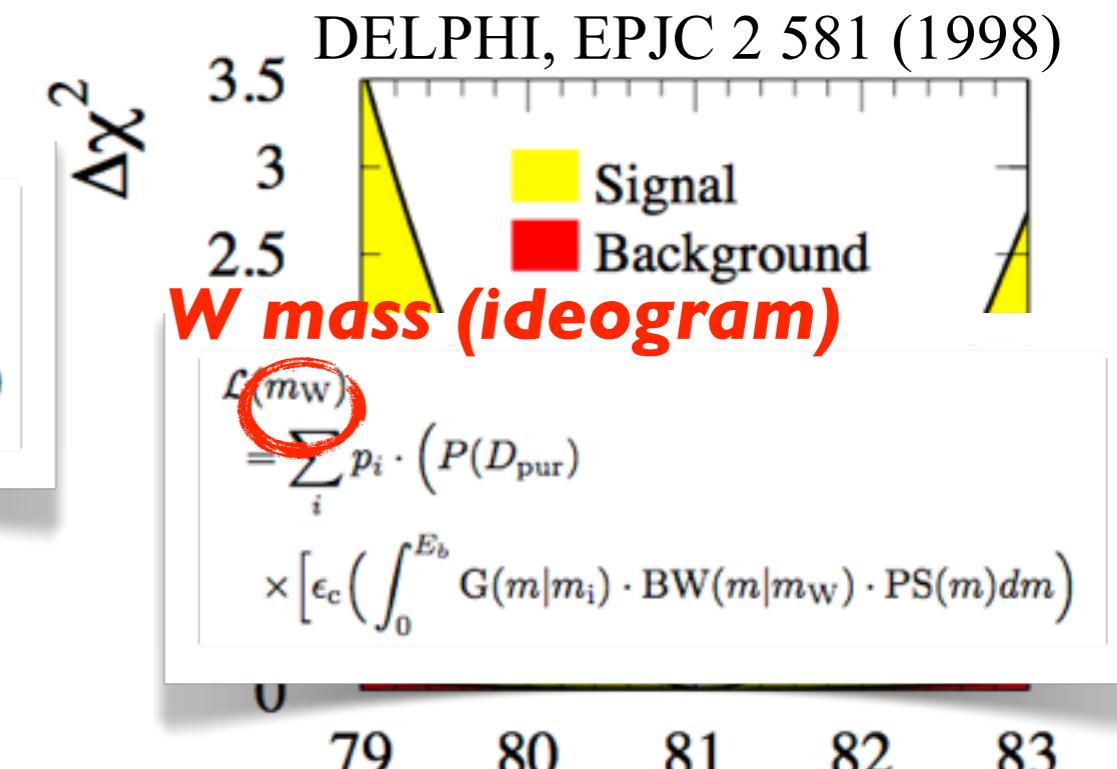

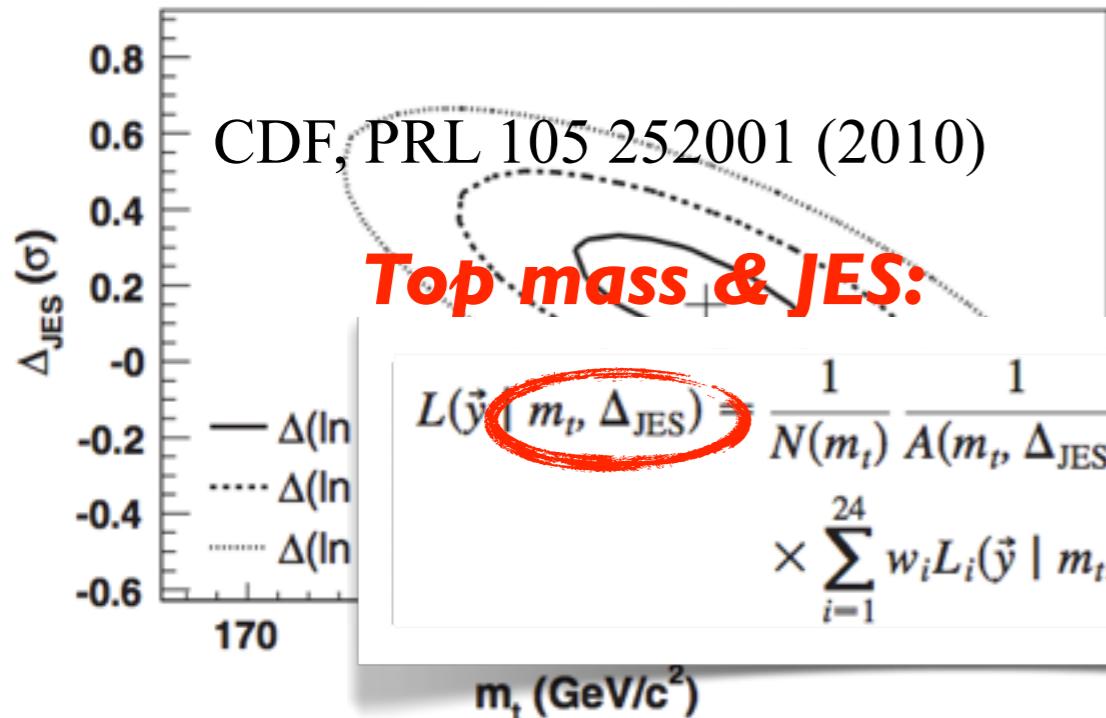

Berends et al. PRL B417 (1998) 385

$$p(\{\phi_i\}) M_W = \frac{1}{\sigma_{tot}} \frac{d\sigma}{dE_\ell d\Omega_\ell d\Omega_{q_1} d\Omega_{q_2}}$$

$e^+e^- \rightarrow W^+W^-$

F. Canelli, FERMILAB-THESIS-2003-22 (2003)

# An efficient estimator

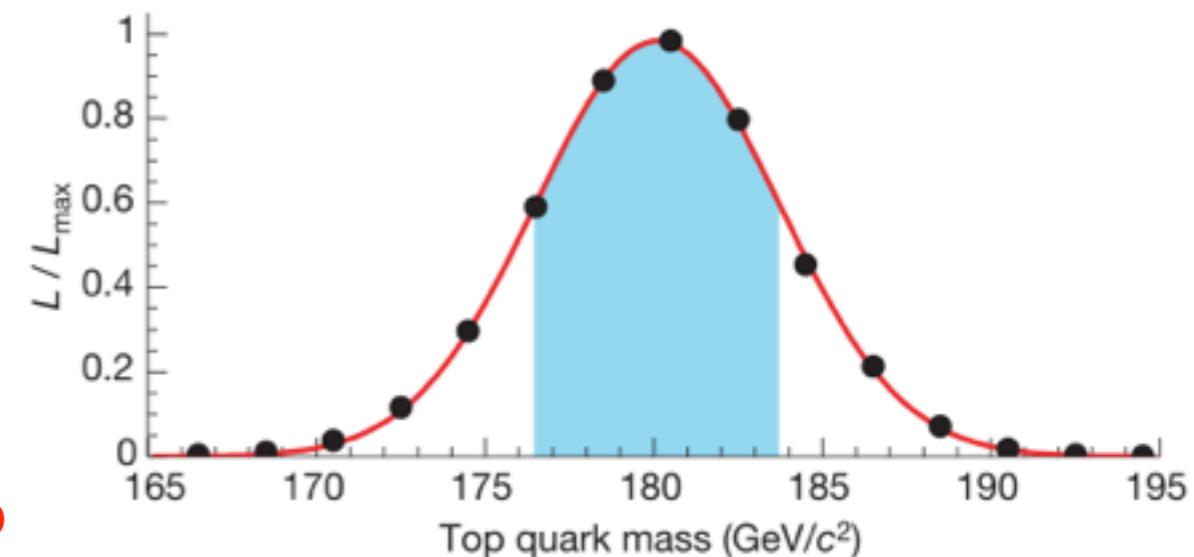

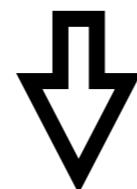

D0, PRD 58 052001 (1998)

“ We determine the top quark mass  $m_t$ , using  $t\bar{t}$  pairs produced in the DØ detector by  $\sqrt{s}=1.8 \text{ TeV } pp$  collisions in a  $125 \text{ pb}^{-1}$  exposure at the Fermilab Tevatron. We make a two constraint fit to  $m_t$  in  $t\bar{t} \rightarrow bW^+bW^-$  final states with one  $W$  boson decaying to  $qq$  and the other to  $e\nu$  or  $\mu\nu$ . Likelihood fits to the data yield  $m_t(l+\text{jets}) = 173.3 \pm 5.6 \text{ (stat)} \pm 5.5 \text{ (syst) GeV}/c^2$ . When this result is combined with an analysis ”

D0, Nature 479 (2004)

“ smaller, and discussed in detail elsewhere<sup>21,22</sup>. It should be noted that the new mass measurement method provides a significant (about 40%, from  $\pm 5.5$  to  $\pm 3.9 \text{ GeV}/c^2$ ) reduction in systematic uncertainty, which is ultimately dominated by the measurement of jet energies. For details on the new analysis, see the Methods.

The final result is  $M_t = 180.1 \pm 3.6 \text{ (stat)} \pm 3.9 \text{ (syst) GeV}/c^2$ . The improvement in statistical uncertainty over our previous measurement is equivalent to collecting a factor of 2.4 as much data. Combining the statistical and systematic uncertainties in ”

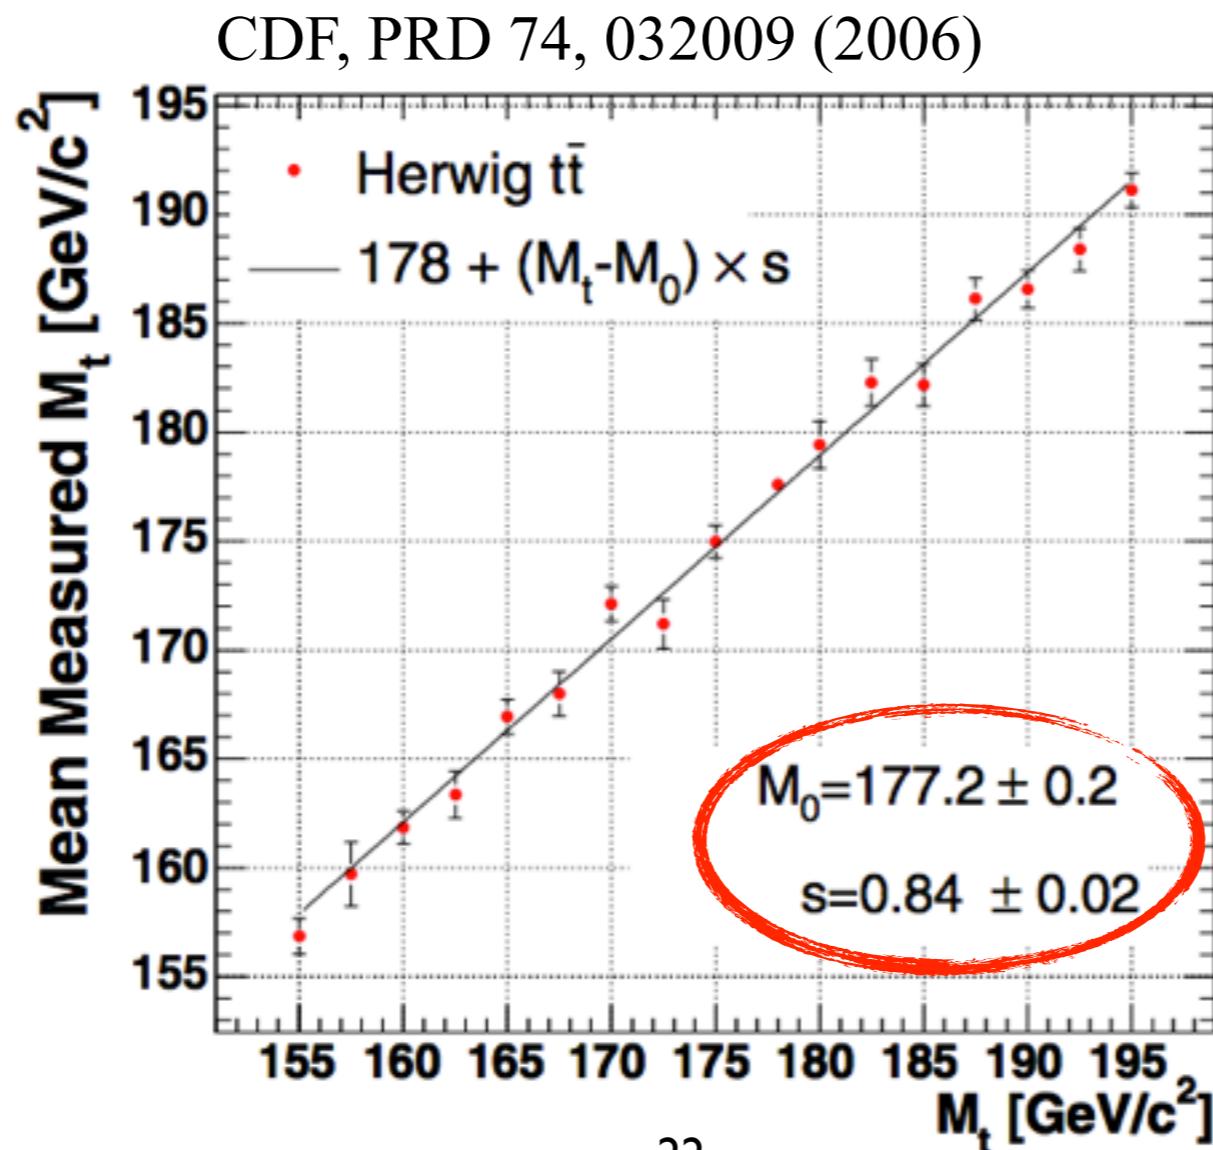

Main virtues of the MEM evident here:

- ▶ optimise statistical power of available data
- ▶ systematic uncertainties (nuisance parameters) calculated event-by-event
  - each event contributes with optimal weight!

# Linearity

## Linearity test using MC simulation

- ▶ check for bias due to model approximations
- ▶ determine calibration function
  - approximations in MEM don't hamper its applicability, just make it less optimal!

# MEM for hypothesis testing

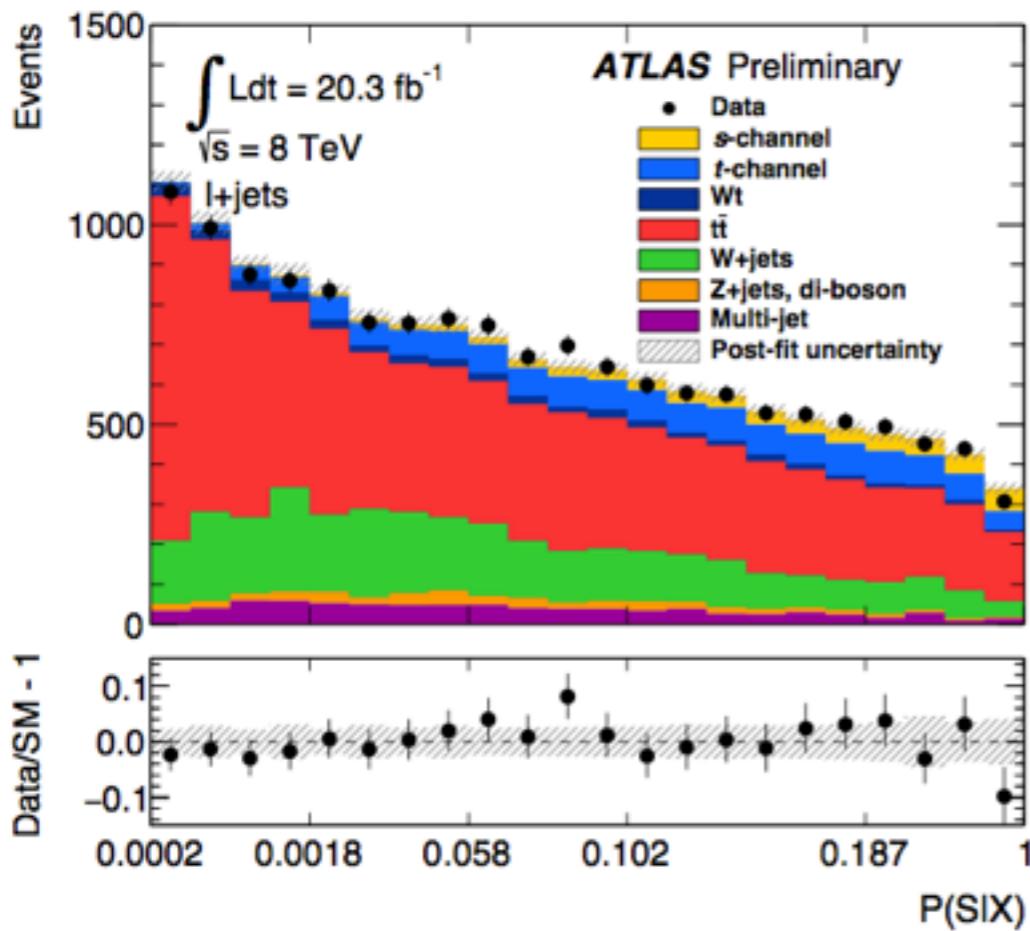

- Ratio of MEM probability densities is a powerful test statistic
  - ▶ optimal properties (largest power at fixed error) L. Neyman, Phil. Trans. Royal Soc. London 236 (1937) 333

$$LR = \frac{\lambda_S p_S}{\sum_j \lambda_{B_j} p_{B_j}}$$

or

$$\frac{1}{1 + LR} \in [0, 1]$$

ATLAS-CONF-2015-047

- No need of training sample
  - ▶ relevant for searches in rare topologies

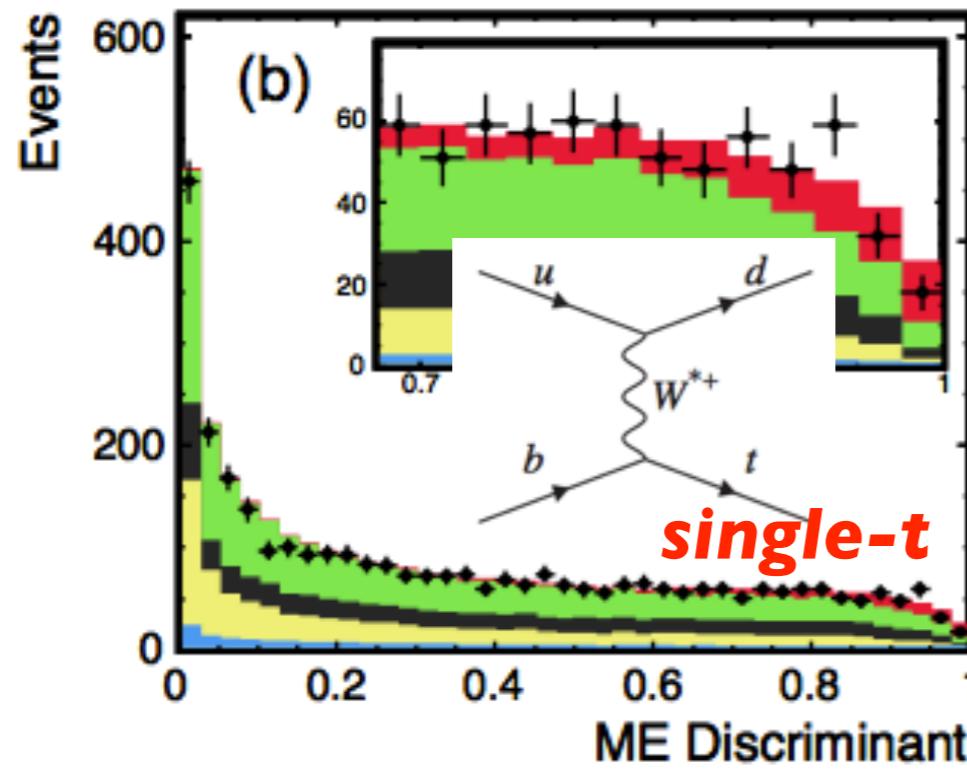

“

In contrast to the aforementioned BDT-based analysis [11], the signal extraction in this analysis is based on the Matrix Element (ME) Method [18, 19]. The used data set is still the same, while some of the simulation samples are replaced by enhanced ones which reduces the uncertainty due to the simulation statistics and gives a better description of the data. Furthermore, updated calibrations for the 2012 data are used, resulting in a reduction of systematic uncertainties. The event selection is improved by adding a veto on di-leptonic events which leads to a significant suppression of the background for top-quark pair ( $t\bar{t}$ ) production (c. f. Sec. 5). The combination of all these measures results in a significant improvement in the sensitivity to the  $s$ -channel process. Approximately half of this improvement can be attributed to the change in method from BDT to ME. In particular, the BDT technique applied to this analysis is limited by the sample sizes available for the training, while the ME approach is not sensitive to this limitation.

## Example of MEM implementation for a ttH search (~3k lines)

- ▶ requirements: C++ compiler, ROOT, LHAPDF
- ▶ features:
  - factorisation of MEM can be easily implemented in object-oriented languages
  - channel-specific optimisations

```

int main(){

    // create a new instance of the class
    MEMCalculator* my_mem_example = new MEMCalculator();

    // add observables as members of the class
    RecoObject j1;
    j1.SetPtEtaPhiM( /* ... */ );
    j1.AddObservable( /* ... */ );
    j1.AddTransferFunction( tf );
    my_mem_example->push_back_object( &j1 );
    /* ... */

    p_s = my_mem_example->run( Hypothesis::TTH, {Particle::qbar1} );
    p_b = my_mem_example->run( Hypothesis::TTBB, {Particle::qbar1} );

    double mem_discriminant = p_s / (p_s + p_b)
}

```

A C++ **class**;  
**observables are class members**

**S or B,**  
**nonreconstructed**  
**particles, ...**

```

double MEMCalculator::run( /* ... */ ){
    // build integrand from Eval() method of this class
    Math::Functor toIntegrate(this, &MEMCalculator::Eval, npar);

    // GSL integrator, attach toIntegrate() to it
    GSLMCIntegrator* vegas = new GSLMCIntegrator(
        IntegrationMultiDim::kVEGAS,
        abs, rel, n_max_calls);

    // attach the integrand to the integrator
    vegas->SetFunction(toIntegrate);

    // integration ranges: npar = # of integration variables
    // need a routine to determine the integral domain
    double xL[npar], xU[npar];
    set_integration_range(xL, xU);

    // that's it, just call Integral()!!!
    return vegas->Integral(xL,xU);
    /* ... */
}

```

**Eval() must  
return the  
integrand**

**GSL implementation  
of VEGAS**

**This function does  
what it says!**

```

double MEMCalculator::Eval(const double* x) const {
    // define a new phase-space point
    PhaseSpacePoint ps = create_PS(x);

    // calculate the integrand
    double p{1.0};

    p *= theory(ps);
    p *= transfer(ps);

    return p;
}

```

**double\* x =  
integration variables**

**Each VEGAS point “x”  
maps to a phase-space  
point “ps”  
This is process-specific**

$$\int d\Phi(\vec{x}) dx_a dx_b \sum_{i,j} \frac{f_i(x_a) f_j(x_b)}{(1 + \delta_{ij}) x_a x_b s} |\mathcal{M}_S(\vec{x}, \theta)|^2 W(\vec{y}, \vec{x}; \theta)$$

```

double MEMCalculator::Eval(const double* x) const {
    /* ... */
    PhaseSpacePoint ps = create_PS(x);
    /* ... */
}

```

```

PhaseSpacePoint MEMCalculator::create_PS( const double* x ) const {

    // deal with Particle::q1
    if( isMatched(Particle::q1) ){
        dir      = jets[ Particle::q1 ].p4().Vect().Unit();
    }
    else{
        dir.SetTheta( x[Variable::theta_q1] );
        dir.SetPhi   ( x[Variable::phi_q1] );
    }
    // E_q1 is one of the integration variables
    E_q1 = x[Variable::E_q1];
    /* ... */
}

```

***if a quark is matched to a jet:  
use jet direction***

***else:  
integrate over  
quark direction***

```

double MEMCalculator::Eval(const double* x) const {
    /* ... */
    p *= theory(ps);
    p *= transfer(ps);
    /* ... */
}

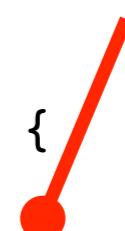

double MEMCalculator::theory(const PhaseSpacePoint& ps) const {
    // read particle 4-vector from the phase-space point
    LorentzVector q1 = ps.lv(Particle::q1);
    /* ... */

    m *= pdf( x1, x2 );
    m *= amplitude2( t, tx, b, bx );
    /* ... */
}

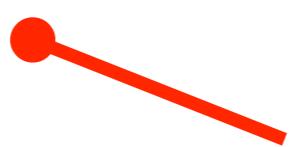

double MEMCalculator::transfer(const PhaseSpacePoint& ps) const {
    // loop over all quarks/leptons/neutrino
    for( PSMMap::const_iterator p = ps.begin() ; p != ps.end() ; ++p ){
        if( isJet( p ) ){
            w *= TMath::Gaus( jets[p]->E(), p->E(), 0.15*p->E() );
            /* ... */
        }
    }
    /* ... */
}

```

**Loop over all particles and evaluate  $W(x,y)$**

**Assume simple Gaussian resolution**

```

double MEMCalculator::theory(const PhaseSpace& ps) const {
    /* ... */
    m *= pdf( x1, x2 );
    m *= amplitude( t, tx, b, bx );
    /* ... */
}

double MEMCalculator::amplitude2( /* ... */ ) const {
    // Boost to "MEM frame"
    TVector3 boostPt( vSum.Px()/vSum.E(), vSum.Py()/vSum.E(), 0.0 );
    t.Boost( -boostPt ); tx.Boost( -boostPt ); h.Boost( -boostPt );

    /* ... */

    // interface to Fortran routine (OpenLoops)
    if( hypo==Hypothesis::TTH )
        pphtxcallme2born_(g1, g1, t, tx, b, bx, MTOP, MH);
    else:
        pptxbbxcallme2born_(g1, g1, t, tx, b, bx, MTOP);
    /* ... */
}

```

**Lorentz algebra  
(e.g. boost to MEM-frame)**

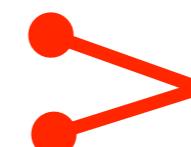

```

double MEMCalculator::pdf(const double& x1, const double& x2, const double& Q)
    const {
    /* ... */
    double f1 = LHAPDF::xfx(1, x1, Q, 0)/x1;
    double f2 = LHAPDF::xfx(1, x2, Q, 0)/x2;
    /* ... */
}

```

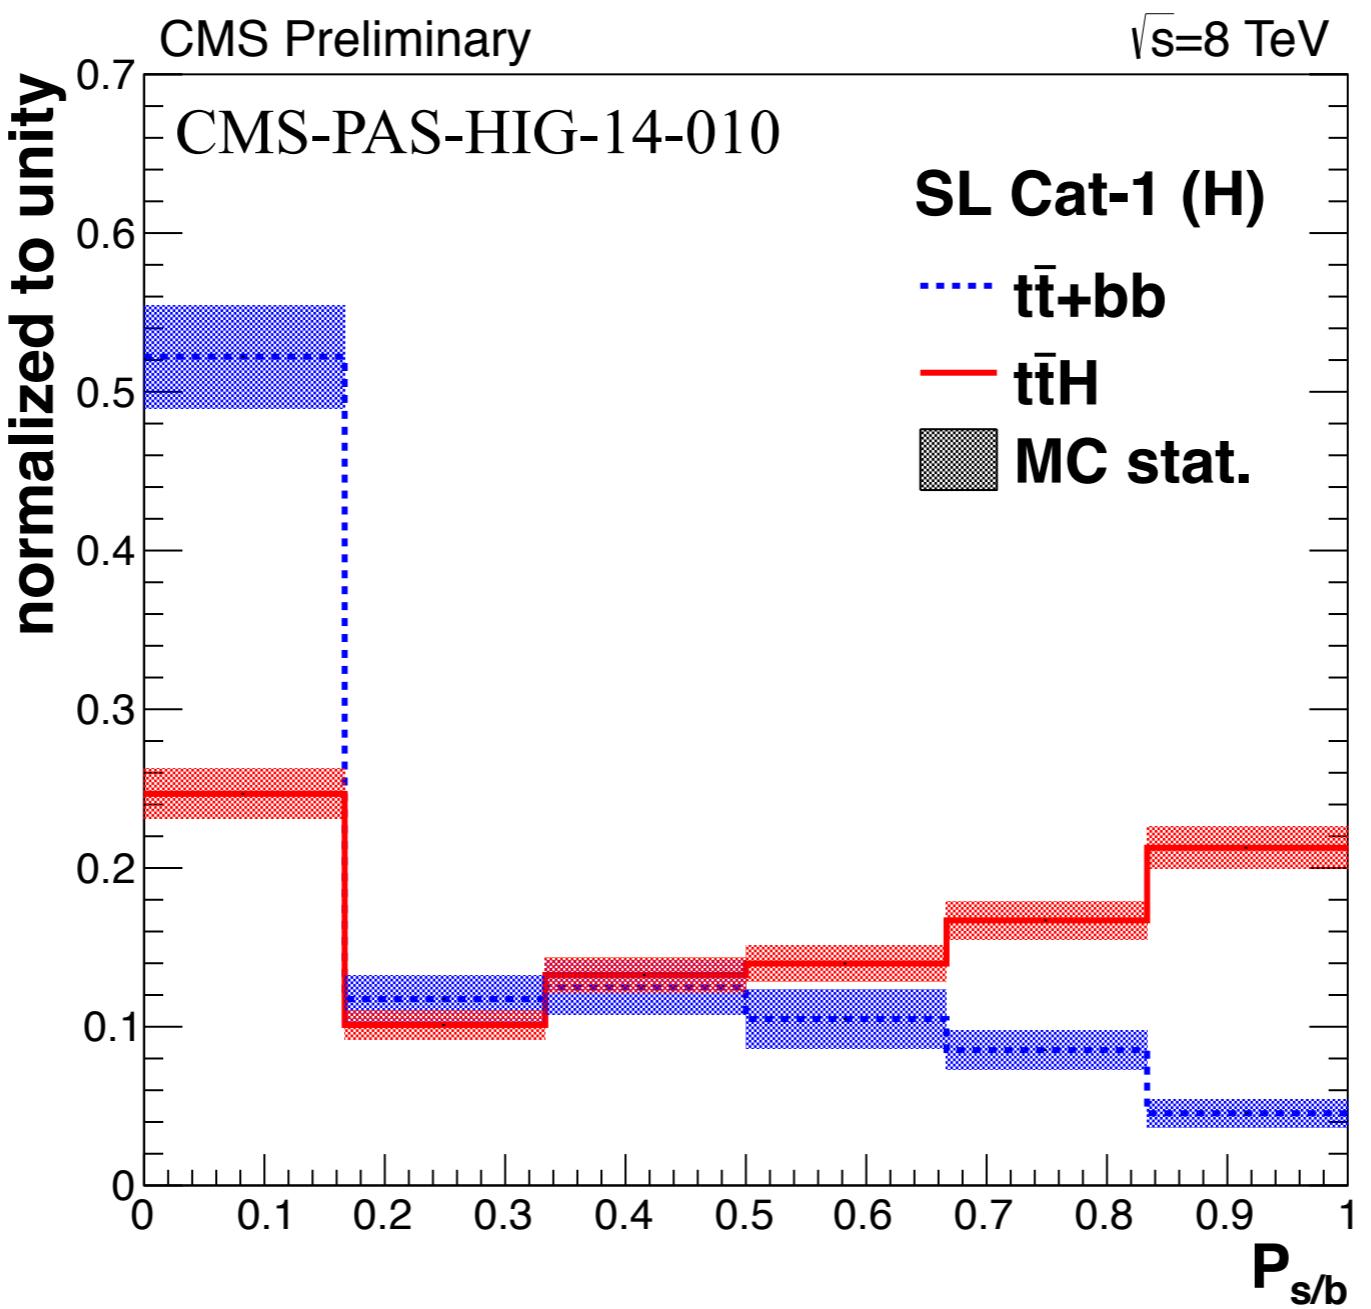

**Routines that compute the matrix element**

**Call to LHAPDF functions**

# Results

# Summary & outlook

- The MEM in High Energy Physics
  - ▶ compelling arguments behind the MEM approach for
    - parameter estimation
    - hypothesis testing
  - ▶ pioneered at Tevatron
    - top mass, W helicity, single-top measurements, Higgs searches
  - ▶ ramping up at LHC
    - single-top, ttH
- A field where technologies for data analysis matter
  - ▶ MEM remains a CPU-intensive business!
    - accelerating platforms (e.g. GPU)
    - distributed systems (e.g. MPI)

$$\mathcal{P}(\{o\}|m_t) \propto \int f(x)f(x)|\mathcal{M}|^2 p(\{o\}|\{v\}) \delta^4 d^{18}\{v\} dx dx,$$

(6)

“ Unfortunately this expression involves a multidimensional integral that has to be evaluated numerically and is complicated by the need to include initial and final state gluon radiation. Such higher order effects complicate the reconstruction of the top quark mass substantially and cannot be neglected. We therefore do not attempt to compute the exact probability density given in Eq. (6). Rather, we construct simpler weights that retain sensitivity to the value of the top quark mass but can be evaluated with the available computing resources. We calibrate the effect of the simplifi- ”

# Summary & outlook

A field where ML can have some complementarity

- ▶ higher-order predictions difficult to integrate into the MEM
  - LO vs NLO, parton shower, transfer function

# Summary & outlook

A field where ML can have some complementarity

- ▶ higher-order predictions difficult to integrate into the MEM
  - LO vs NLO, parton shower, transfer function
- ▶ ML can help where MEM falls short
  - several examples already exist
- ▶ squeezing every bit of information out of LHC data is our mandate!

# A kinematic fit?

Consider e.g. a kinematic fit

- ▶ jet  $\leftrightarrow$  quark assignment based on minimum  $\chi^2$
- ▶ works for fully-reconstructed events
- ▶ matching efficiency is low!

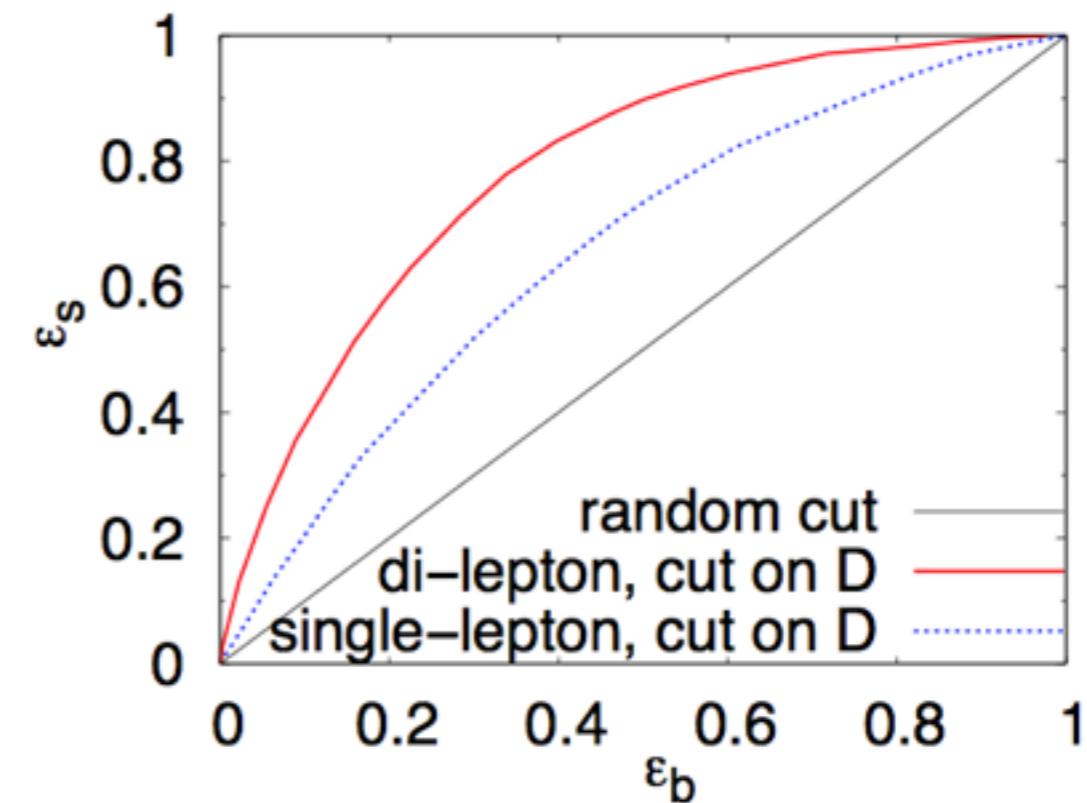

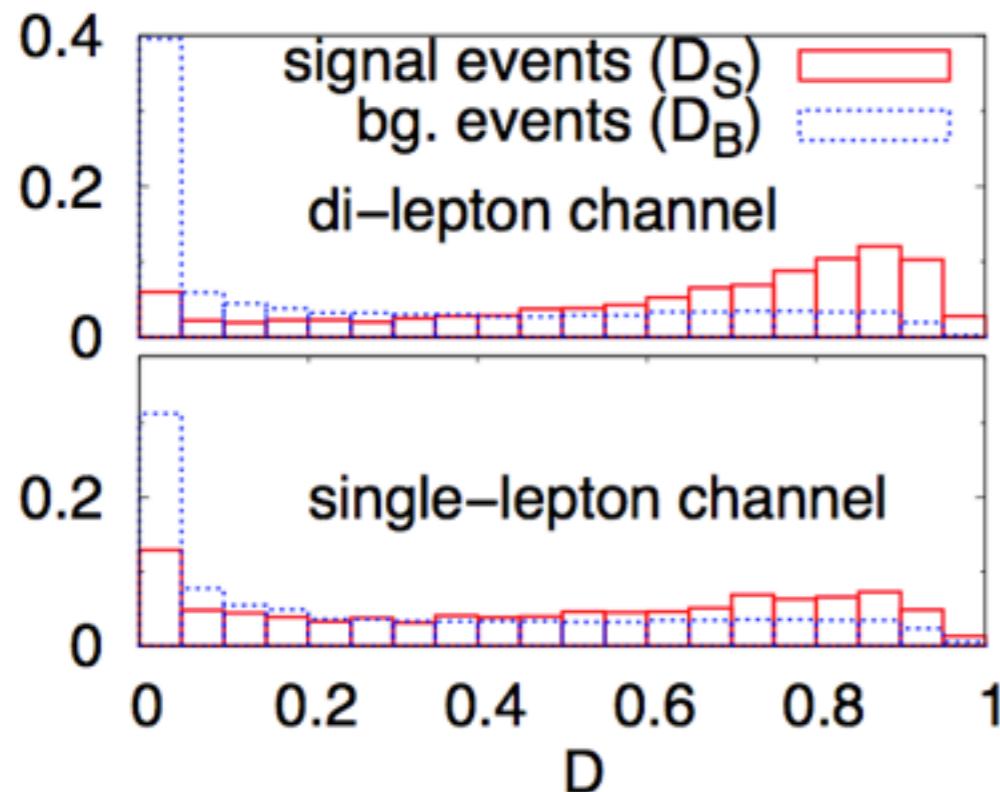

$\Rightarrow$  “combinatorial background”  
sculpted around  $m_H$

$\Rightarrow$  background shape  $\sim$ degenerate  
(poor separation)

# A possible analysis strategy

- Need a multi-dimensional analysis of particle kinematics
- MEM ideally suited for the task
  - ▶ maximise separation against ttbb
  - ▶ address combinatorial self-background
- Proof of principle worked out on 14 TeV simulation
  - ▶ likelihood analysis to  $D_i = \frac{P(\mathbf{x}_i|S)}{P(\mathbf{x}_i|S) + P(\mathbf{x}_i|B)}$  discriminant

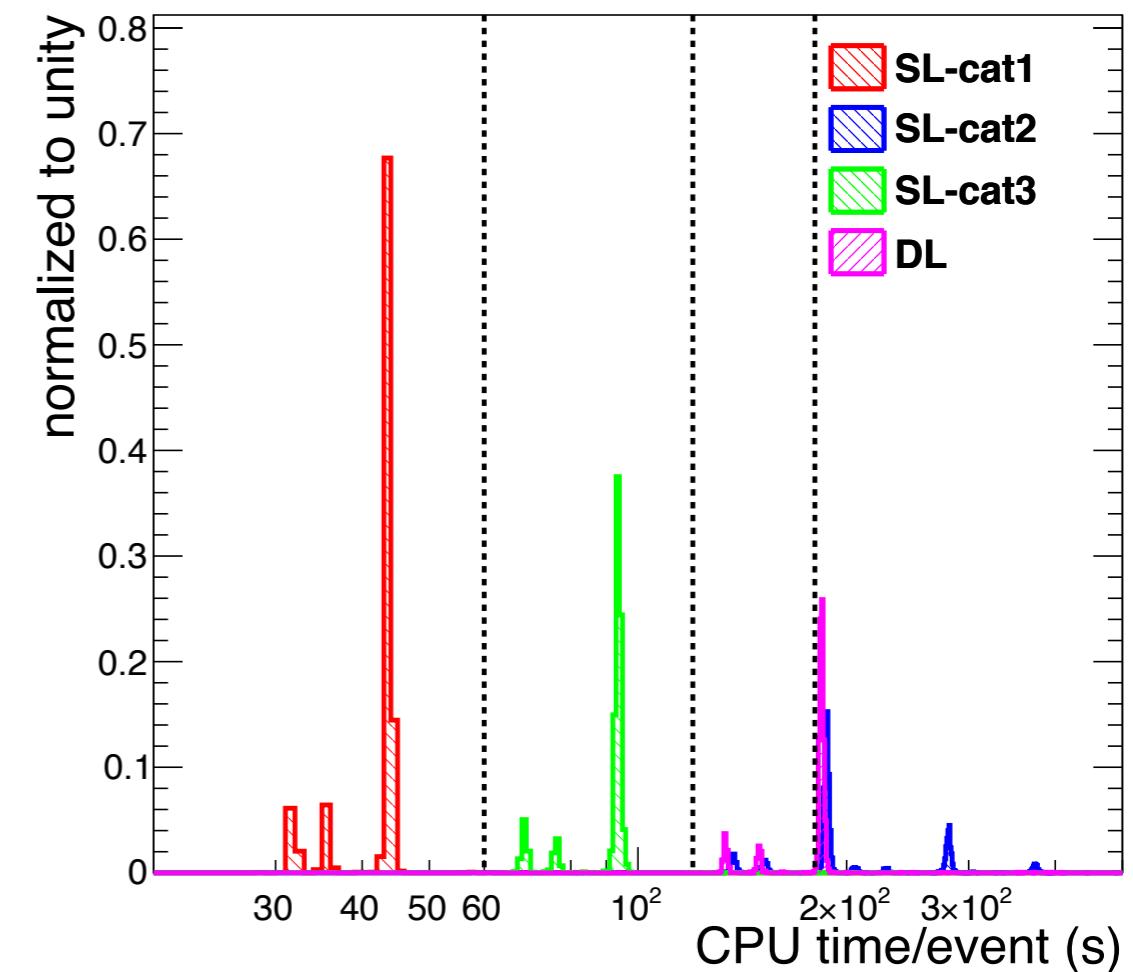

# FAQ: is CPU time an issue ?

Not really; compromise between **performance** and **timing**:

- ▶ run only on the good “events”
- ▶ filter-out permutations using b tagging ( $6! \rightarrow 4!$ )
- ▶ test one background hypothesis only
  - optimize separation against tt+bb
- ▶ parallelize (by event) as much as possible
- ▶ neglect spin/correlations
- ▶ JEC/JER systematics: bookkeep VEGAS grid result from “nominal” for faster evaluation
- ▶ ...

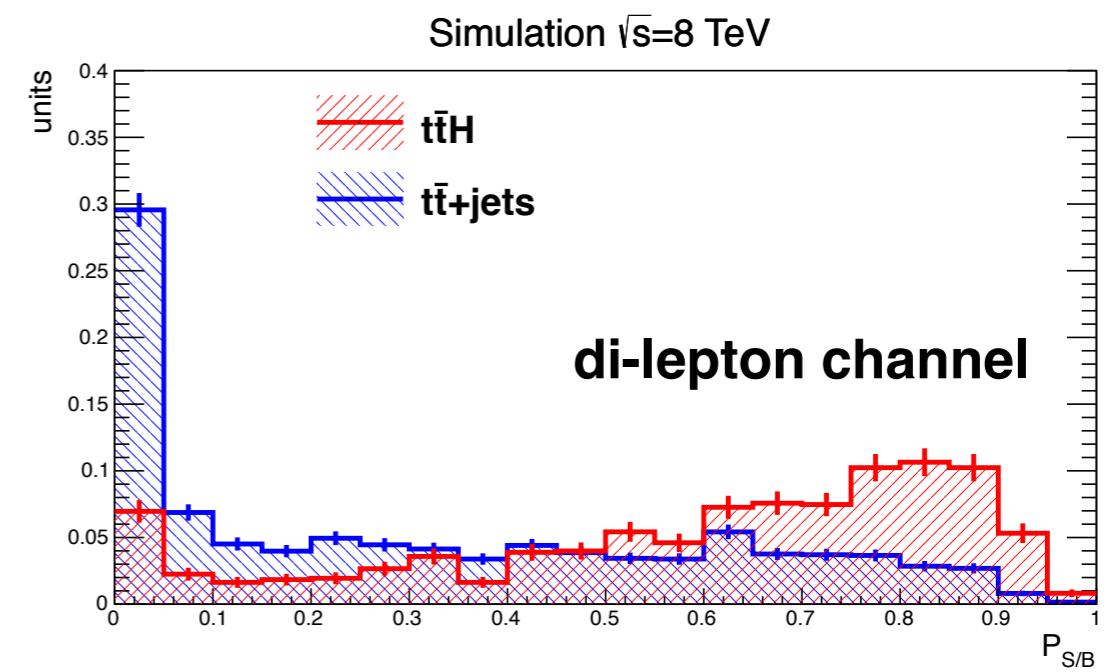

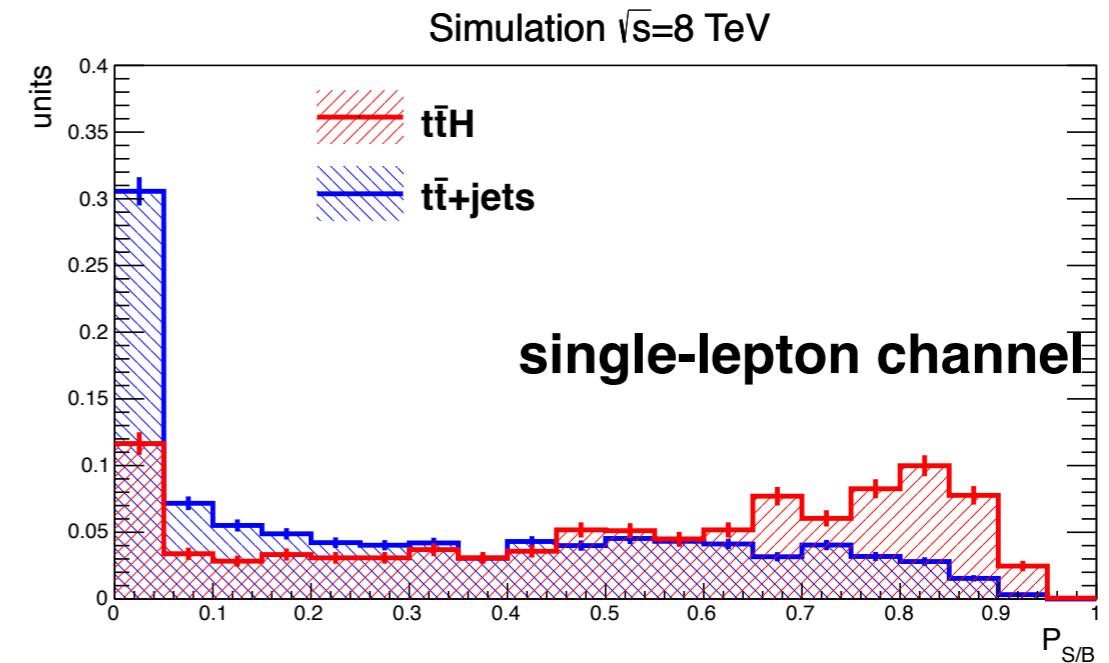

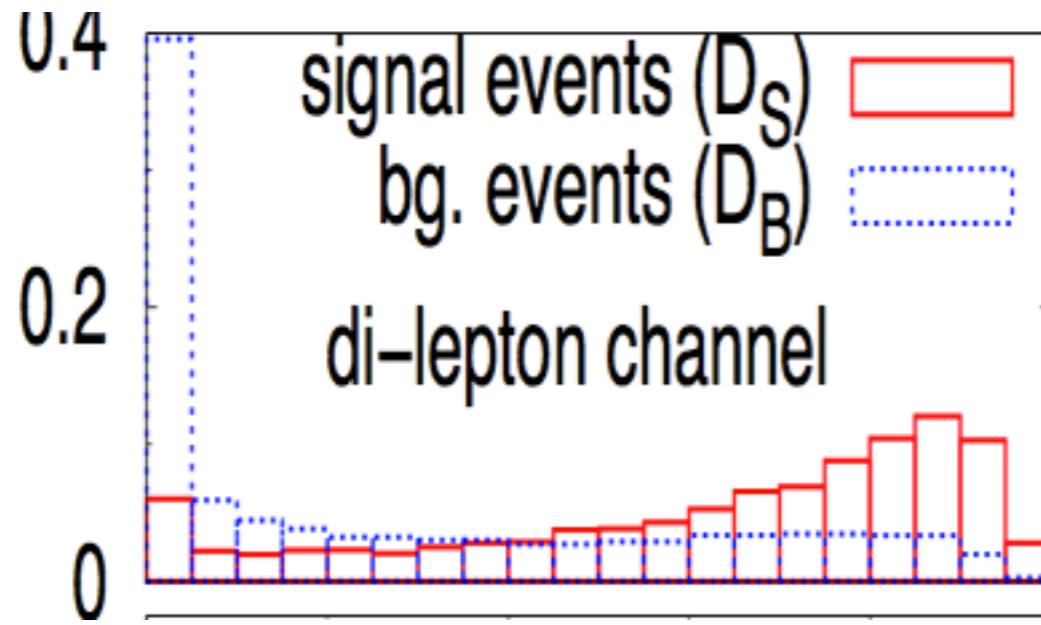

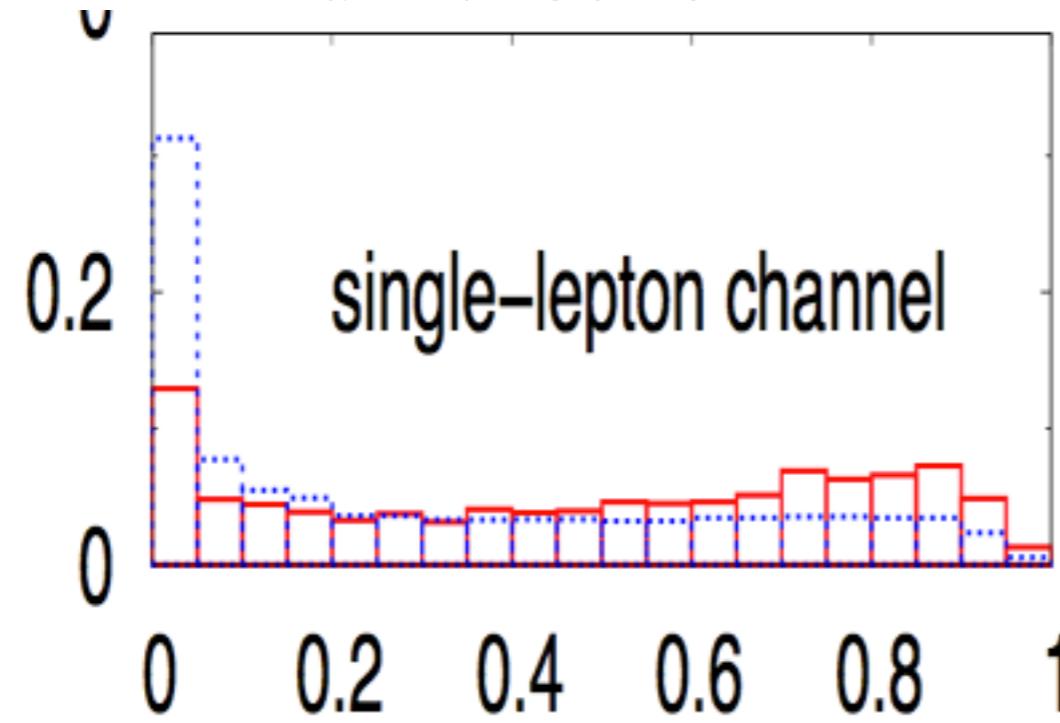

CMS Simulation  $\sqrt{s}=8$  TeV

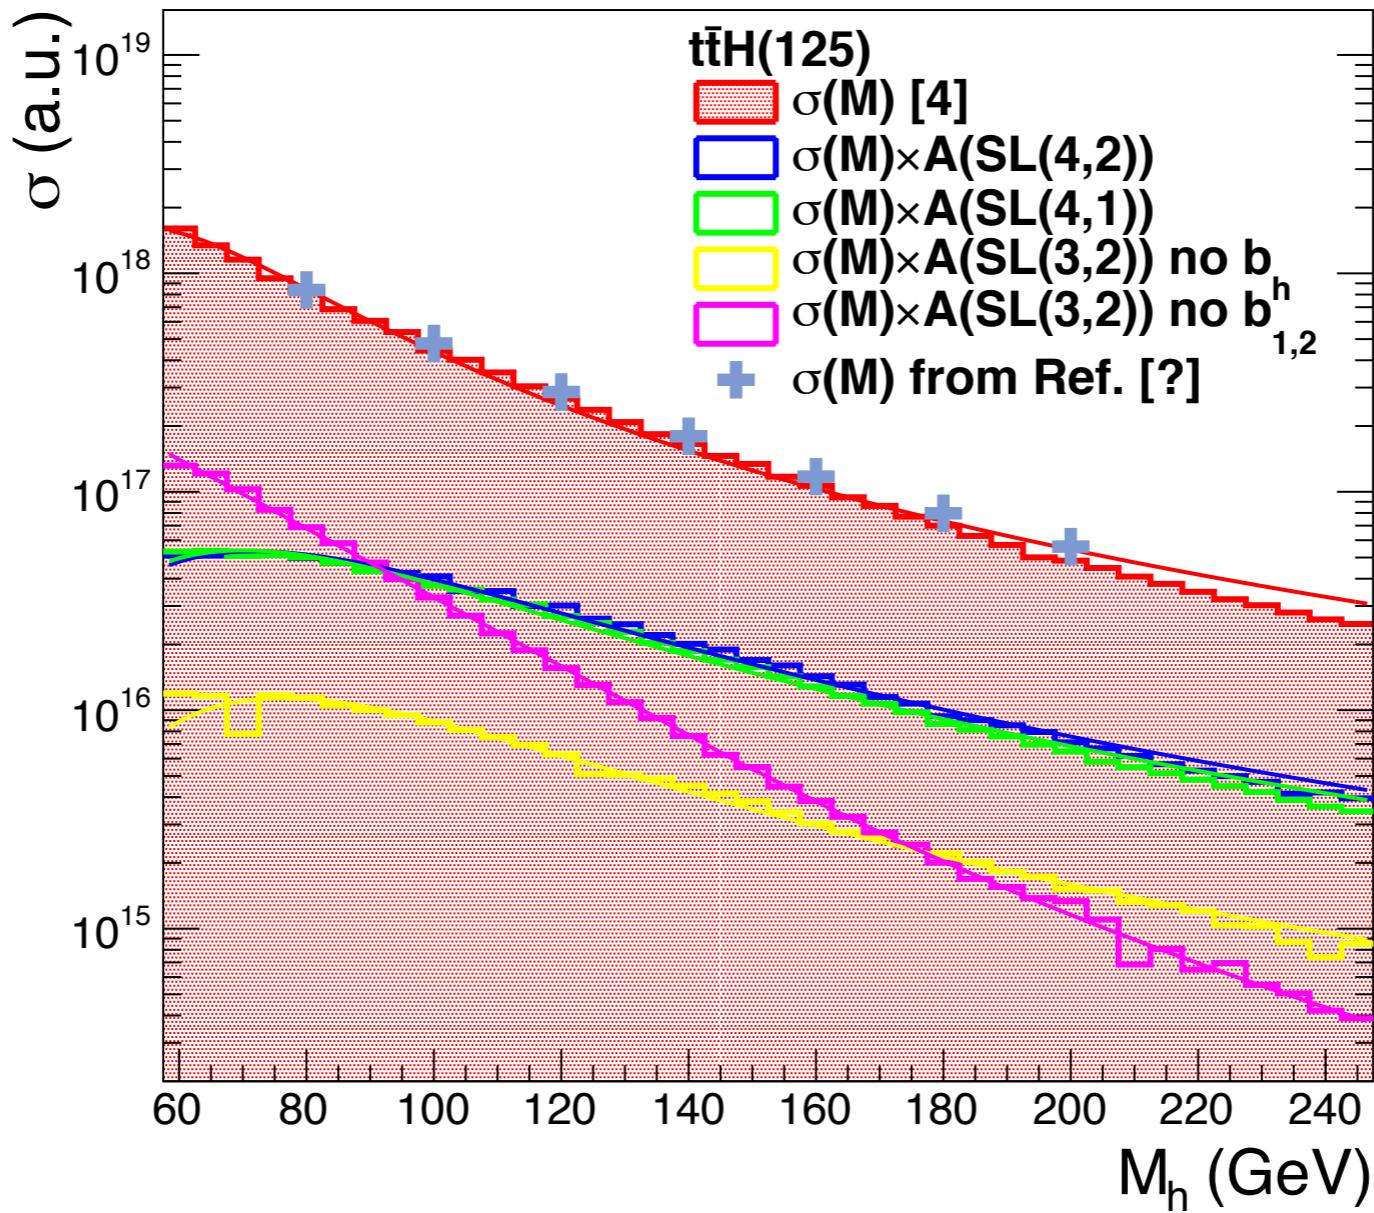

Number of variables	4 (+1)	6 (+1)	5 (+1)
Number of iterations	5	5	5
Function calls	2000	4000	10000

CPU-time per integral (mean)	0.5 (1.5) s	1.1 (3.2) s	2.3 (6.2) s
Time budget for $ \mathcal{M} _{\text{ME}}^2$	30% (80%)	30% (80%)	30% (80%)

# Comparing with MadWeight

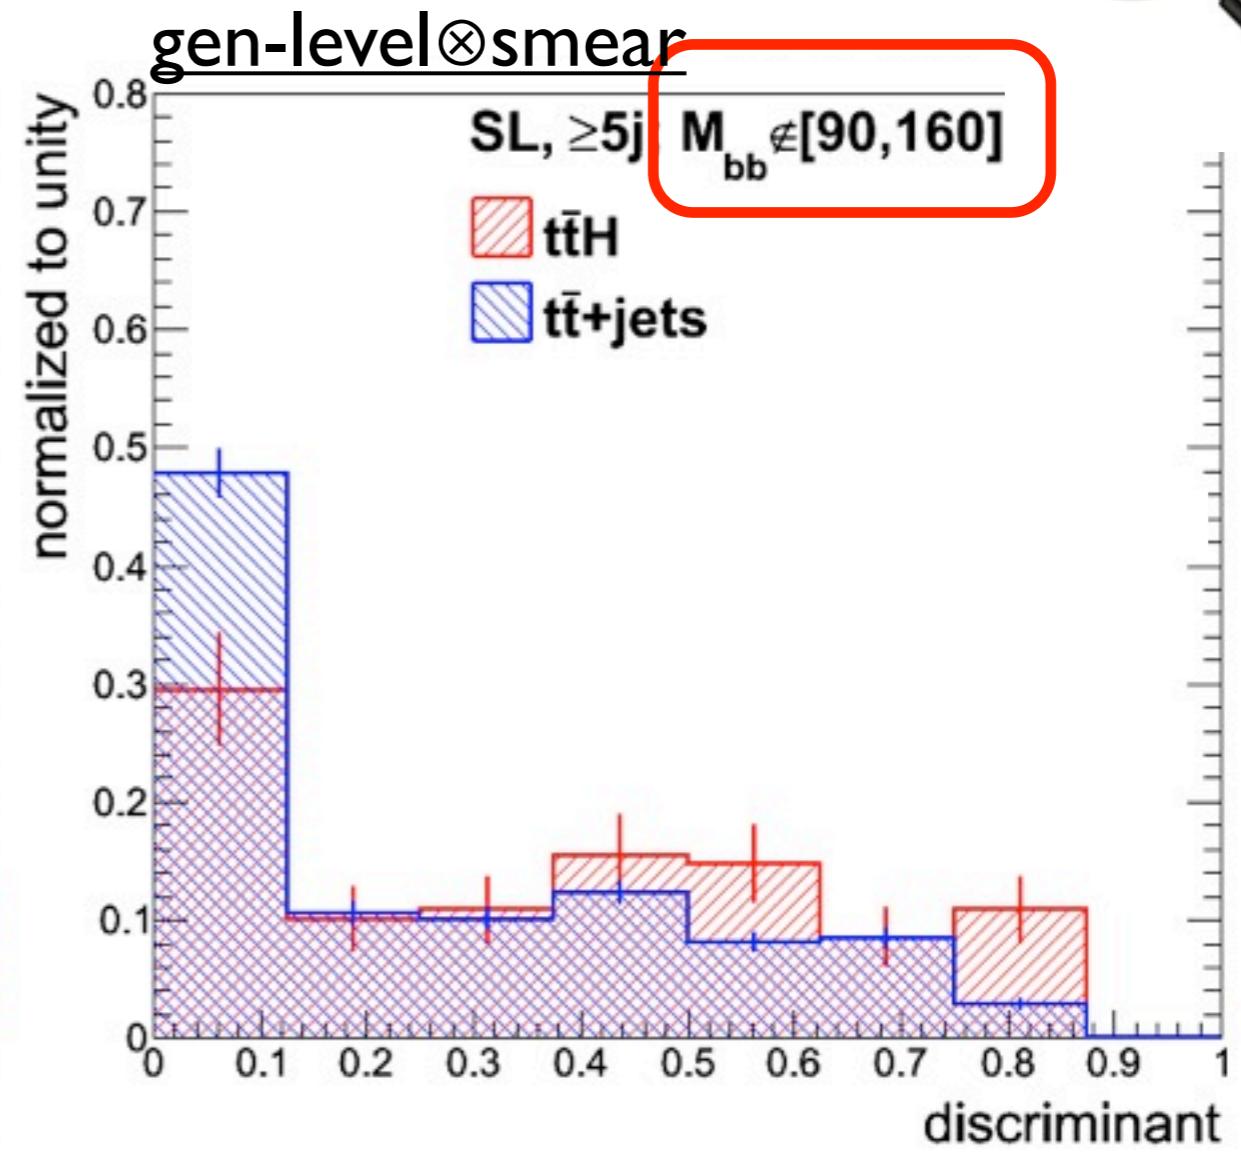

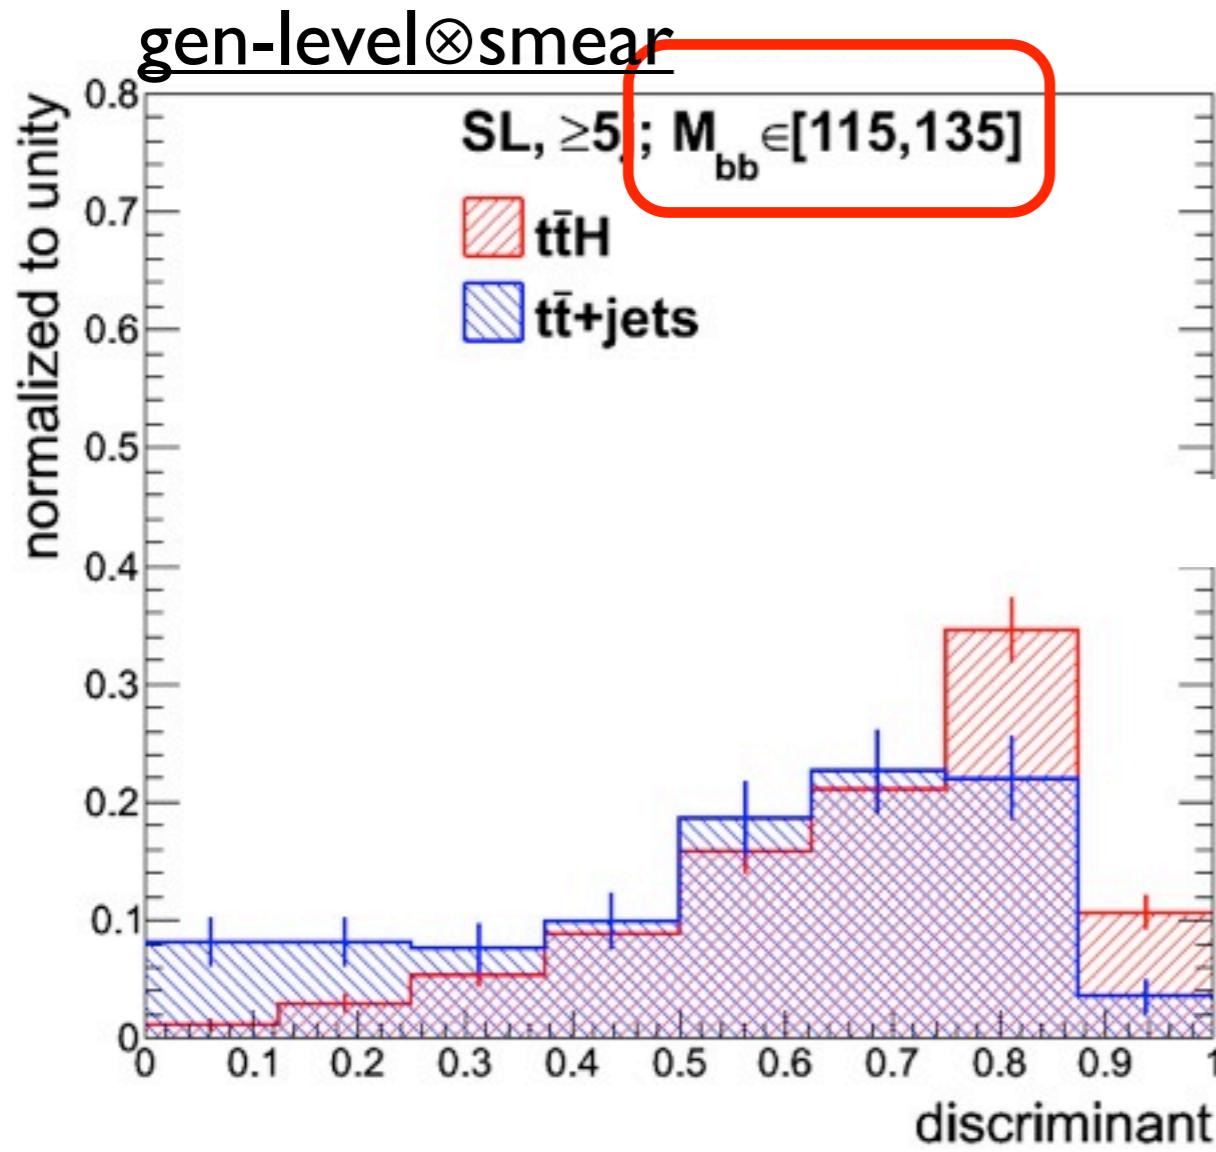

arXiv:1304.6414

# Cross-section

# Digression I: the Higgs mass

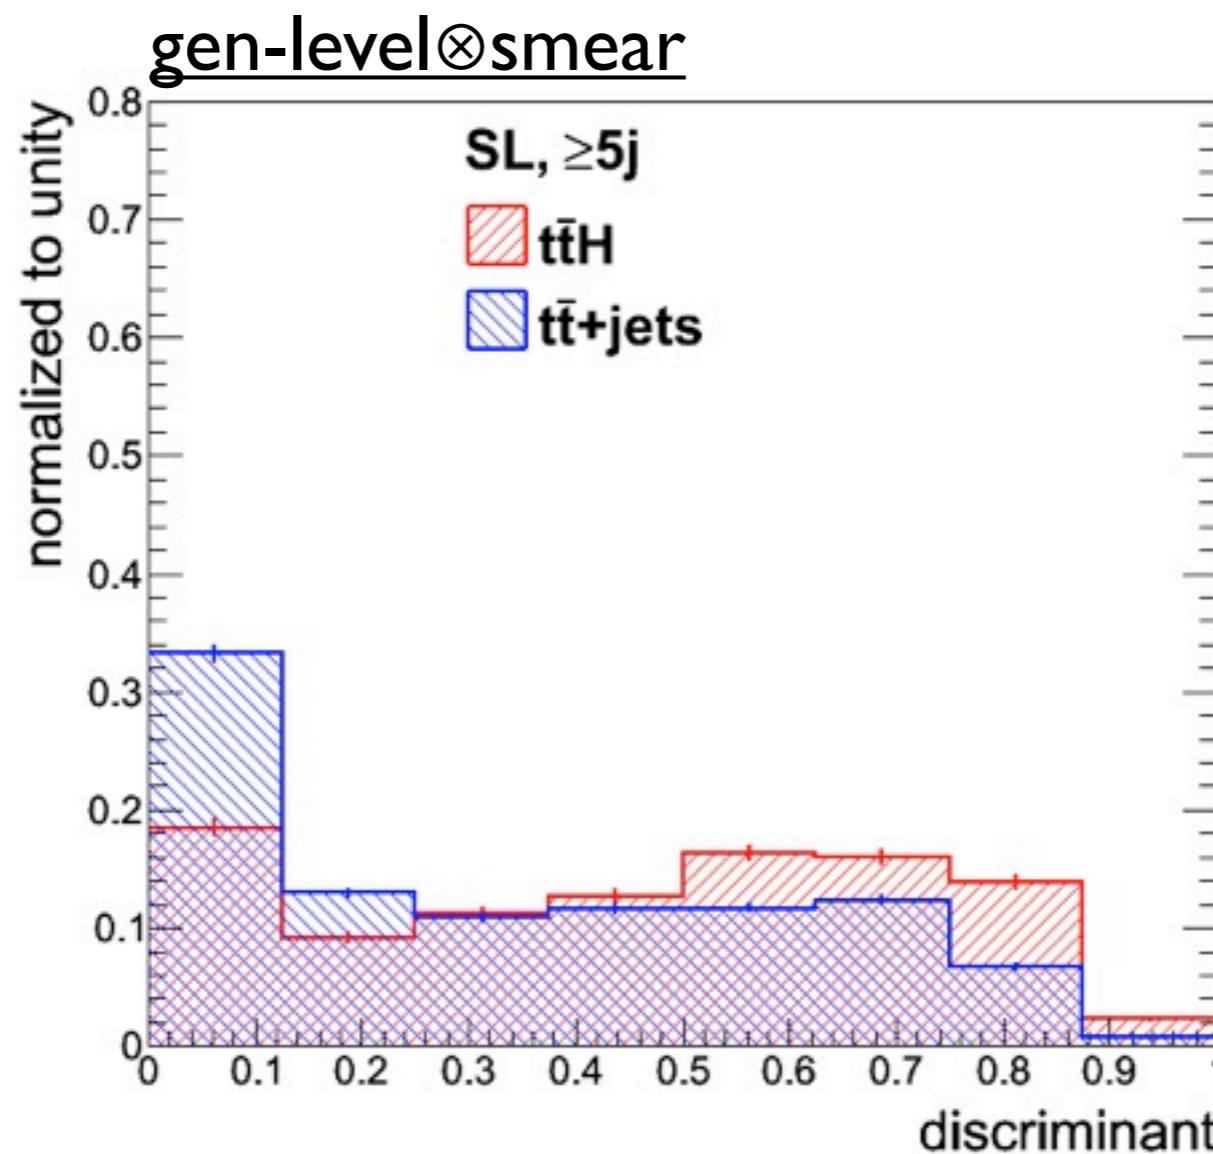

- *ttbb* events w/  $M(bb) \approx 125$  indeed look like *ttH*!
  - ▶ but not identical  $\Leftrightarrow$  the ME is sensitive also to the other variables
- *ttH* events w/  $M(bb) \neq 125$  (e.g. poor resolution) undistinguishable from *ttbb*

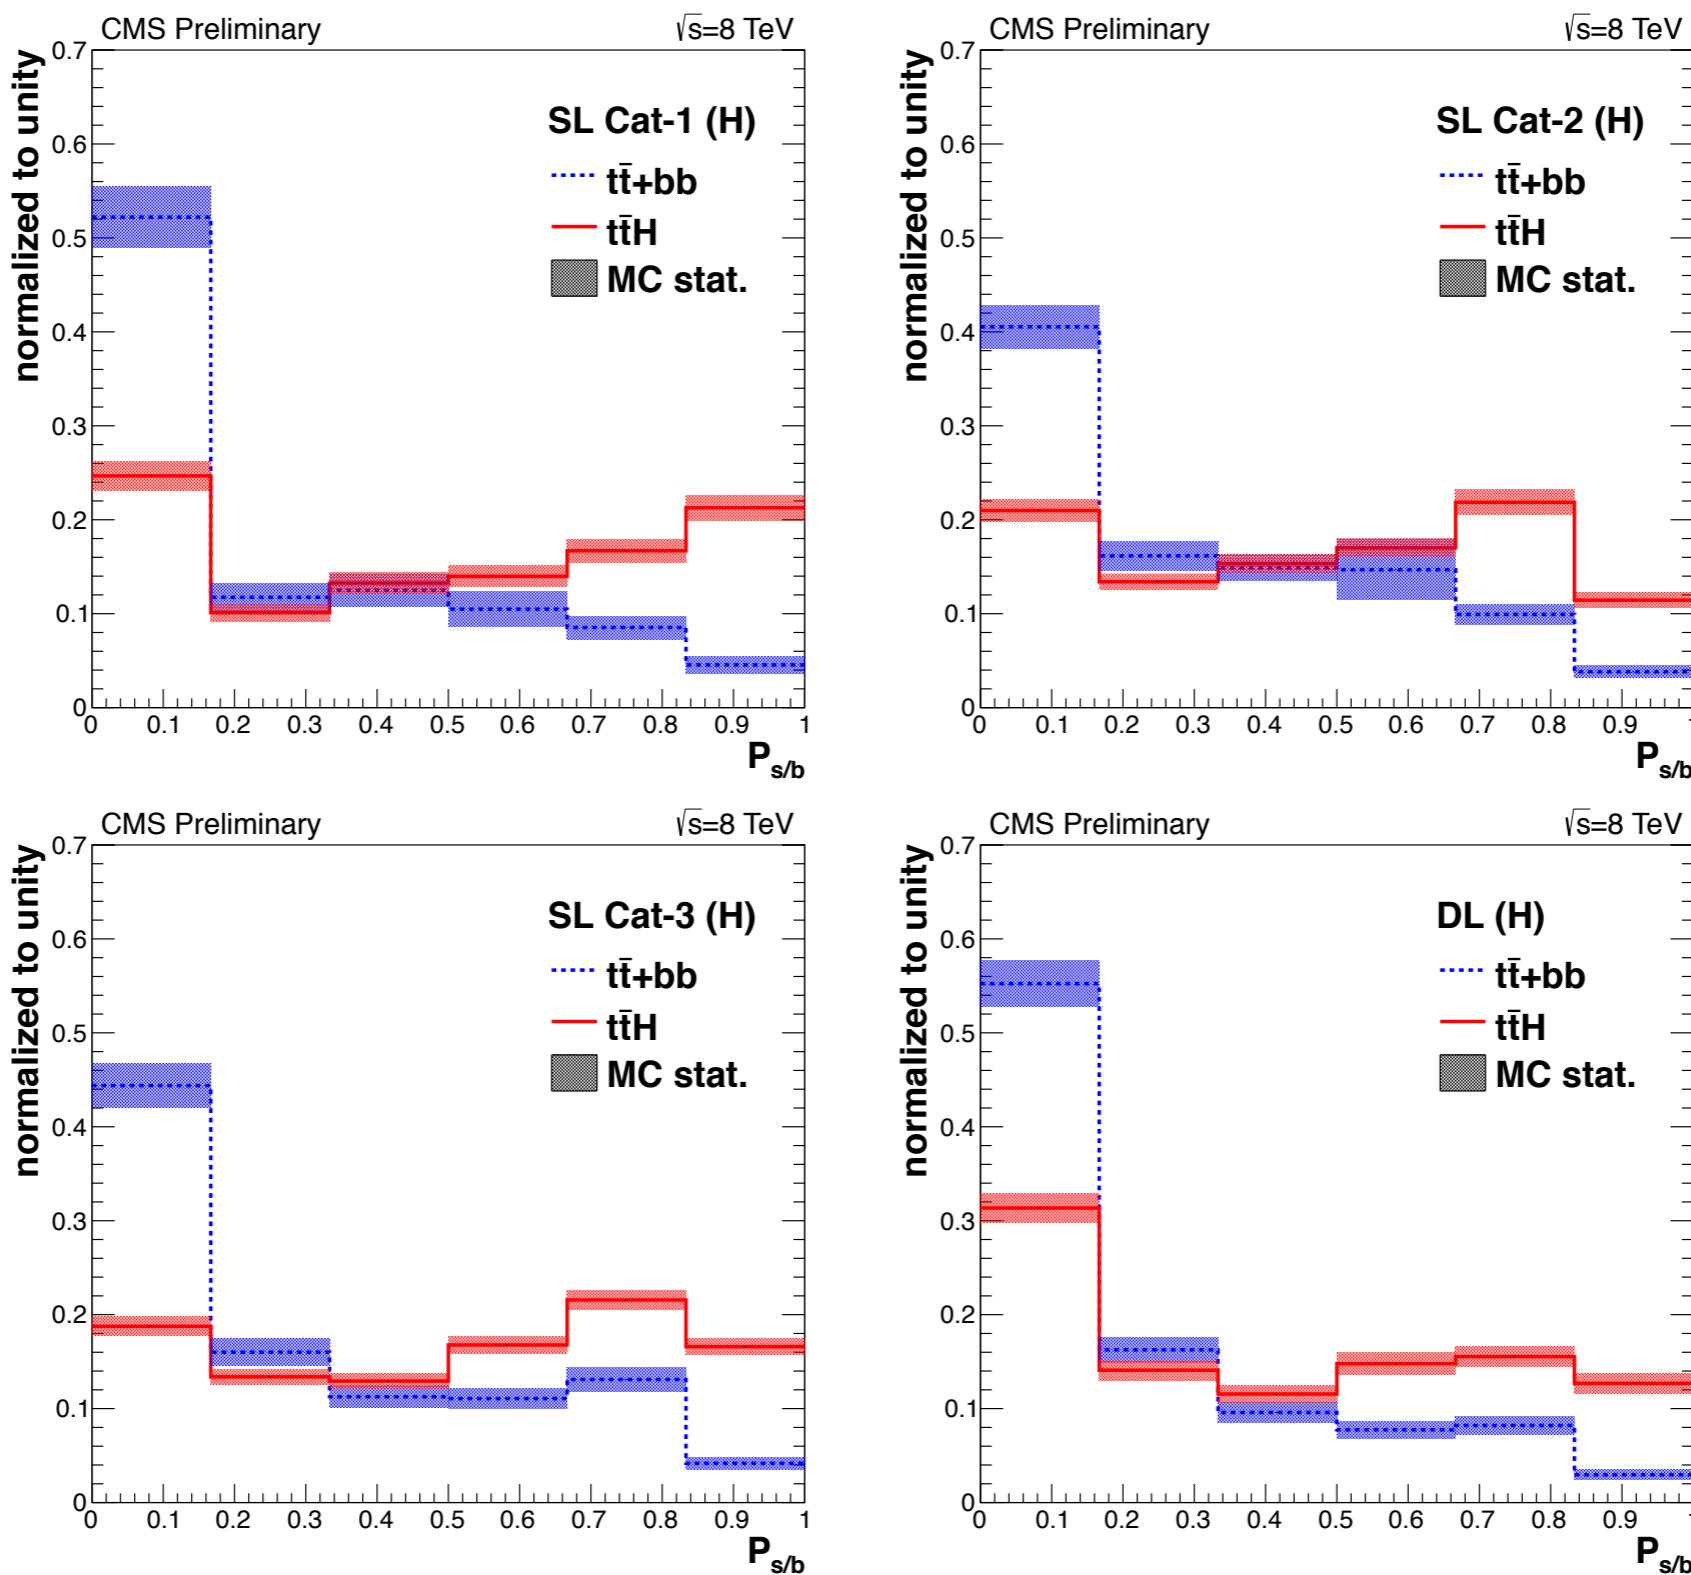

# Digression II: wrong hypothesis

- If the event does not fulfill the *tested* ME hypo, the weight is broadly distributed
  - ▶ yet,  $t\bar{t}H$  remains slightly more “signal-like”

# Shape comparison: $t\bar{t}+bb$ vs $t\bar{t}H$

# DLM continued

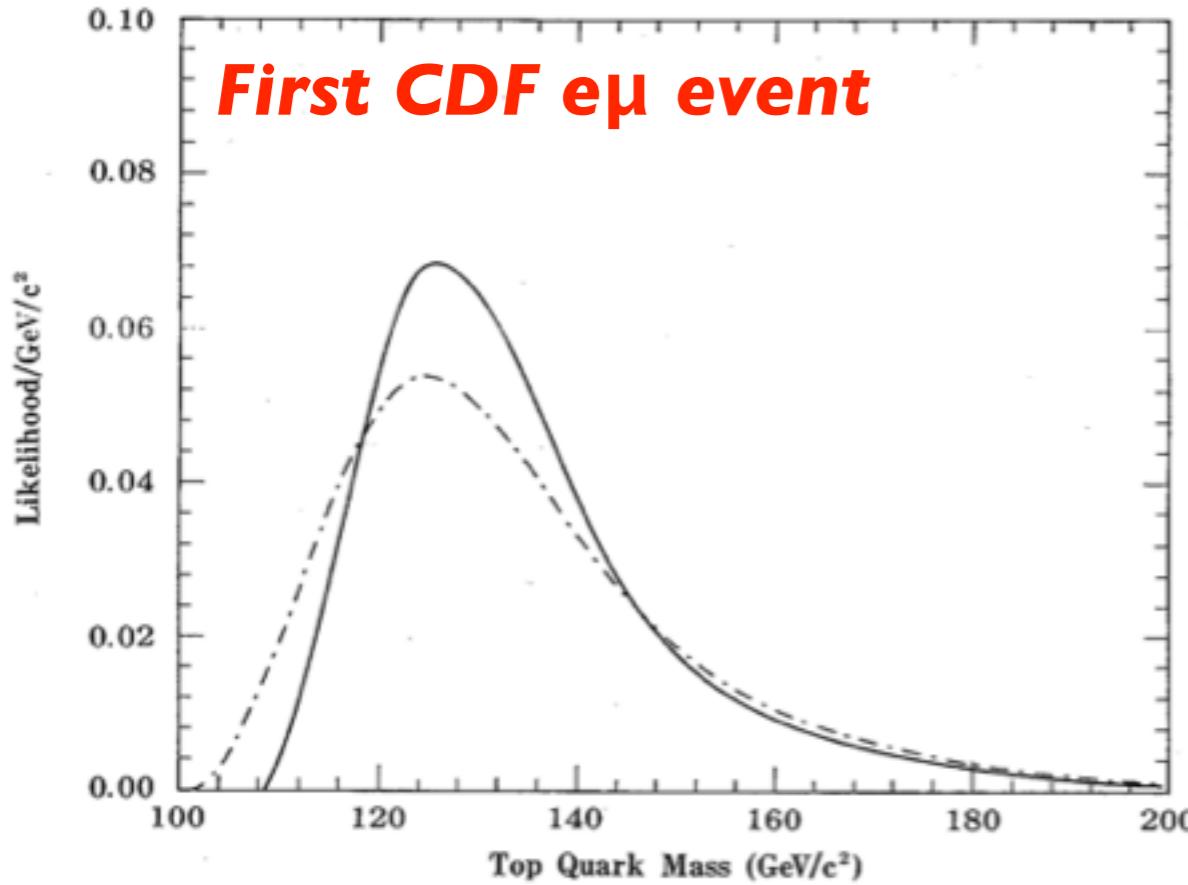

First complete formulation of a dynamical mass likelihood

►  $A + B \rightarrow C + D \rightarrow \text{invisible}$

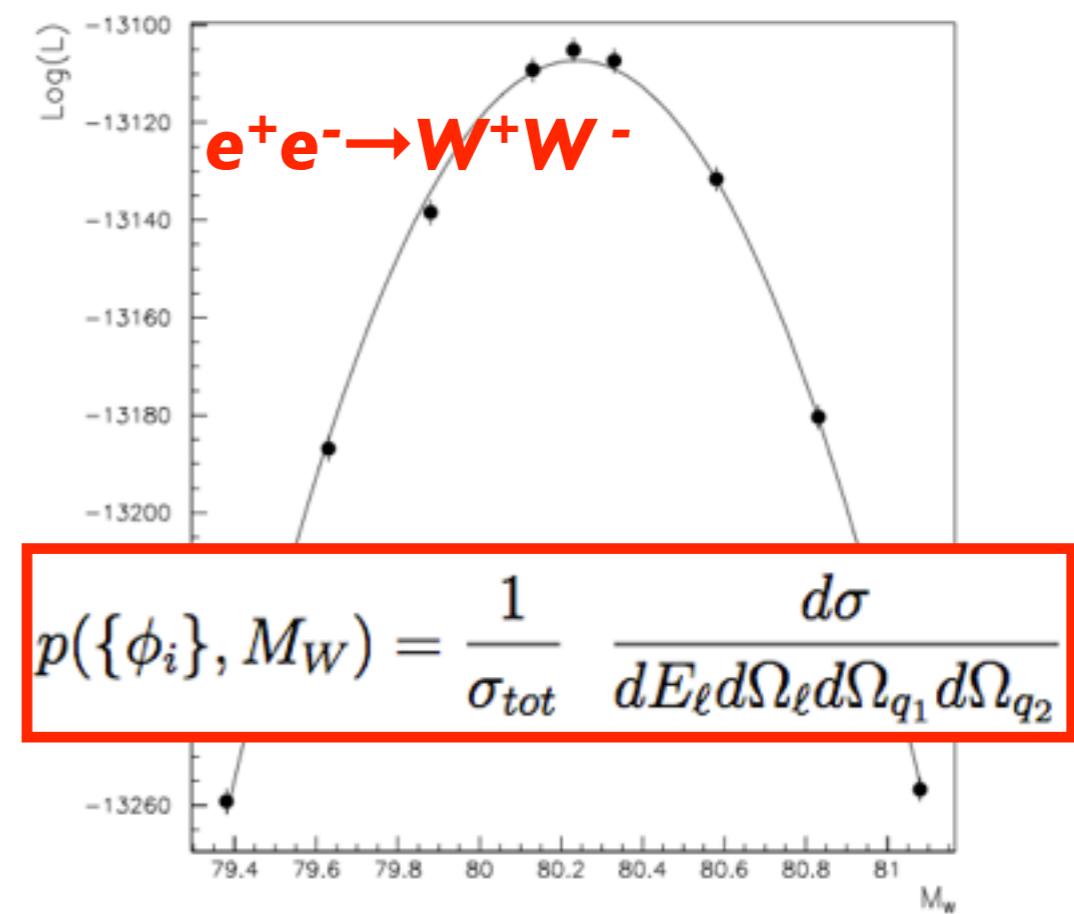

K. Kondo,  
J. Phys. Soc. Jap 60 836 (1991)

$$dP = N' \frac{1}{|(A \cdot B)|} \delta^4(A + B - C - D) |M|^2 \cdot \left( \prod_{i=1}^l \frac{1}{c_{i0}} \prod_{j=1}^m \frac{1}{d_j} \right) d\Xi d\zeta_j^* \\ \times F_{1A}(A_x, A_y, z_a, Q^2) F_{2B}(B_x B_y, z_b, Q^2) dA_x dA_y dz_a dB_x dB_y dz_b dm_c dm_d,$$

K. Kondo, J. Phys. Soc. Jap 62 1177 (1993)

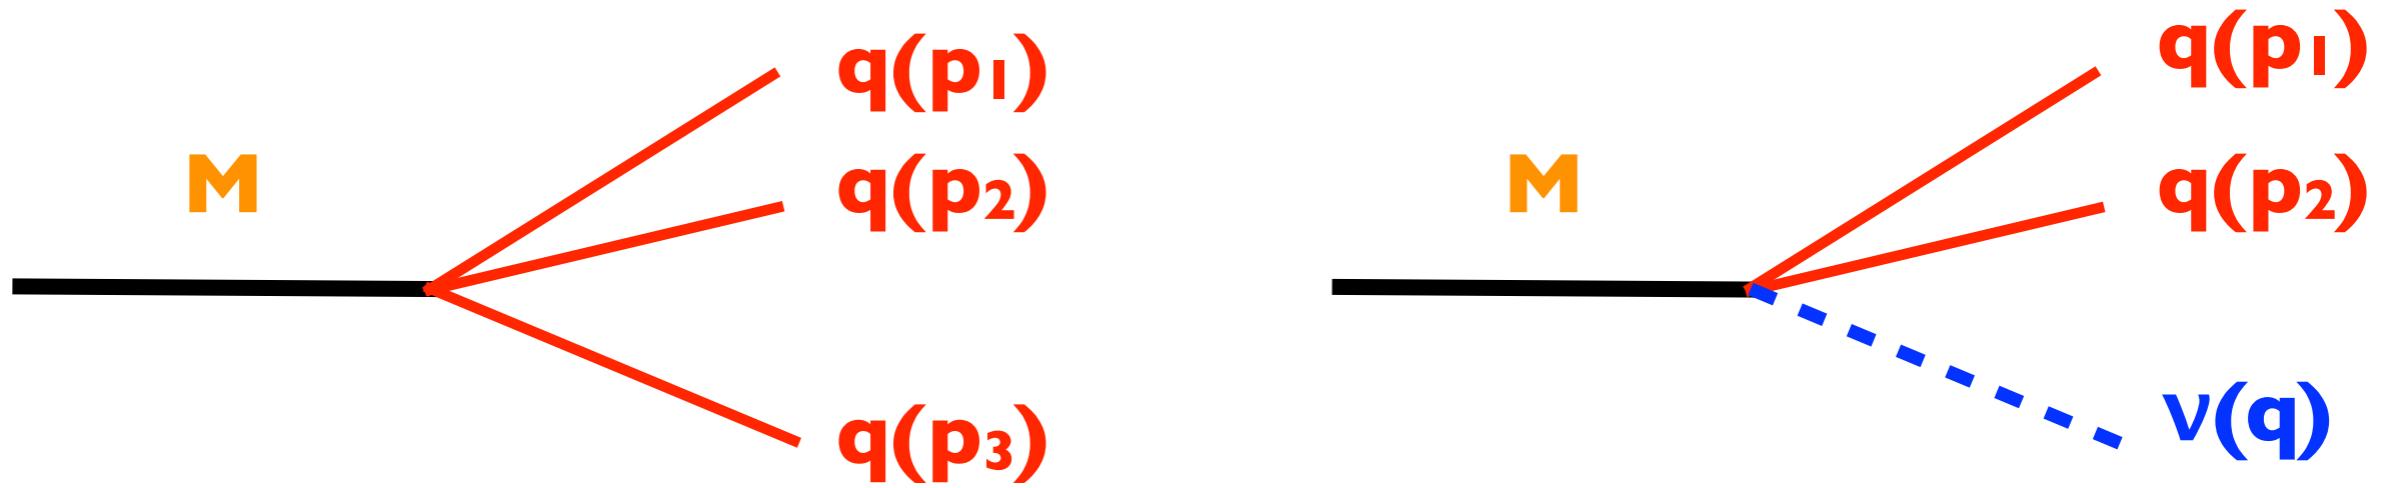

F. Berends et al., PLB 417 (1998) 385

# A toy example

K. Kondo, J. Phys. Soc. Jap 57 4126 (1988)

K. Kondo, J. Phys. Soc. Jap 60 836 (1991)

$$M = \sqrt{(p_1 + p_2 + p_3)^2}$$

$$M(\vec{q}) = \sqrt{(p_1 + p_2 + q)^2}$$

If decay governed by some amplitude,  
not all configurations equally likely:

$$dP(\vec{q}) = |\mathcal{M}(p_1, p_2, q)|^2 d\vec{q}$$

Recover full kinematics  
by applying the  
concept of probability:

$$\frac{dP}{dM}(M) = \int d\vec{q} |\mathcal{M}(p_1, p_2, q)|^2 \times \delta(M - M(p_1, p_2, q))$$

# The event likelihood

## Complexity of the problem scales with dimensions

- ▶ if both  $\dim(\mathbf{Y})$  and  $\dim(\boldsymbol{\theta})$  small  $\Rightarrow$  MC methods
  - e.g. fill histograms using MC simulation at different  $\boldsymbol{\theta}$  values
- ▶ else MC methods impractical
  - analytical approach

- A set of ancillary variables  $\mathbf{X}$
- A prior  $\pi(\mathbf{X}; \boldsymbol{\theta})$
- A conditional pdf  $W(\mathbf{Y}|\mathbf{X})$

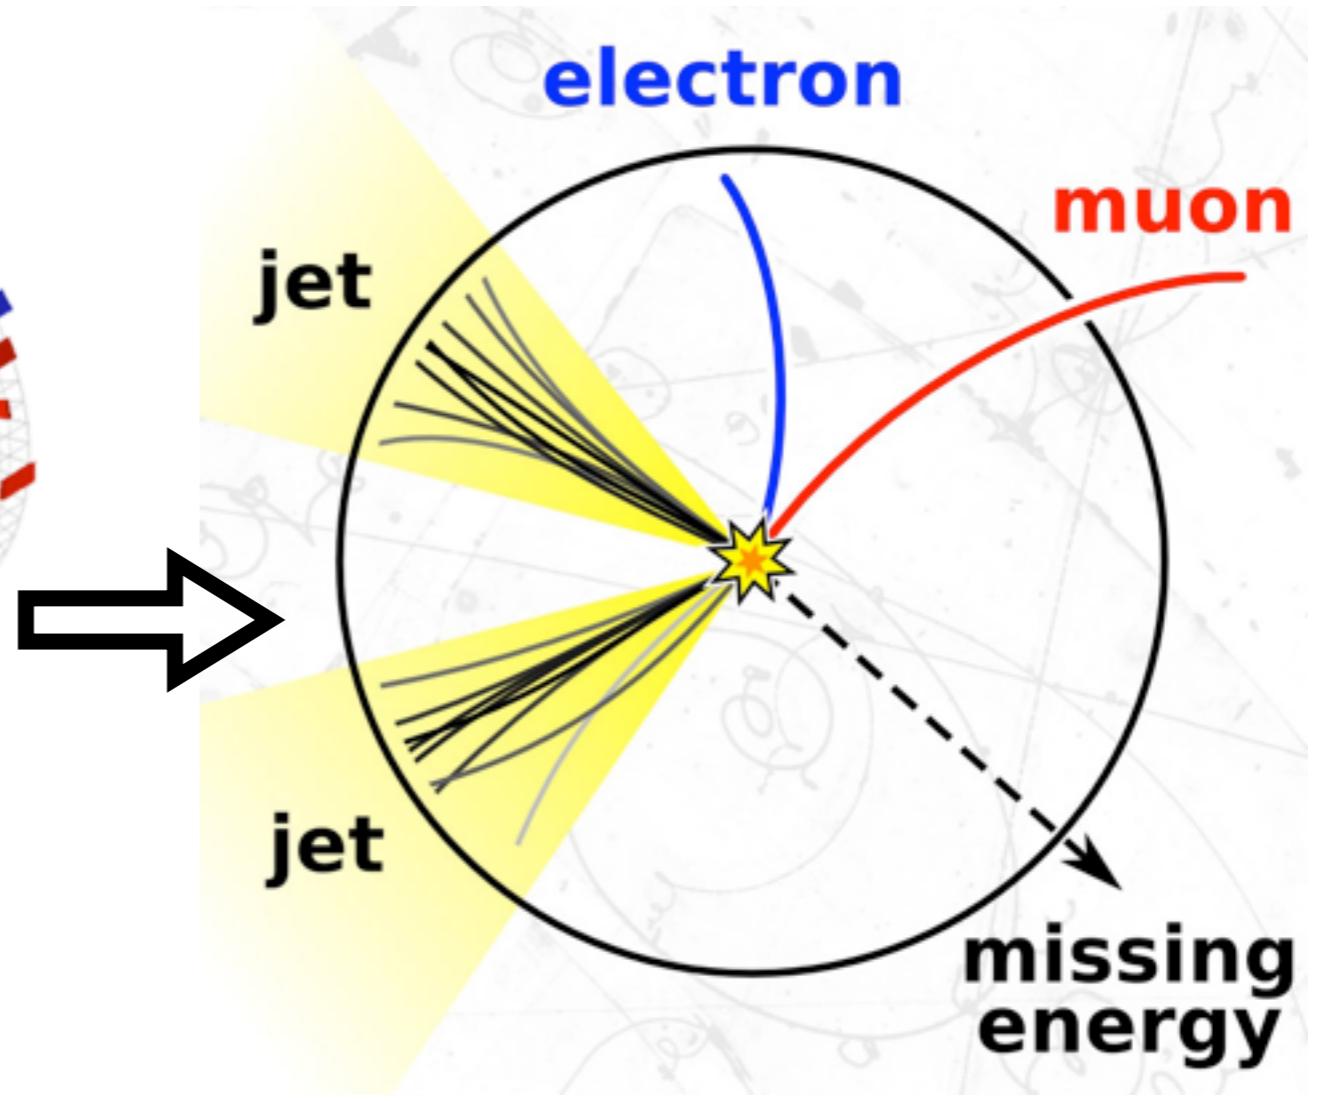

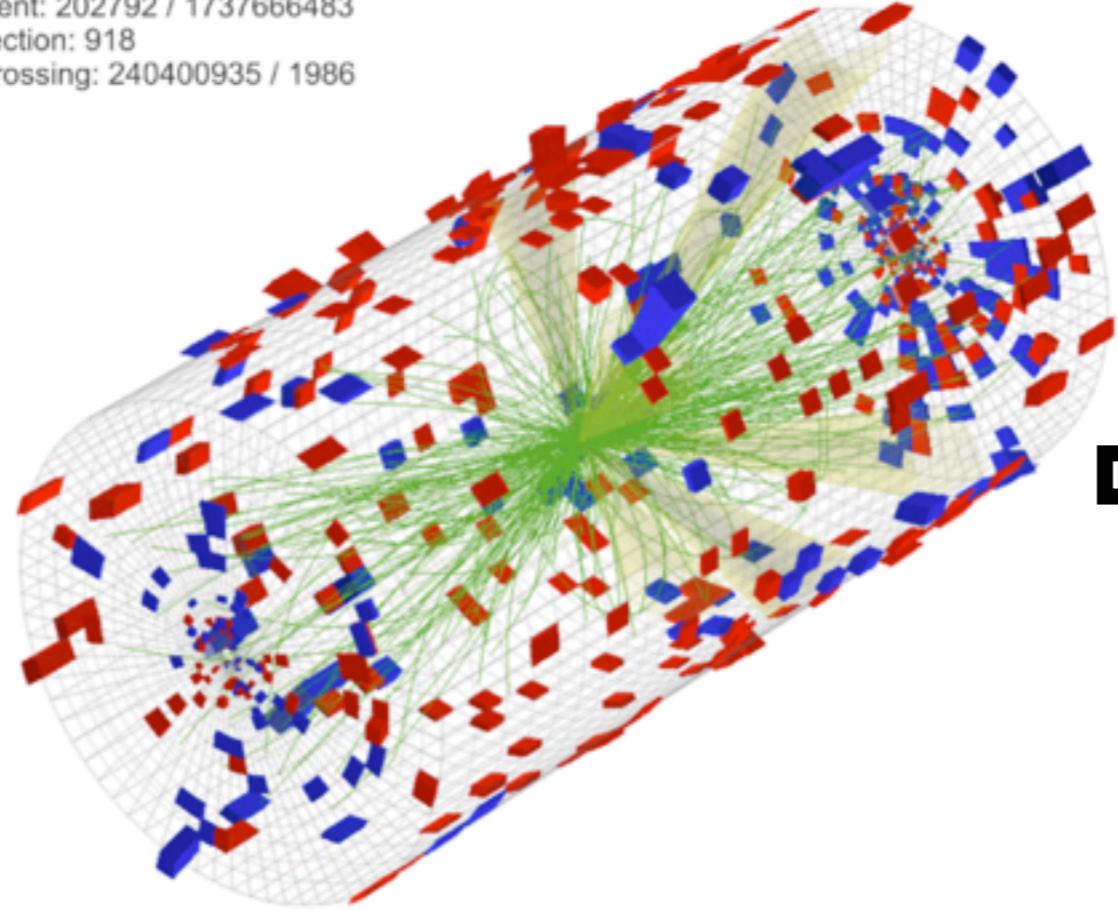

$$\mathcal{L}(Y; \boldsymbol{\theta}) = \int \pi(\mathbf{X}; \boldsymbol{\theta}) \cdot W(Y|\mathbf{X}) d\mathbf{X}$$

*Encompasses  
all of the prior  
knowledge*

*any new  
measurement adds  
a bit of info*

# The event likelihood

CMS Experiment at LHC, CERN  
Data recorded: Thu Sep 13 05:21:23 2012 CEST  
Run/Event: 202792 / 1737666483  
Lumi section: 918  
Orbit/Crossing: 240400935 / 1986

Clearly not feasible to determine a full “detector likelihood”

- ▶ but detector can be reduced down to the level of “physics objects”
  - proxies of ideal asymptotic states (quarks, leptons, ...)
  - still, every particle is at least a 4-dimensional variate

# Dynamical Likelihood Models

Problem: retain maximal information on dynamical parameters even in presence of non-reconstructed particles

- ▶ especially relevant at hadron colliders

**Probability density on the best measured variables**

$$\frac{dP}{dX_m} = \int dX_n \pi(X_m, X_n)$$

**Integrate out poorly measured ones using their theory prior**

## Dynamical Likelihood Method for Reconstruction of Events with Missing Momentum.

### I. Method and Toy Models

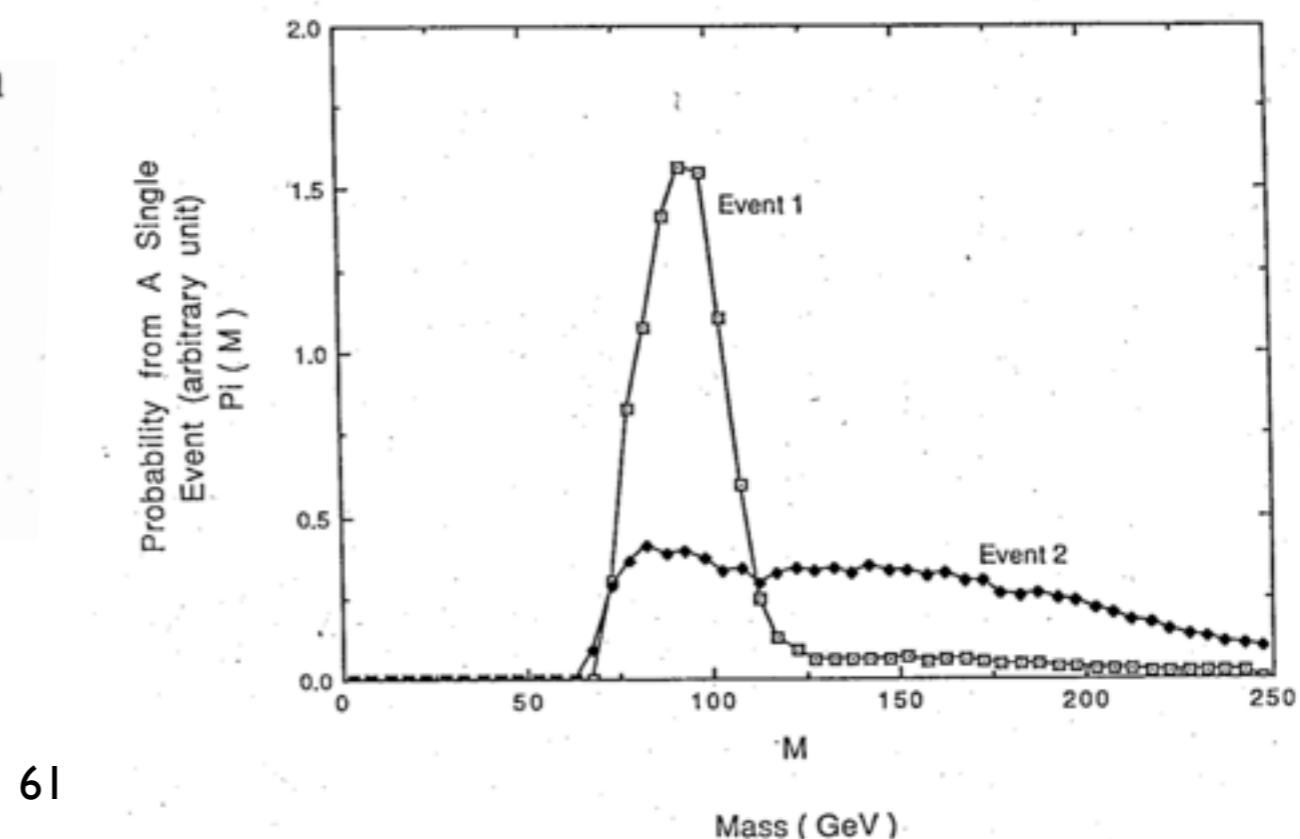

Kunitaka KONDO

University of Tsukuba, Ibaraki 305

(Received July 22, 1988)

K. Kondo, J. Phys. Soc. Jap 57 4126 (1988)

K. Kondo, J. Phys. Soc. Jap 60 836 (1991)

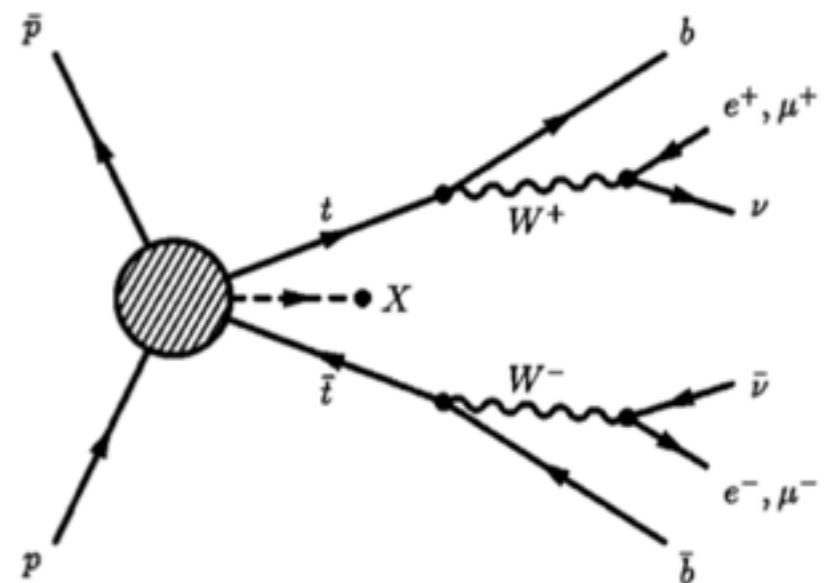

# DLM continued

## First six di-lepton events in D0

- ▶ possibility of using full mass likelihood mentioned, but not yet pursued

D0, PRD 60, 052001 (1999)

$$\mathcal{P}(\{o\}|m_t) \propto \int f(x)f(x)|\mathcal{M}|^2 p(\{o\}|\{v\}) \delta^4 d^{18}\{v\} dx dx, \quad (6)$$

“ Unfortunately this expression involves a multidimensional integral that has to be evaluated numerically and is complicated by the need to include initial and final state gluon radiation. Such higher order effects complicate the reconstruction of the top quark mass substantially and cannot be neglected. We therefore do not attempt to compute the exact probability density given in Eq. (6). Rather, we construct simpler weights that retain sensitivity to the value of the top quark mass but can be evaluated with the available computing resources. We calibrate the effect of the simplification.”

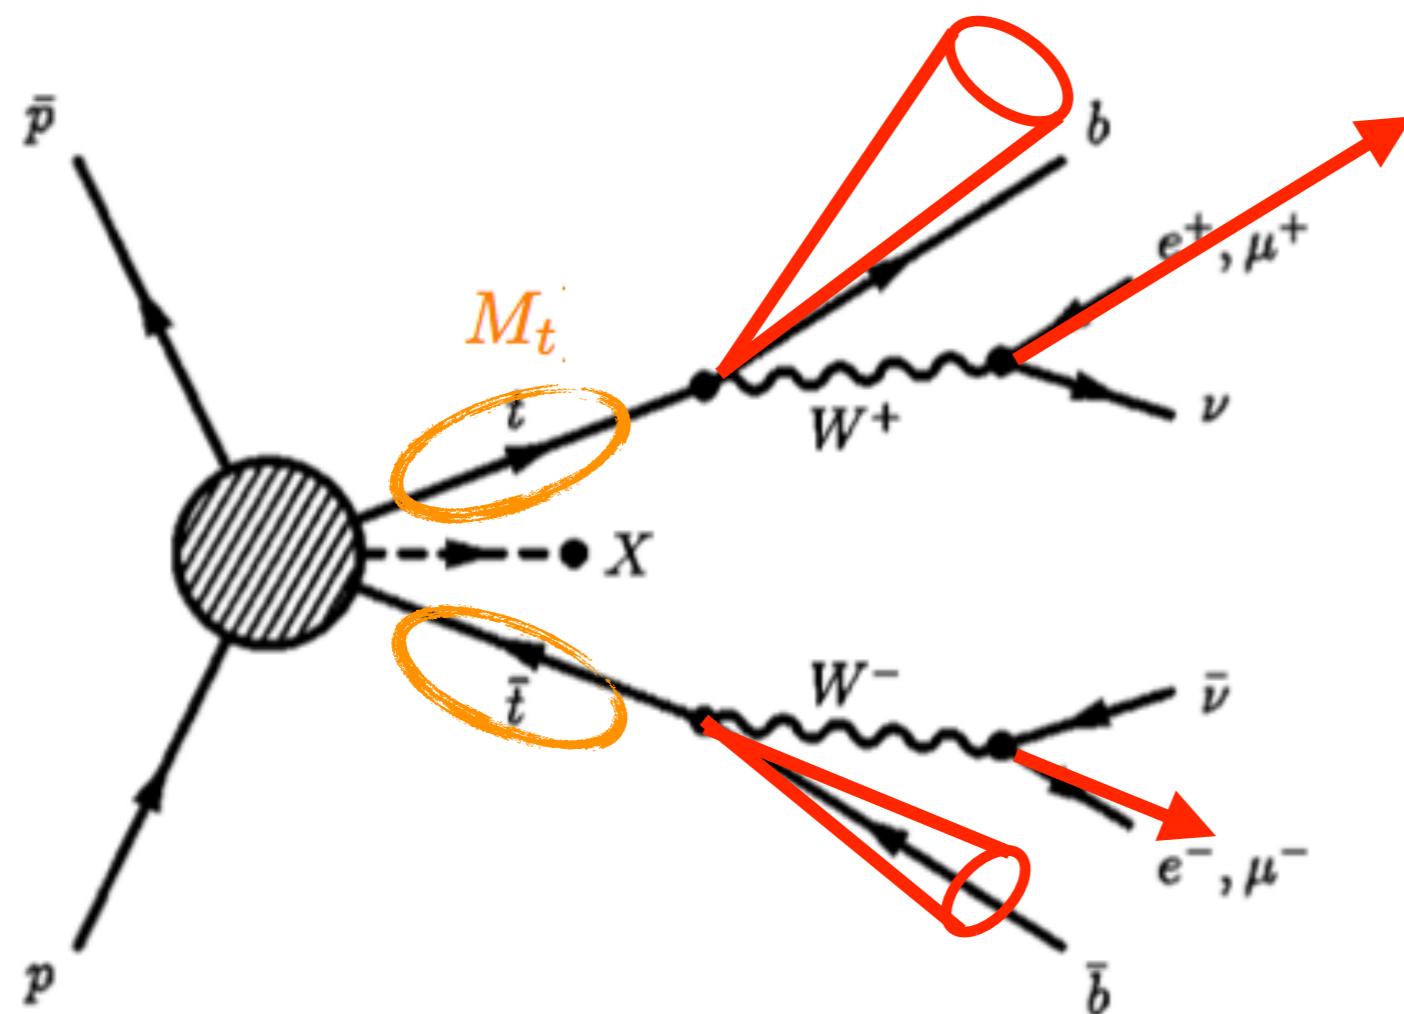

# An example: top mass

**Y** = 4-vectors of jets and leptons

**M<sub>t</sub>** = top quark mass

**X** = 4-vectors of the  $2 \rightarrow 6$  scattering (ancillary variables)

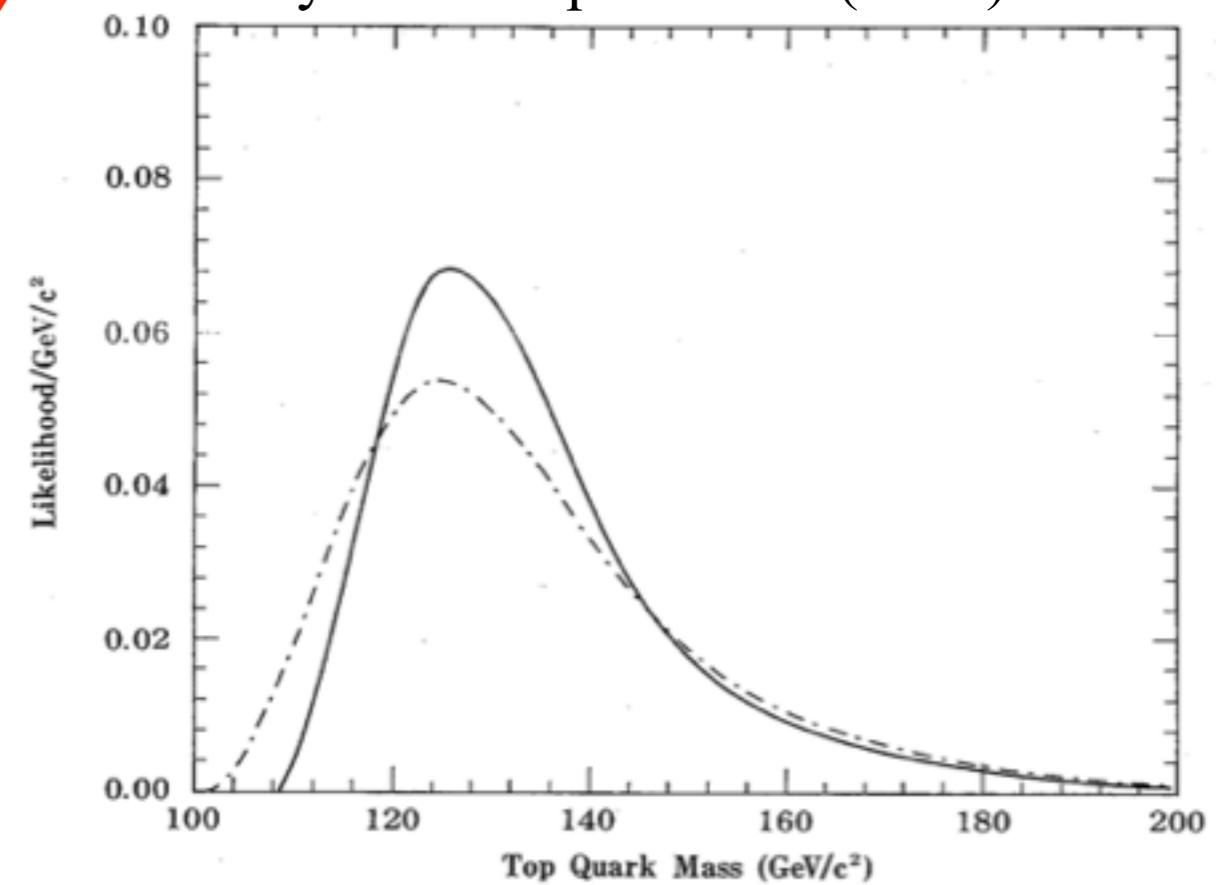

**W(Y|X)** = detector response

Dynamical Likelihood Method for Reconstruction  
of Events with Missing Momentum.

### III. Analysis of a CDF High $P_T$ $e\mu$ Event as $t\bar{t}$ Production

K. Kondo et al.,  
J. Phys. Soc. Jap 62 1177 (1993)

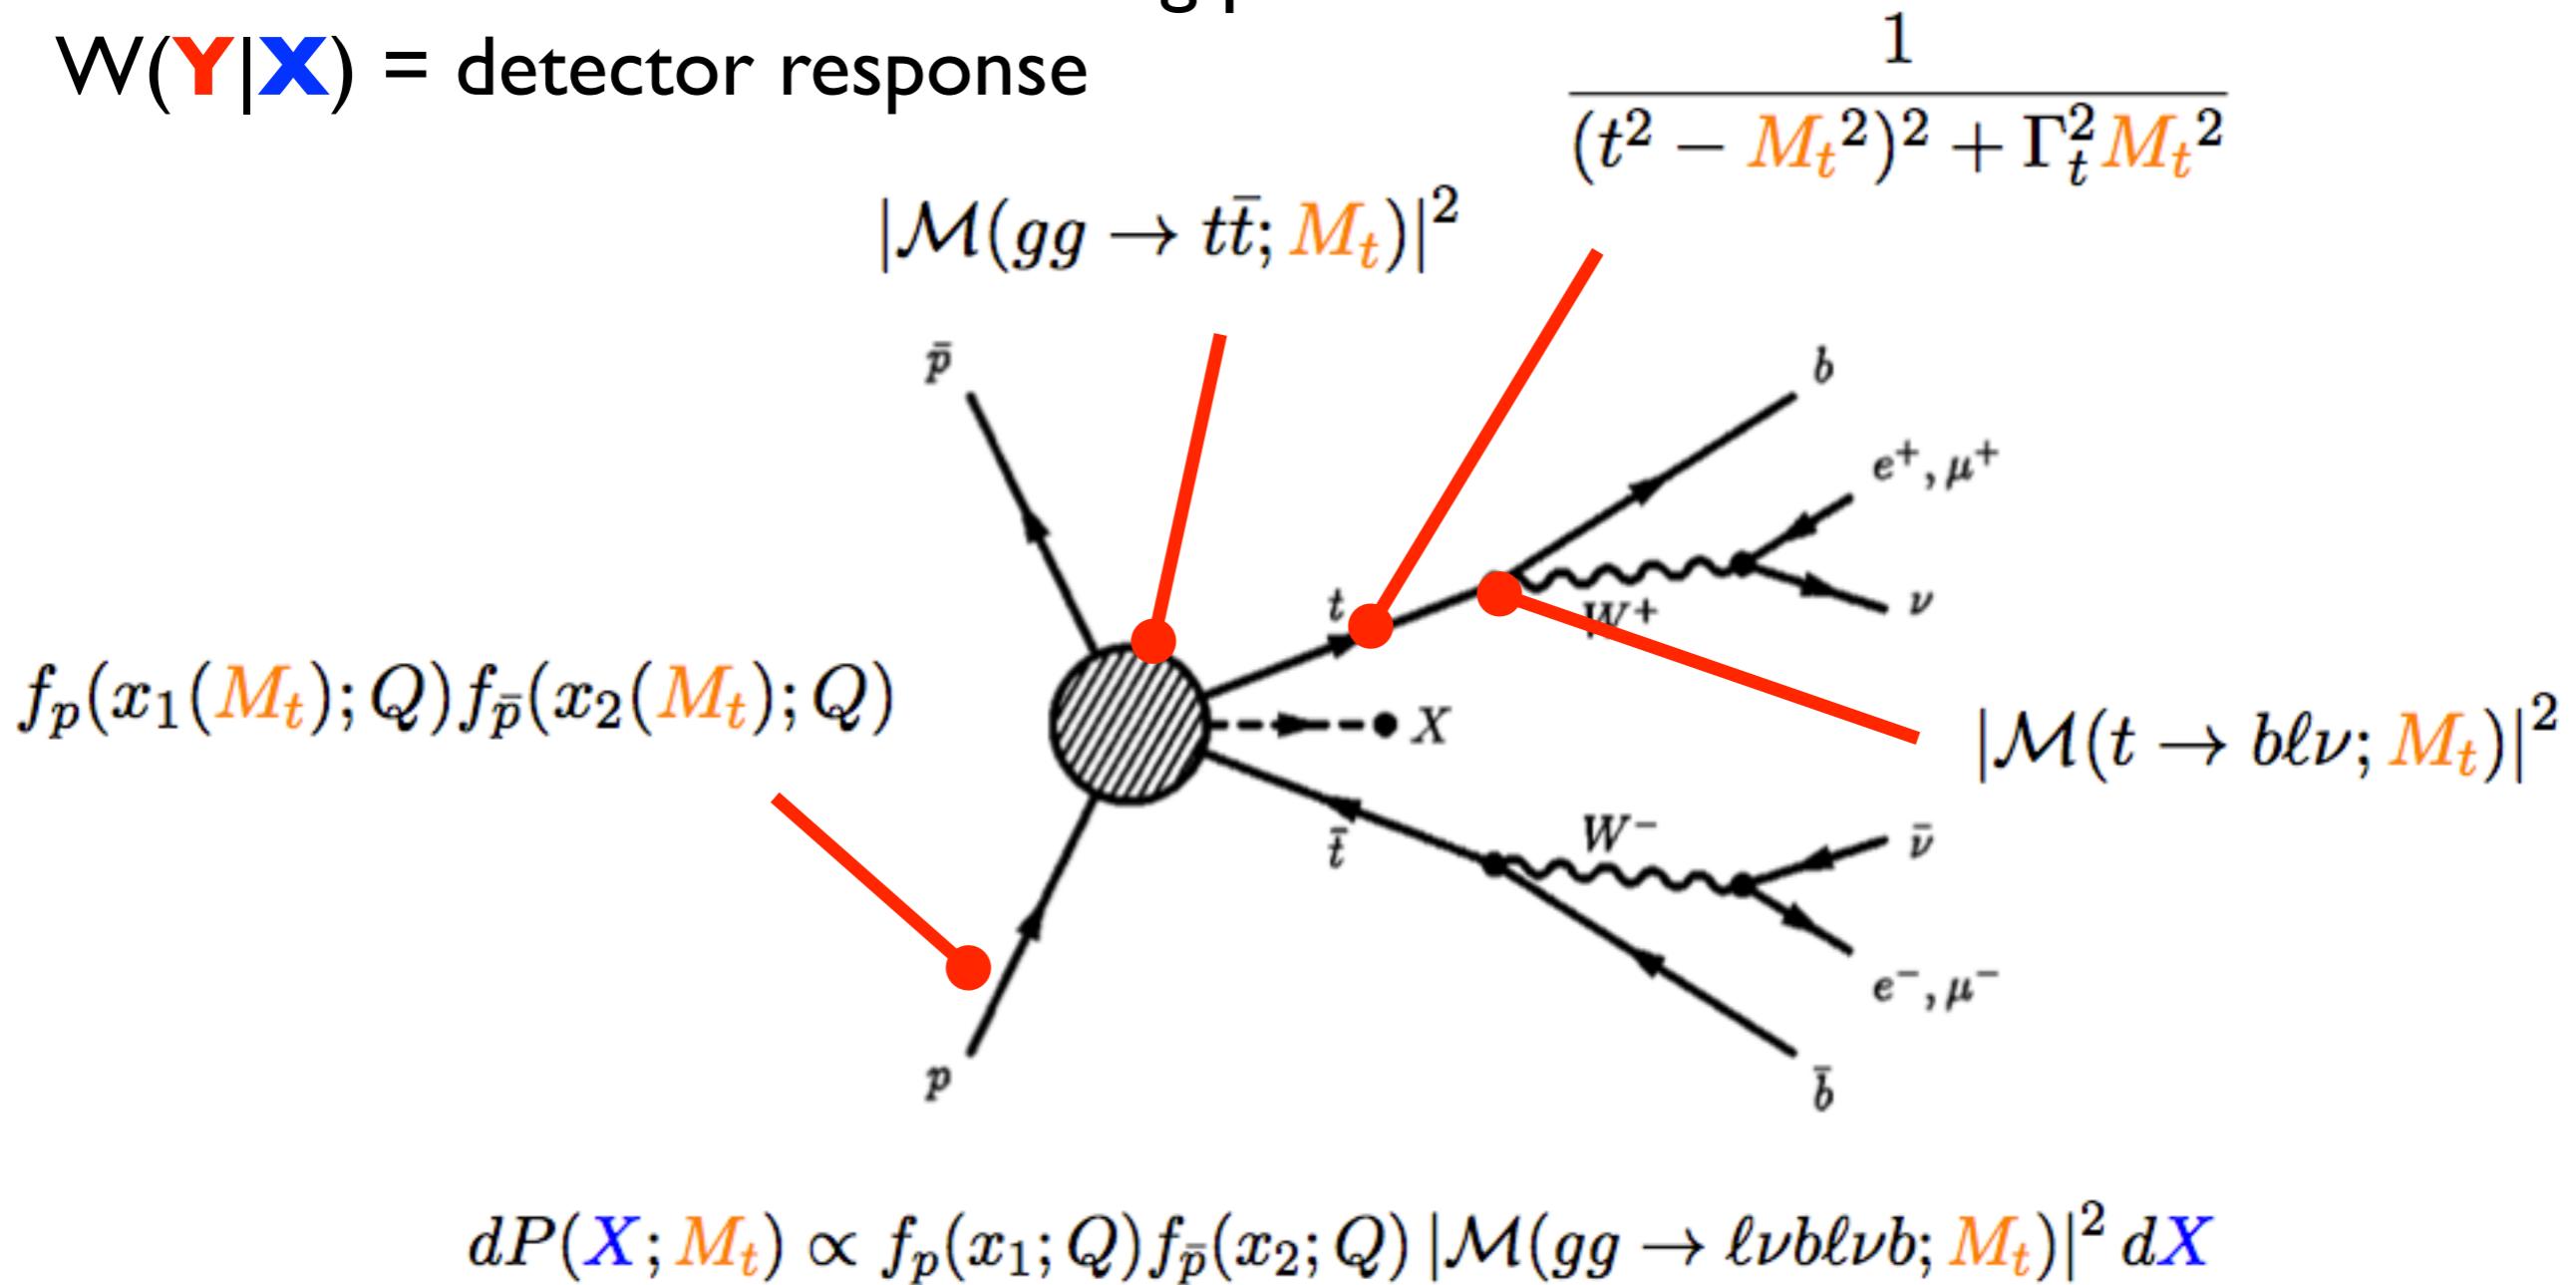

# A typical problem

Typical problem:

“Mass of resonances decaying to invisible or poorly reconstructed particles”

$\textcolor{blue}{X}$  = 4-vector of scattering particles

$W(\textcolor{red}{Y}|\textcolor{blue}{X})$  = detector response

$$dP(\textcolor{blue}{X}; \textcolor{brown}{M}_t) \propto f_p(x_1; Q) f_{\bar{p}}(x_2; Q) |\mathcal{M}(gg \rightarrow \ell\nu b\bar{\ell}\nu b; \textcolor{brown}{M}_t)|^2 d\textcolor{blue}{X}$$

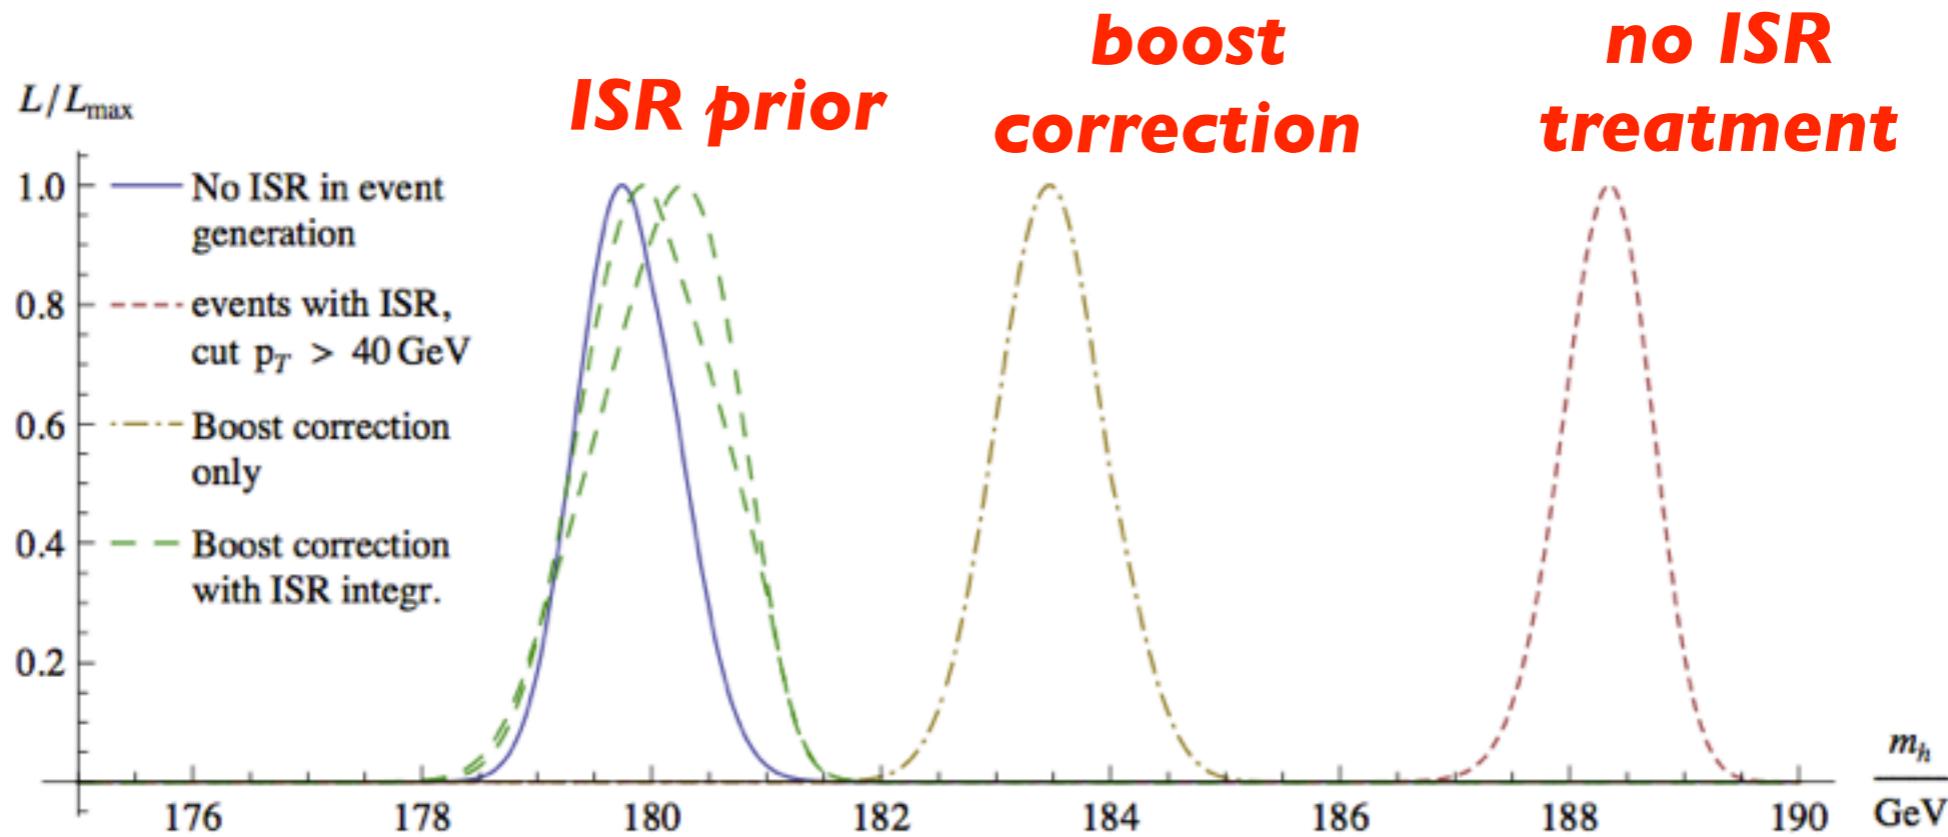

# Summary

# QCD radiation

## Dealing with leading order ME and ISR

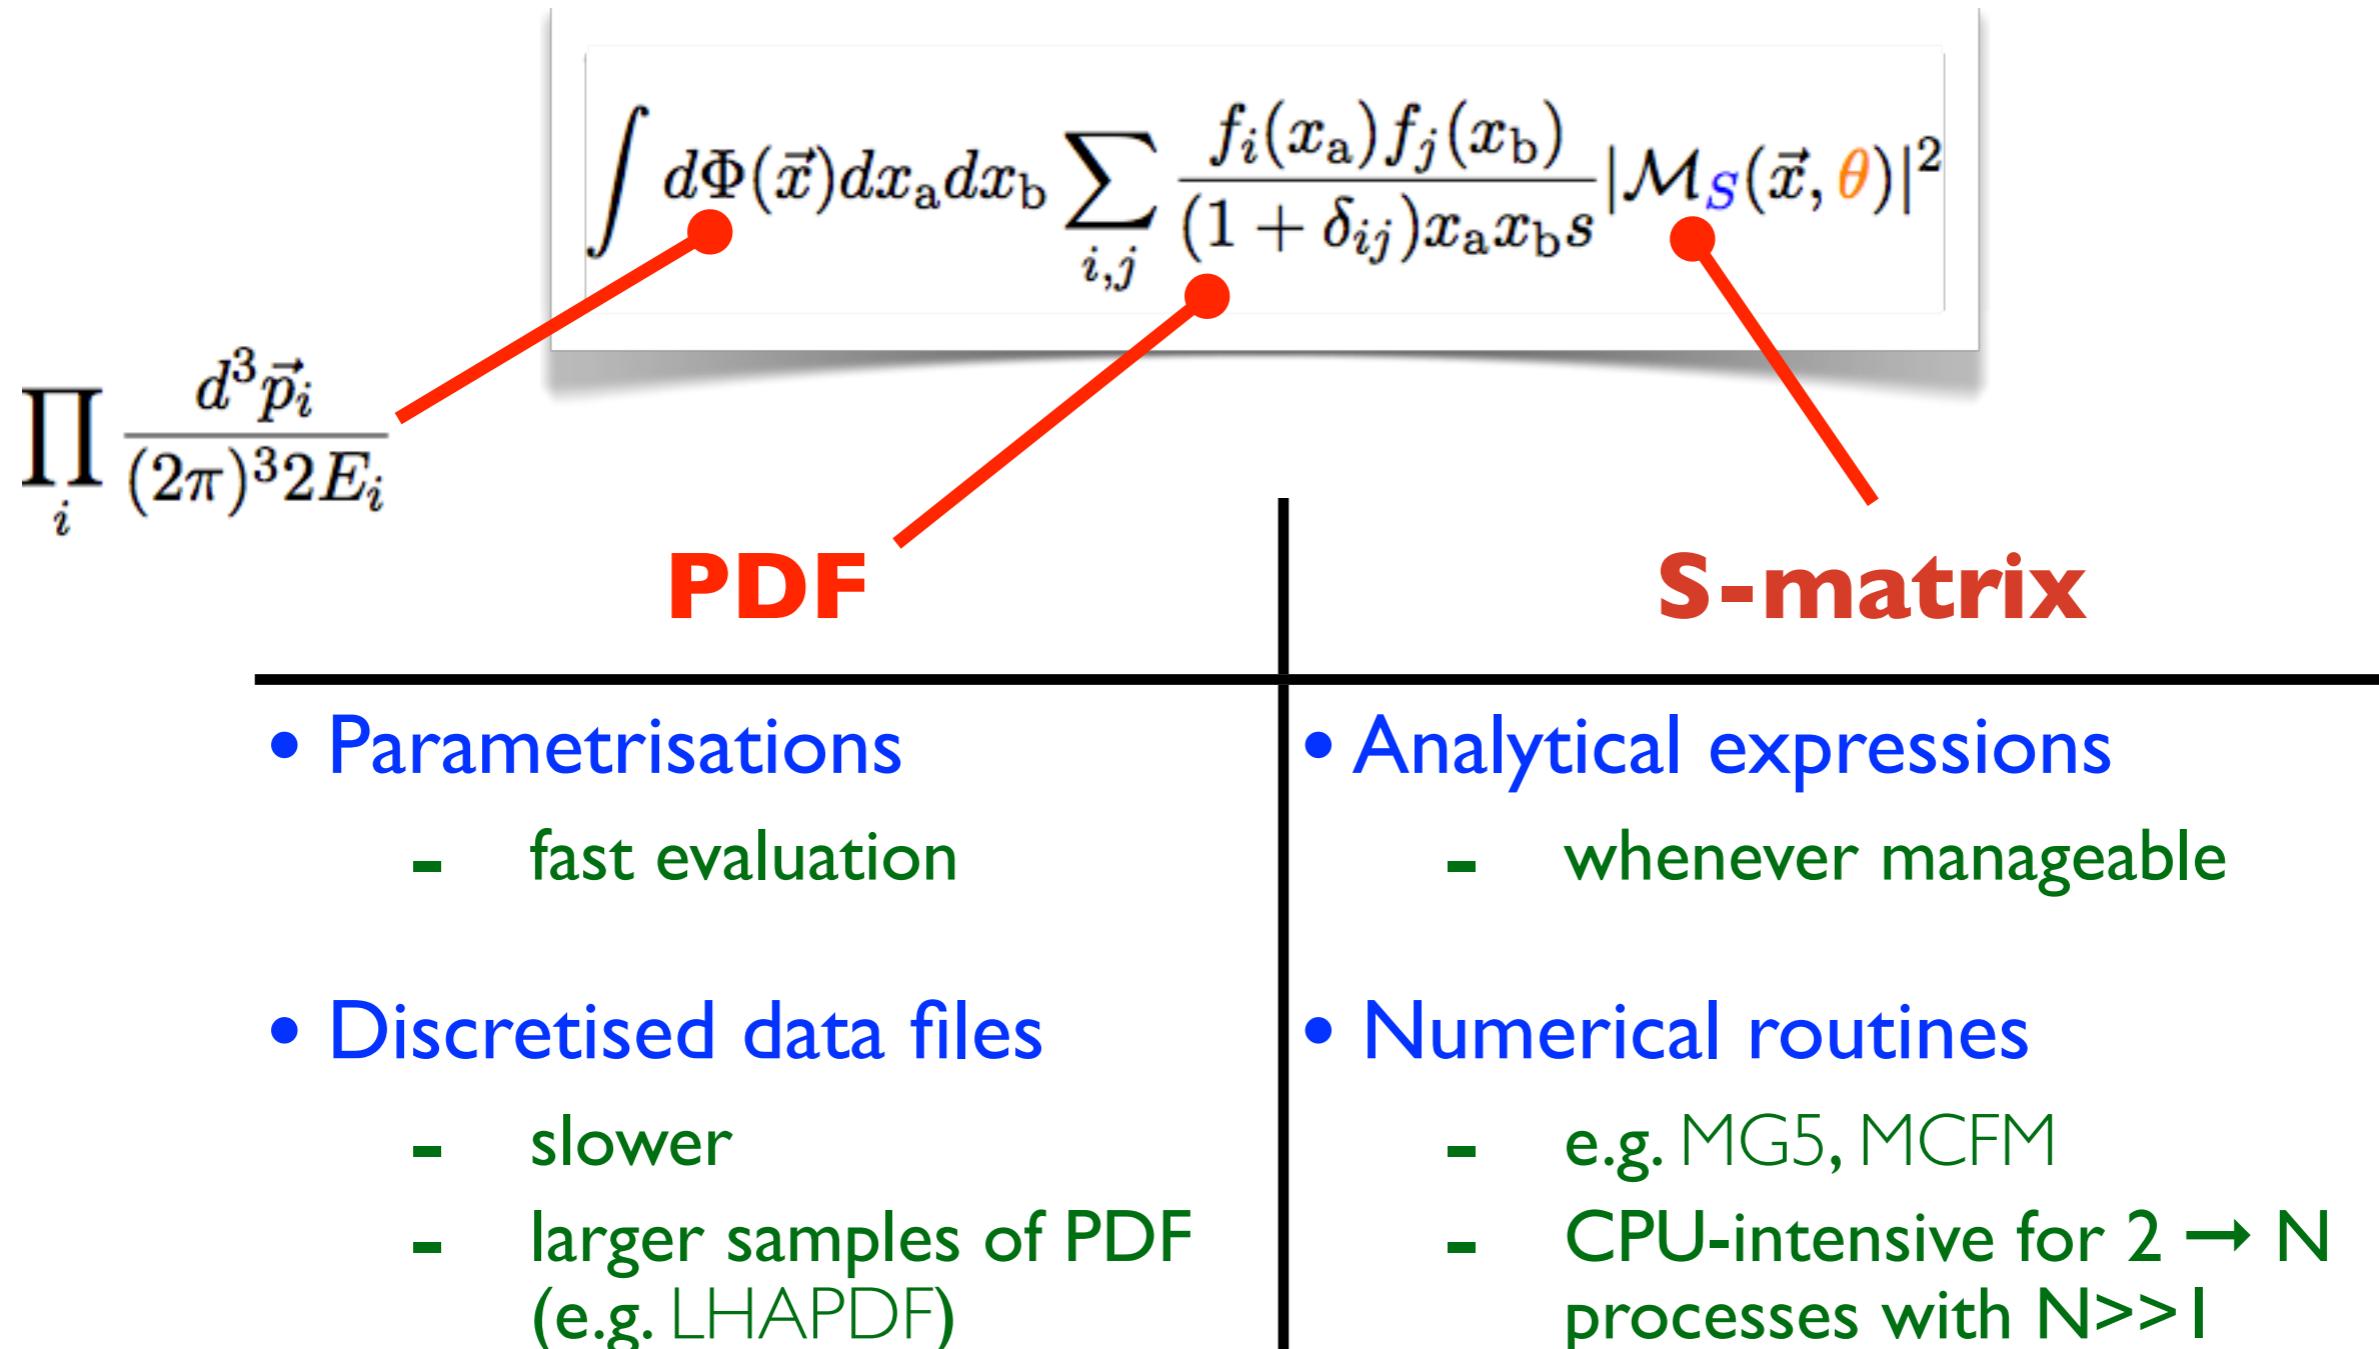

- ▶ assuming  $P_T$  balance in real events can be inefficient and/or biasing
- ▶ heuristic approaches based on
  - simple boost, Sudakov reweighting,  $p_T$  priors

# The integral

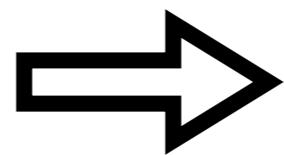

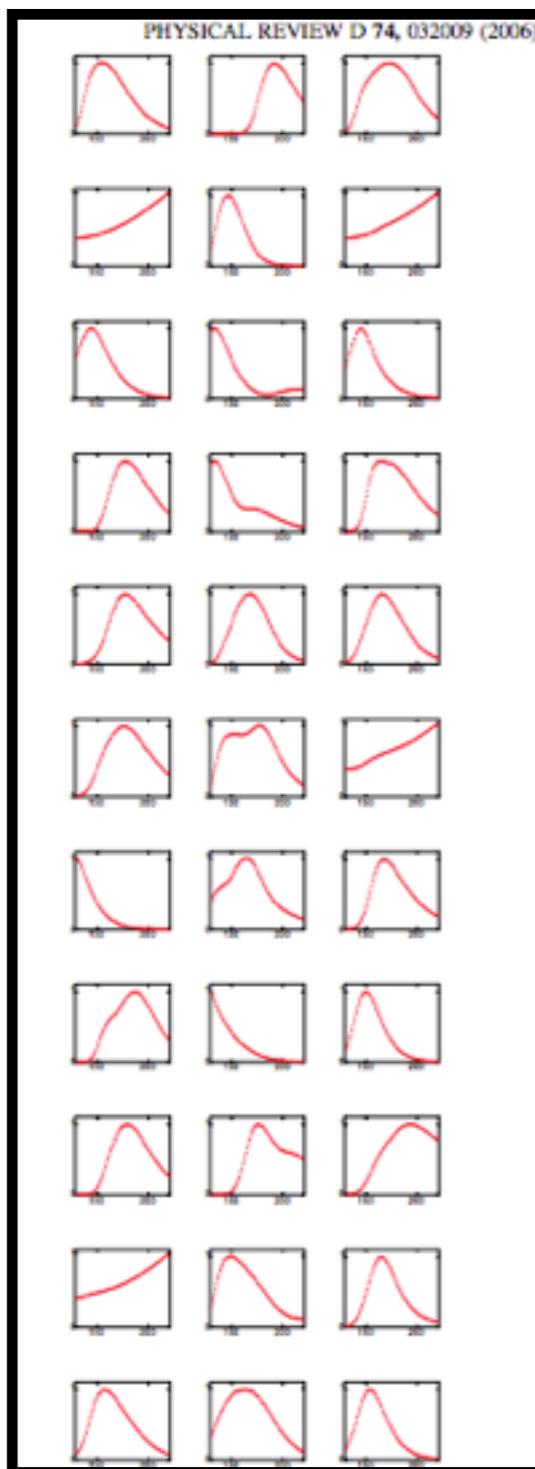

Calculation of  $d\sigma$  requires multi-dimensional integral

- ▶ numerical integration through MC methods
  - integrand often rapidly changing  $\Leftrightarrow$  adaptive MC's (e.g. VEGAS)

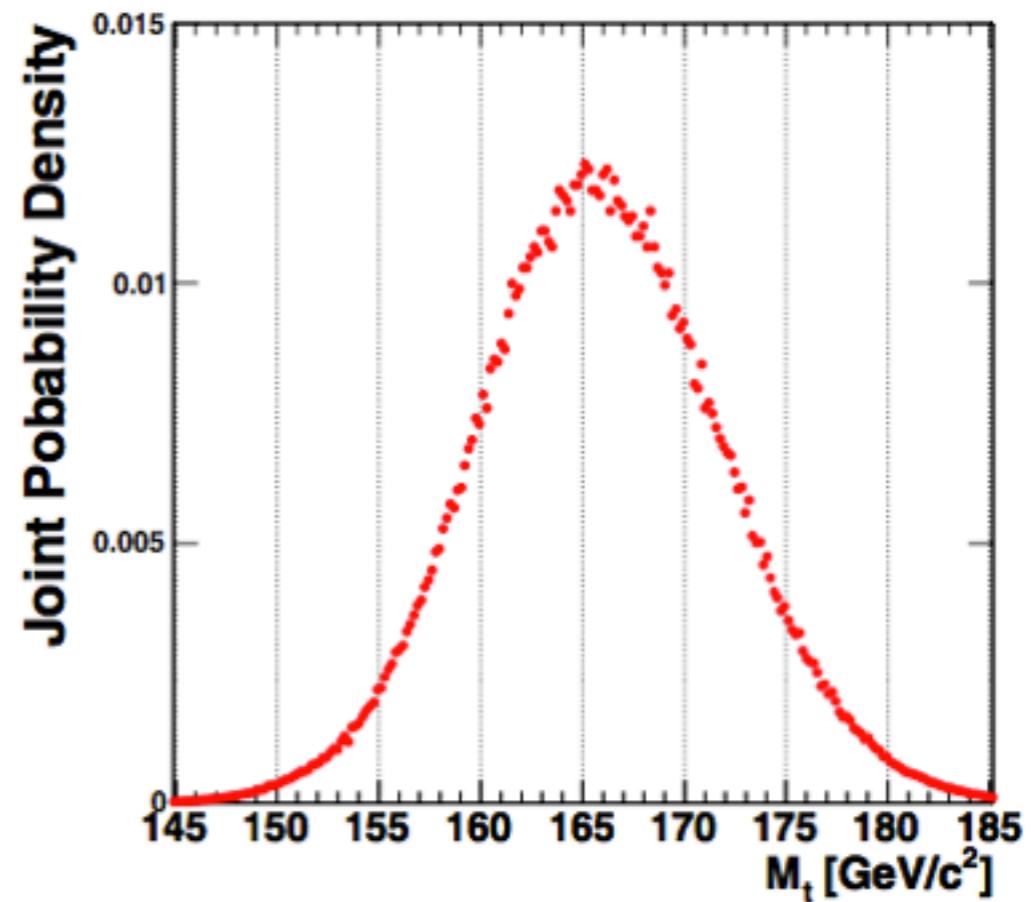

# Sample likelihood

**Event  
likelihoods:**

CDF, PRD 74, 032009 (2006)

**Sample likelihood:**

# Dimensional reduction

Calculation of  $p(y)$  requires multi-dimensional numerical integral

- ▶ reduce dimensionality using approximations
  - often a trade-off between CPU-cost and performances

- I. without ISR, initial partons have longitudinal momenta

$$d\Phi(\vec{x}) = (2\pi)^4 \delta(x_a P_a + x_b P_b - \sum_i p_i) \left[ \prod_i \frac{d^3 \vec{p}_i}{(2\pi)^3 2E_i} \right]$$

**2 initial partons ( $x_a, x_b$ )**      +      **N final-state particles**

→

$P_{x,y} = 0$

$x_{a,b} = \frac{E \pm P_z}{\sqrt{s}}$

**3N-2 variables**

2. narrow-width approximation

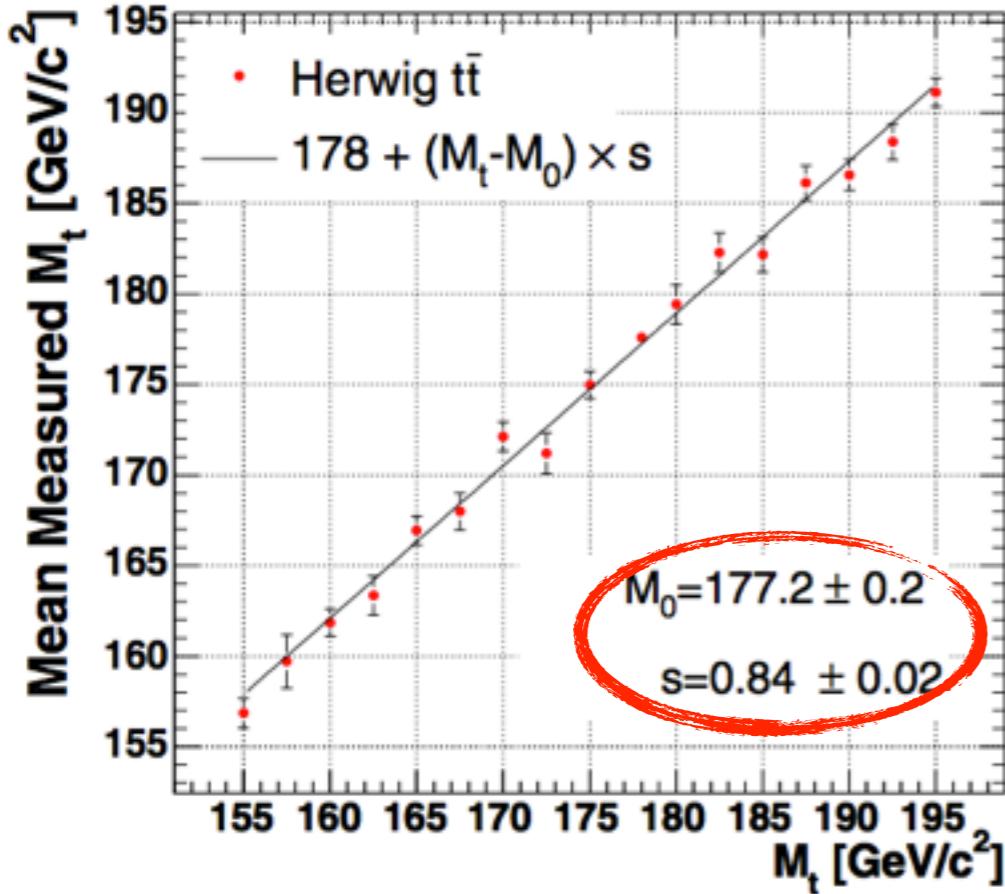

$$\frac{1}{(s^2 - M^2)^2 + \Gamma^2 M^2} \rightarrow \frac{\pi}{M\Gamma} \delta(s^2 - M^2)$$

# Systematics and bias

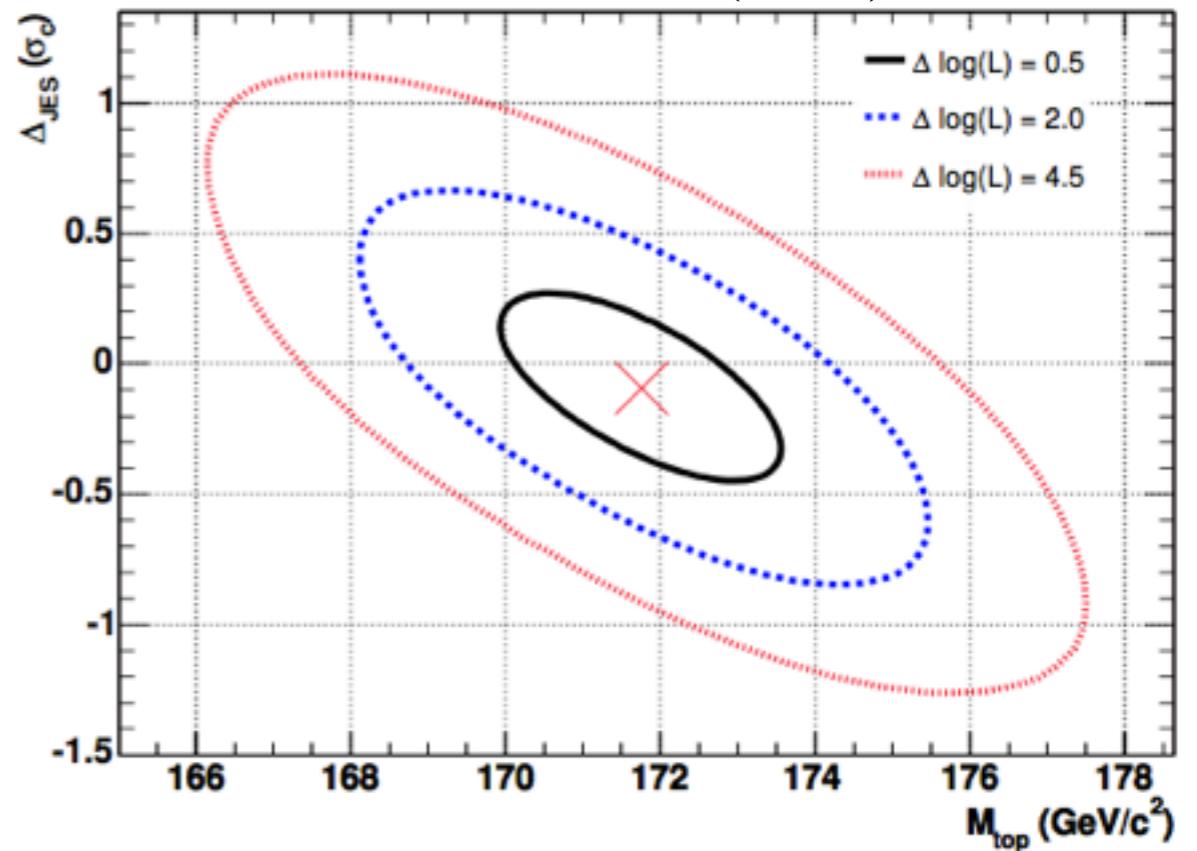

## Systematic uncertainties:

- ▶ included as nuisance parameters
- ▶ calculated event-by-event
  - each event contributes with optimal weight

CDF, PRD 74, 032009 (2006)

CDF, PRD 79, 092005 (2009)

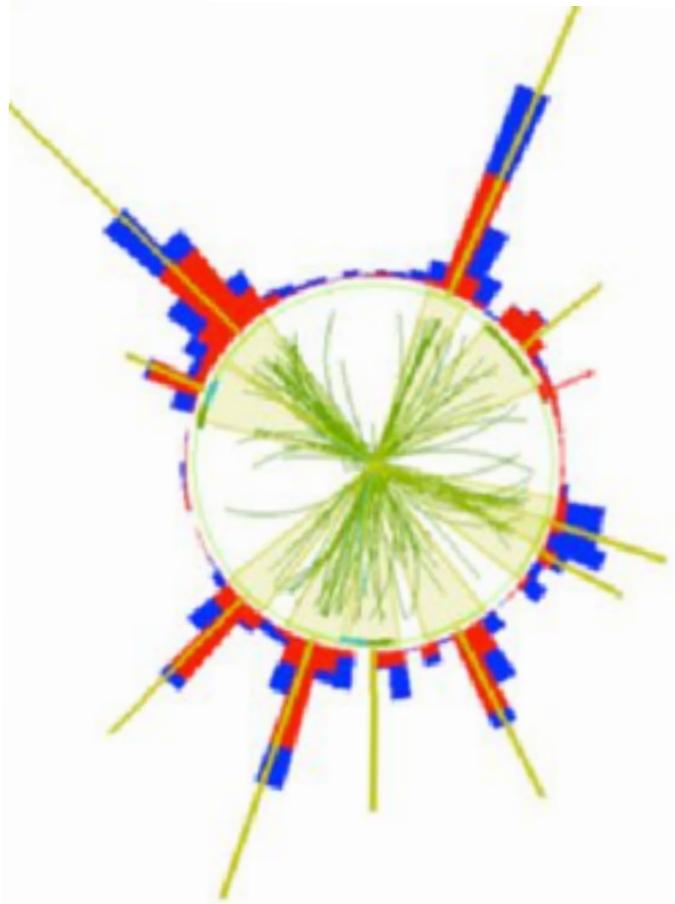

## Bias:

- ▶ approximations (underlying model, detector simulation)
- ▶ MC calibration requires
  - approximations in MEM don't hamper its applicability, just make it less optimal

# Jet/quark association

Jet  $\Leftrightarrow$  quark ambiguity  $\Rightarrow$  multiple associations

- ▶ growing as the factorial of the jet multiplicity
- ▶ ambiguity can be reduced by
  - jet  $\Leftrightarrow$  flavour assignment (e.g. b-tagging)
  - quark-exchange symmetry
- ▶ ambiguity increased by ISR/FSR and acceptance

# of jets (4 tags)	DL	# reco's light-quarks				
		$N_q = 0$	$N_q = 1$	$N_q = 2$	$N_q = 3$	$N_q = 4$
	$J = 4$	12	–	–	–	–
	$J = 5$	12	12	–	–	–
	$J = 6$	12	24	12	–	–
	$J = 7$	12	36	36	36	–
	$J = 8$	12	48	72	144	72

# Ideogram

$$\begin{aligned}\mathcal{L}_{\text{evt}}(x; m_t, \text{JES}, f_{\text{top}}) = & f_{\text{top}} \cdot P_{\text{sgn}}(x; m_t, \text{JES}) \\ & + (1 - f_{\text{top}}) \cdot P_{\text{bkg}}(x; \text{JES}) .\end{aligned}\quad (4)$$
