

# Simplified Cross Section Framework

Frank Tackmann

Deutsches Elektronen-Synchrotron

Higgs XS WG fiducial kick-off  
June 24, 2015

From Les Houches discussions with  
Josh Bendavid, Andre David, Marco Delmastro,  
Michael Duehrssen, Paolo Francavilla,  
Sabine Kraml, Michael Rauch, Kerstin Tackmann,

...

# Measurement vs. Interpretation.

Measurement

*theory-independent*

Interpretation

*theory-dependent*

where “Theory dependence” includes 2 aspects

- Dependence on underlying physics model:
  - ▶ Assume/test a specific model (Lagrangian)
  - ▶ Dependence on kinematic distributions
- Dependence on theory systematics/uncertainties
  - ▶ In theory predictions that are needed to extrapolate to total cross sections
  - ▶ Perturbative and parametric (PDFs,  $\alpha_s$ , ...)

# Pros and Cons of $\mu$ Fits.

Raw measurements

Direct theory dependence

Interpretation

## Pros

- Maximum possible sensitivity
- Allows use of advanced techniques like MVAs
- Can benefit from kinematic correlations among production modes across channels in combination

## Cons

- Theory predictions and *uncertainties* maximally entangled in results
- Any nontrivial theory changes require new results from experiments

## Pros

- Allows maximally theory-independent measurements
  - Results remain long-term useful
- ⇒ The ultimate goal ...

## Cons: Inevitably lose some sensitivity

- (Currently) only possible for cleanest channels:  $H \rightarrow \gamma\gamma, ZZ$
- Requires signal definitions such that experimental efficiencies are (close to) production-mode independent
  - ▶ E.g.  $H \rightarrow \gamma\gamma$  isolation included in signal definition, since isolation efficiency very different for  $t\bar{t}H$
  - ▶ Cannot use MVAs for signal selection
  - ▶ Sometimes simply not possible
- Projection onto several 1D spectra loses information compared to fully-differential level

# Split In the Middle.

## Ultimate Goals: Interface to split “Measurement” from “Interpretations”

- Minimize theory systematics in measurements
  - ▶ Clearer and systematically improvable treatment at interpretation level
- Measurements stay long-term useful
- Decouples measurements from discussions about specific models
- Allows for interpretation with different model assumptions/BSM scenarios
  - ▶  $\mu_i, \kappa_i$ , effective couplings, EFT coefficients, specific models

# Definition of Simplified Cross Sections.

Current  $\mu$  fits:

$$\begin{aligned}\sigma_1^{\text{meas}} &= A_1^{ggH} \times \underbrace{\mu_{ggH} \times \sigma_{ggH}^{\text{SM}}}_{\sigma_{ggH}} + A_1^{\text{VBF}} \times \underbrace{\mu_{\text{VBF}} \times \sigma_{\text{VBF}}^{\text{SM}}}_{\sigma_{\text{VBF}}} \\ &= A_1^{ggH} \times \sigma_{ggH} + A_1^{\text{VBF}} \times \sigma_{\text{VBF}}\end{aligned}$$

$$\begin{aligned}\sigma_2^{\text{meas}} &= A_2^{ggH} \times \underbrace{\mu_{ggH} \times \sigma_{ggH}^{\text{SM}}}_{\sigma_{ggH}} + A_2^{\text{VBF}} \times \underbrace{\mu_{\text{VBF}} \times \sigma_{\text{VBF}}^{\text{SM}}}_{\sigma_{\text{VBF}}} \\ &= A_2^{ggH} \times \sigma_{ggH} + A_2^{\text{VBF}} \times \sigma_{\text{VBF}}\end{aligned}$$

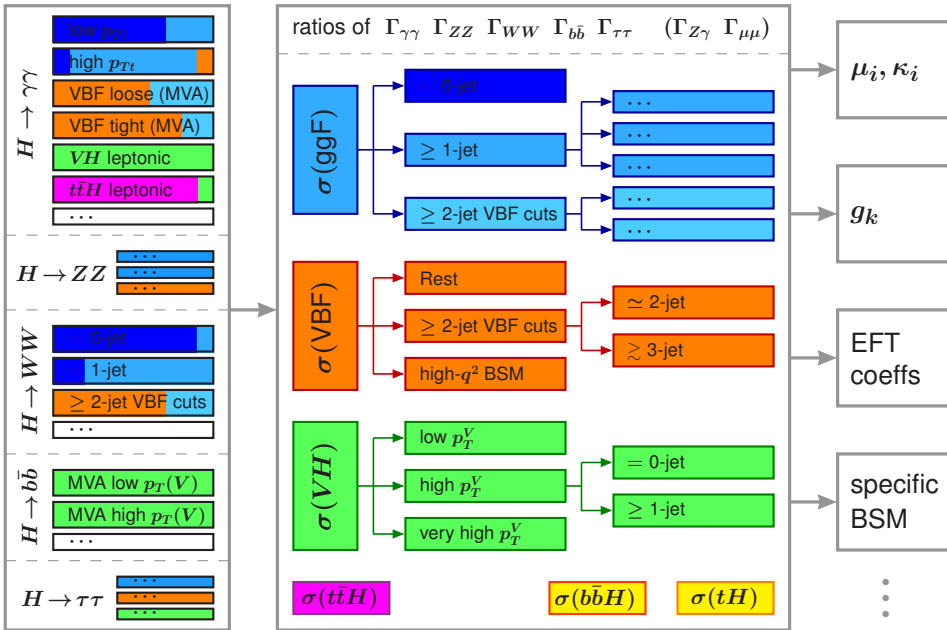

- Fit for  $\sigma_{ggH}$ ,  $\sigma_{\text{VBF}}$ 
  - ▶ In the SM: Correspond to total  $ggH$  and  $\text{VBF}$  production cross sections
- $A_i^{ggH}$ ,  $A_i^{\text{VBF}}$  are acceptances for SM processes  $\rightarrow$  theory-dependent
  - ▶ Split each production cross section into several kinematic bins/slices  $a$ ,  $b$ , ...

$$\begin{aligned}\sigma_1^{\text{meas}} &= A_1^{ggH a} \times \sigma_{ggH a} + A_1^{ggH b} \times \sigma_{ggH b} + A_2^{\text{VBF} c} \times \sigma_{\text{VBF} c} + \dots \\ \sigma_2^{\text{meas}} &= \dots\end{aligned}$$

- ▶  $A_i^j$  only depend on SM kinematics *inside* a given bin
- ▶ If this becomes a problem, split the bin

$\Rightarrow$  SM processes act as kinematic templates

# Simplified Cross Section Framework.

# Trying to Get the Best of Both Worlds.

## Difference compared to current $\mu$ fits

- Further split production modes into kinematic bins
- Fit for cross sections instead of  $\mu_i$

## Difference compared to fully-fiducial cross sections

- Non-Higgs backgrounds are subtracted
- Inclusive over the Higgs decays
  - ▶ Can perform a global combination of channels
- “Simplified” bin definitions *per production mode* abstracted from the actual measurement categories
  - ▶ Analyses can use optimized selections at reconstruction/analysis level
  - ▶ Can still use MVAs
  - ▶ Different production modes can have different efficiencies/acceptances without incurring dependence on SM production mode mix

⇒ Maximize sensitivity while reducing theory dependence

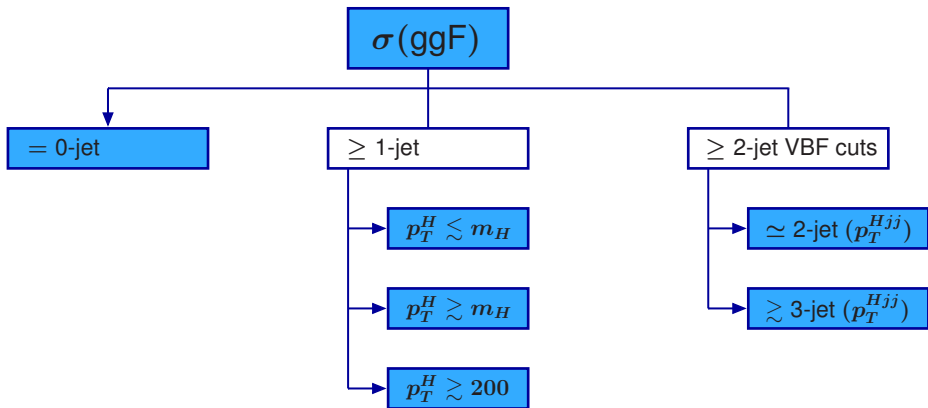

# Basic Design Principles.

- Bins should be reasonably well constrained (except BSM “overflow” bins)
- Identify phase-space regions that are most important to separate out from the theory side
  - ▶ Where are largest theory systematics (e.g. ggF 0jet bin)
  - ▶ BSM sensitivity/interpretation
- Try to minimize residual theory dependence
  - ▶ Try to align cuts with experimental categories to reduce extrapolations (e.g. reason to use  $p_T^V$  instead of  $m(VH)$ )
  - ▶ Still have to keep MVAs in check to avoid uncontrolled theory systematics
- Some of the observables might also be
  - ▶ Asymmetries
  - ▶ Continuous parameters for kinematic deviations (e.g. CP odd admixture)
- Definition of bins can evolve
  - ▶ Can split into more fine-grained bins as required and allowed by statistics (previous determinations remain useful)

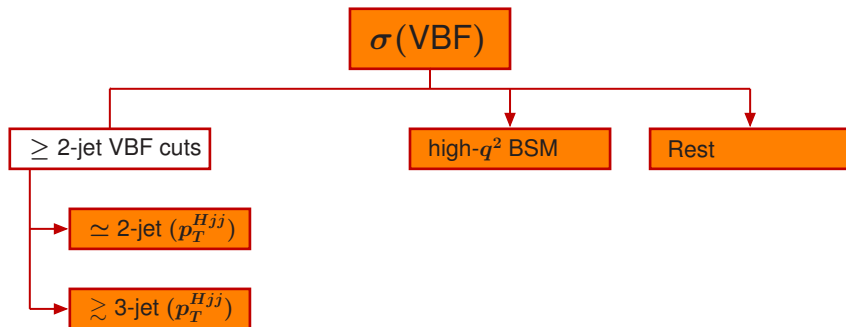

## In the following: Concrete proposal which came out of Les Houches

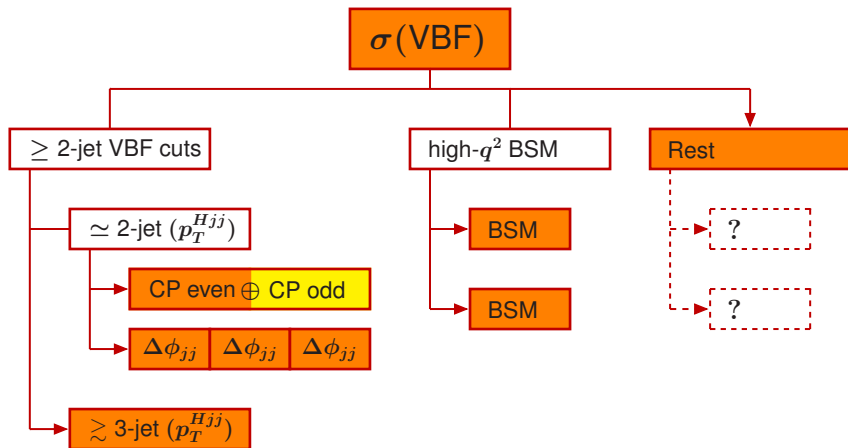

- Tries to balance minimal requirements for theory uncertainties and BSM sensitivity with experimental feasibility
- Define two scenarios
  - ▶ “Small” :  $\sim$  current statistics
  - ▶ “Medium”: medium-term, somewhere between now and 300/fb
- Specific details are not fixed
  - ▶ Feedback and ideas are very welcome
- Bins on each branch are by definition mutually exclusive and sum up to parent bin

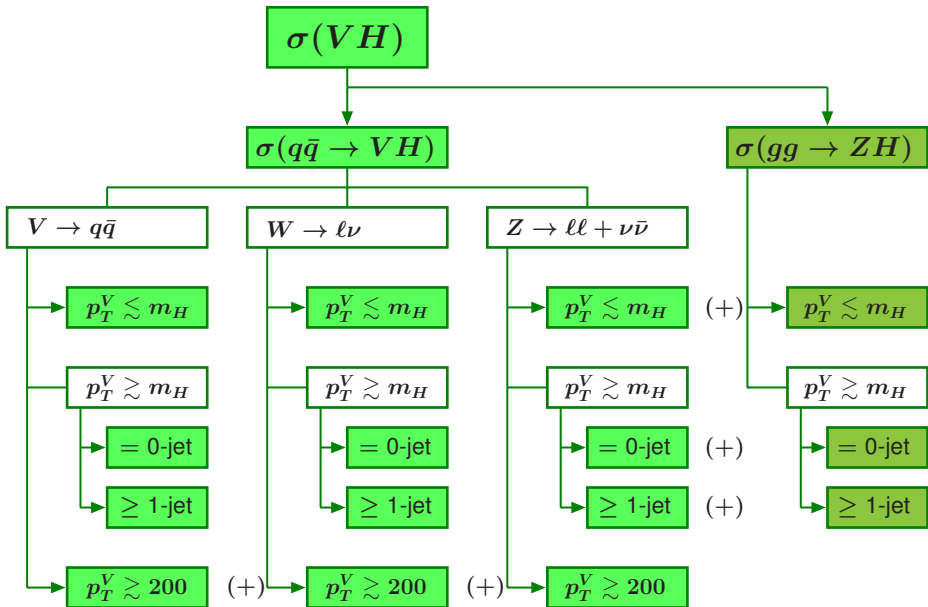

# $gg \rightarrow H$ : Medium-Term.

- Instead or in addition to binning in  $\Delta\phi_{jj}$  can use continuous parameter to allow for a CP-odd admixture

# $q\bar{q} \rightarrow VH$ : Medium-Term (similarly for $gg \rightarrow ZH$ ).

# Other Production Channels: Medium-Term.

- With enough statistics can start adding other production channels

## Finalize bin definitions

- Identify where kinematic bins and where continuous parameters or deformations are better suited
- Input from BSM community important

## Treatment of decays

- Currently use (ratios of) partial widths  $\Gamma_{\gamma\gamma}$ ,  $\Gamma_{ZZ}$ ,  $\Gamma_{WW}$ ,  $\Gamma_{b\bar{b}}$ ,  $\Gamma_{\tau\tau}$ , ...
- Can extend these with decay POs ( $\rightarrow$  see Gino's talk)

## Precise definition of $\sigma(ggF)$ , $\sigma(VBF)$ , $\sigma(VH)$ , ...

- Basic idea: Want SM process to act as kinematic template (treat SM itself like a “simplified model”)
  - ▶ Experimental: Use corresponding SM MC samples
  - ▶ Theoretically: Need to be well-defined such that theorists know precisely what to calculate (at least in the SM limit)
- How to best quantify residual dependence on SM distribution inside each bin

## The Proposal

- is that this will be the evolution of combined  $\mu$  measurements
  - ▶ ... can still do  $\mu$  fits with these as input layer (just like any other interpretations like EFT)
- Experiments would publish results for combined and/or channel-specific simplified cross sections
  - ▶ ... including full covariance (or if insufficient full likelihood)

## This *does not*

- replace full-fledged fiducial cross section measurements
  - ▶ ... but converges toward them in high statistics limit
- exclude optimized analyses for specific purposes (e.g. spin or CP measurements, dedicated BSM searches)

## Next Steps

- Dedicated WG2 meeting 1st week of July (see your inbox for a doodle)
- Planning to have a joint writeup for YR4 and Les Houches proceedings
