

Jet Quenching

Ivan Vitev

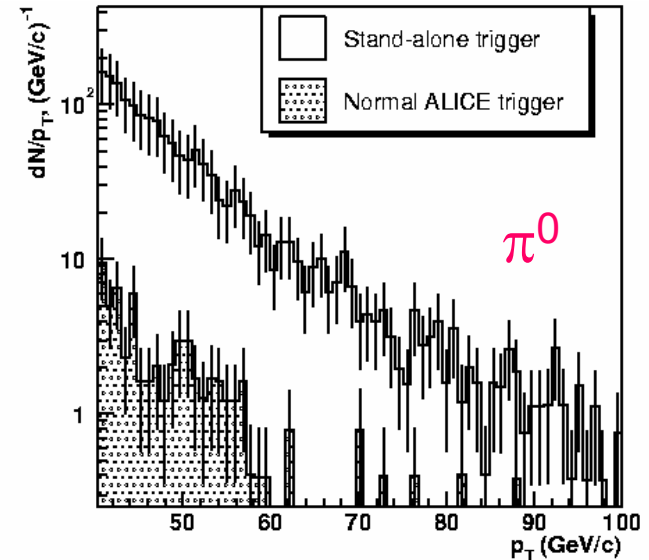

Heavy Ion Physics at the LHC, PANIC 2005
Santa Fe, NM

ALICE at High p_T

A.Dainese, ALICE talk

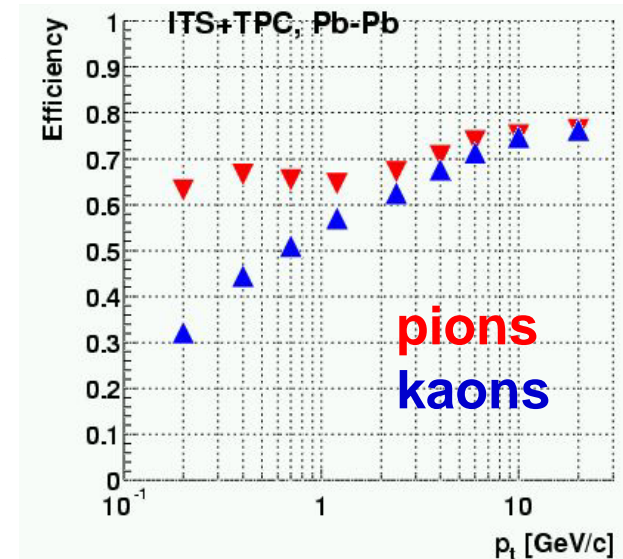

1 year ALICE: $\sim 10^3$ $p_t > 50$ GeV

Identified particles: D^0 to 15 GeV

Λ to 12 GeV, γ/π^0 to 100 GeV

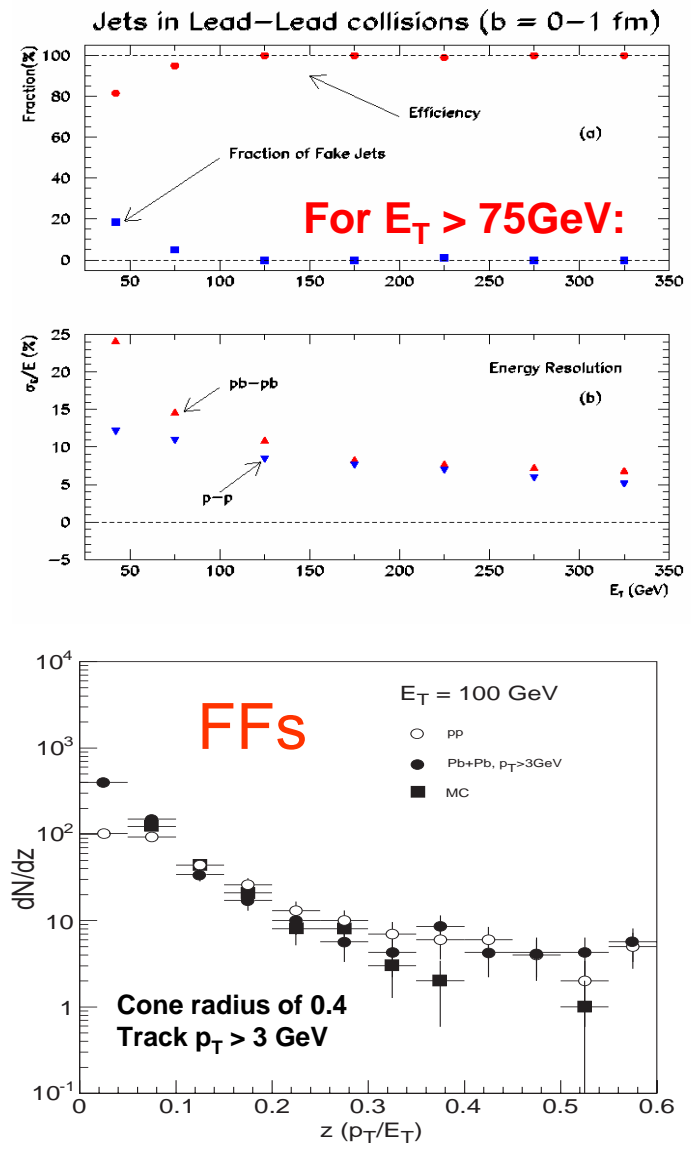

Tracking capabilities
for low $p_T < 1$ GeV

Particle ID

ATLAS for Heavy Ions

L.Rosselet, ATLAS talk

- Hermetic calorimeter $|\eta| < 4.9$
- $\Delta\eta\Delta\Phi = 0.025 \times 0.025$ (e.g.) EM; 0.1×0.1 Hadronic
- Large acceptance μ -spectrometer $|\eta| < 2.7$
- Silicon Tracker $|\eta| < 2.5$
- Finely segmented pixel and strip detector (SCT)
- Good resolution $p_T \geq 0.5$ GeV

CMS for Heavy Ions

C.Roland, CMS talk

Silicon Tracker

Excellent momentum resolution $\Delta p/p \sim 1\%$

Fine Grained High Resolution Calorimeter (E-cal+H-cal)

Hermetic coverage up to $|\eta| < 5$

Muon Reconstruction

Tracking μ from $Z^0, J/\psi, \Upsilon$
Wide rapidity range $|\eta| < 2.5$

1000 Pb Pb Events @ LHC:

100GeV Jet in a Pb+Pb event (after background subtraction)

Theoretical Input (Outline)

- **Single inclusive particle quenching at high p_T :**

→ **Careful implementation of valid e-loss approaches. Centrality and particle species dependence. Heavy flavor energy loss**

Light mesons π^0 to 100 GeV (ALICE), Baryons to 10 – 15 GeV? (ALICE)
Heavy flavor D-mesons to 15 GeV (ALICE)

- **Tagged γ , Z^0 inclusive (multi) hadrons:**

→ **Realistic differential calculations of double differential gluon distribution. Integration in jet shape formalisms. Redistribution of the energy.**

Above few GeV (“FFs”) (ATLAS) Particle distributions in the jets
 $k_T > 1$ GeV (CMS)

- **High E_T jets at $Y = 0$ and $Y \neq 0$, jet correlations:**

→ **High E_T TeV jets, algorithm dependence, energy loss as a function of Y , jet correlations with large rapidity gaps**

Millions of > 200 GeV Jets (ATLAS, CMS). Large $|y| < 5$ coverage (ATLAS, CMS)

LHC Cross Sections

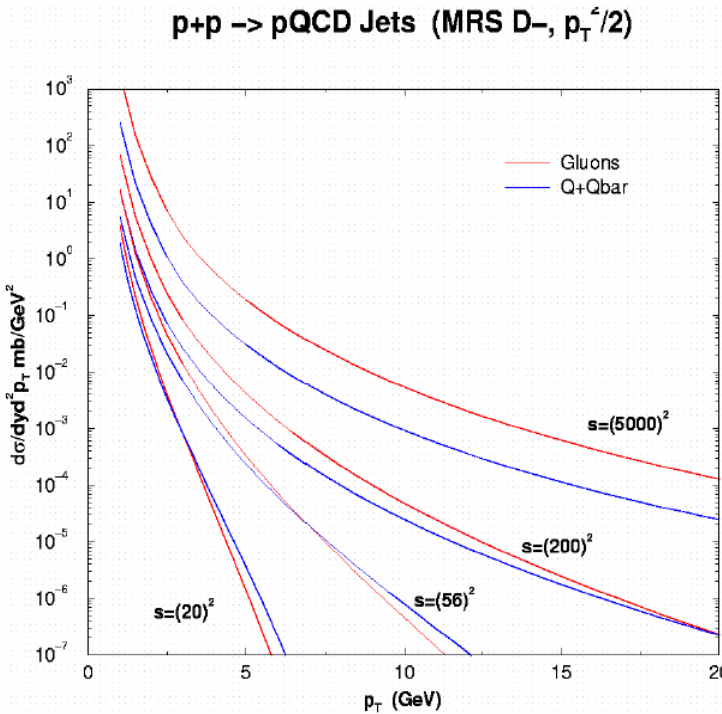

Unprecedented new capabilities for high p_T and jet physics

$p+p @ \sqrt{s} = 14 \text{ TeV}$

$p+A @ \sqrt{s} = 8.8 \text{ TeV}$

$A+A @ \sqrt{s} = 5.5 \text{ TeV}$

Baseline
problem?

A.Adil, M.Gyulassy

I.V., CERN Yellow Report

Orders in magnitude gain in both jet and inclusive particle cross sections

Low x and High p_T

Longitudinal size: $\sim 1/2m_N x$
 If $x < 0.1$ then $\Delta z > r_0$

Transverse size: $\sim 1/Q$
 If $Q < m_N$ then exceed the parton size

- Interactions will happen coherently but this does not mean that they don't have substructure – **at high p_T single hard scattering dominates**

Condition: $p_T^2 > \mu^2 L / \lambda, \xi^2 A^{1/3}, Q_s^2$

$$\frac{dW_h}{d^2 p_t}(x, b, \beta) = \Gamma_h(x, b - \beta) \sum_{\nu=1}^{\infty} \frac{1}{\nu!} \int \Gamma_A(x'_1, b) \dots \Gamma_A(x'_\nu, b) e^{-\int dx' \Gamma_A(x', b) \sigma(xx')}$$

$$\times \frac{d\sigma}{d^2 k_1} \dots \frac{d\sigma}{d^2 k_\nu} \delta^{(2)}(\mathbf{k}_1 + \dots + \mathbf{k}_\nu - \mathbf{p}_t) d^2 k_1 \dots d^2 k_\nu dx'_1 \dots dx'_\nu$$

$$\langle p_t^2(x, b) \rangle_A \sim \begin{cases} \langle p_t^2(x, b) \rangle_1 & \text{as } p_0 \rightarrow \infty \\ \langle p_t^2(x, b) \rangle_1 \langle n_A(x, b) \rangle & \text{as } p_0 \rightarrow 0 \end{cases}$$

A. Accardi and D. Treleani, Phys.Rev.D 64 (2001)

$$\xi^2 = 0.1 - 0.2 \text{ GeV}^2$$

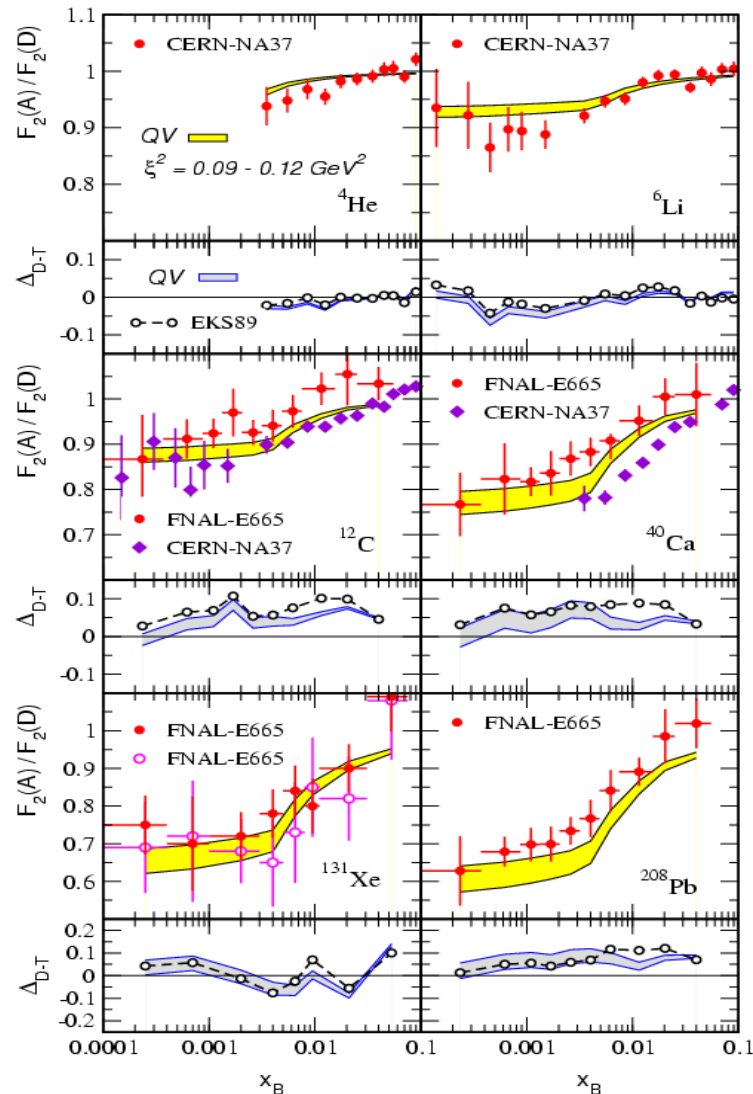

Coherent Power Corrections

Purely quantum effect

$$F_T^A(x, Q^2) \approx A F_T^{(LT)} \left(x + \frac{x\xi^2 (A^{1/3} - 1)}{Q^2}, Q^2 \right)$$

The scale of higher twist per nucleon is small $\xi^2 \approx 0.1 \text{ GeV}^2$

Beware of "improvements"

Medium Induced Radiation

Applicable for realistic systems

Study the convergence of the series: 2, 3, 4, ..., n, ...
body correlations

$$\Delta E^{(1)} \approx \frac{C_R \alpha_s}{4} \frac{\mu^2 L^2}{\lambda_g} \text{Log} \frac{2E}{\mu^2(L)L} + \dots,$$

- Static medium

$$\Delta E^{(1)} \approx \frac{9\pi C_R \alpha_s^3}{4} L \frac{1}{A_\perp} \frac{dN^g}{dy} \text{Log} \frac{2E}{\mu^2(L)L} + \dots,$$

- 1+1D Bjorken

	Static	RHIC, LHC

Transport coefficient

$$\hat{q} = \frac{\mu^2}{\lambda}$$

OK

Bad

Parton rapidity density

-

OK

$\mu(\text{RHIC}) = gT \sim 1 \text{ GeV}$	$\hat{q} = 4 - 14 \text{ GeV}^2 / \text{fm}$	$\lambda = 0.25 - 0.07 \text{ fm}$
$\mu(\text{LHC}) = gT \sim 2 \text{ GeV}$	$\hat{q} = 30 - 100 \text{ GeV}^2 / \text{fm}$	$\lambda = 0.125 - 0.04 \text{ fm}$

$$\Delta E^{(1)} \propto \frac{C_R \alpha_s}{2} \left(\frac{\mu^2}{\lambda} \right)_0 \tau_0 L \dots$$

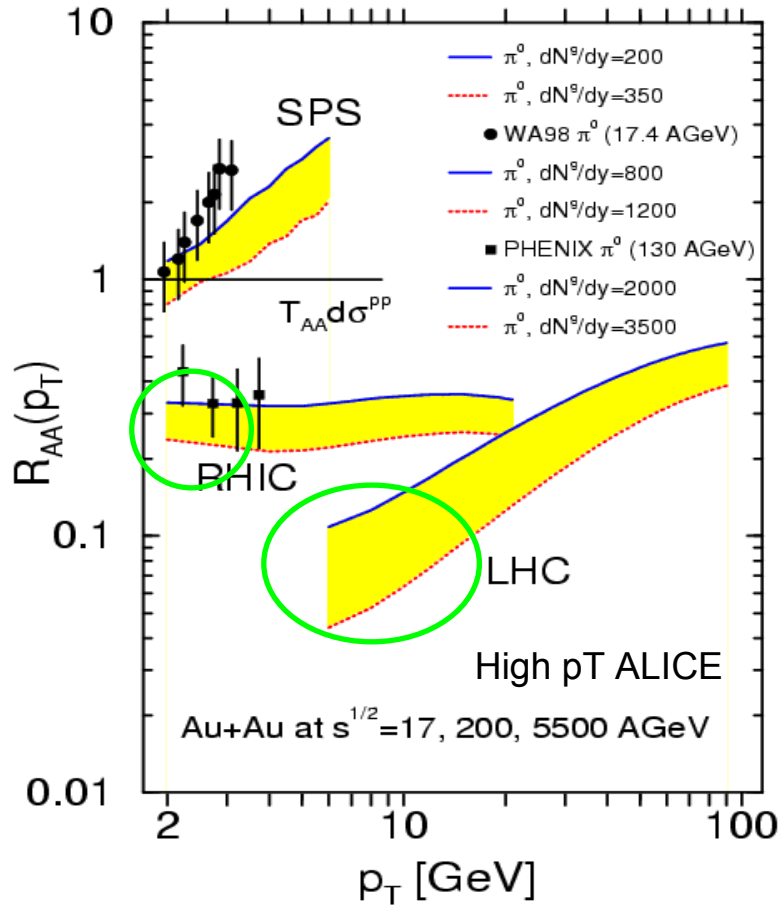

The constraint (all approaches):

Inconsistent with large number of scatterings approximation

$$\sim e^{-\lambda \mu}$$

Single Inclusive Quenching

I.V., M.Gyulassy, Phys.Rev.Lett. 89 (2002)

- Room for improvement at small and moderate p_T

$$\rho = \frac{1}{\pi R^2} \frac{1}{\tau_0} \frac{dN^s}{dy}, \quad \pi R^2 = 120 \text{ fm}^2, \quad \tau_0 = 0.5 \text{ fm}$$

RHIC 20 times $e=E/V$ for deconfinement

LHC 200 times $e=E/V$ for deconfinement

See also Wang et al., Paic et al., Eskola et al., Gale et al. ...

Coexistence RHIC II and LHC

Very important to be tested – establish the role of kinematics versus dynamics

- The density dN^g/dy at the LHC is assumed 2-3 times larger

$$\Delta E \propto dN^g / dy \text{ Bjorken}$$

- This p_T range is dominated by gluons, not quarks, at the LHC

$$\Delta E \propto C_A = 3 \text{ gluons, } C_F = 4/3 \text{ quarks}$$

(analog to el. charge squared)

In spite of these factors in the 30-40 GeV range the suppression at RHIC increases - comparable or larger than at the LHC

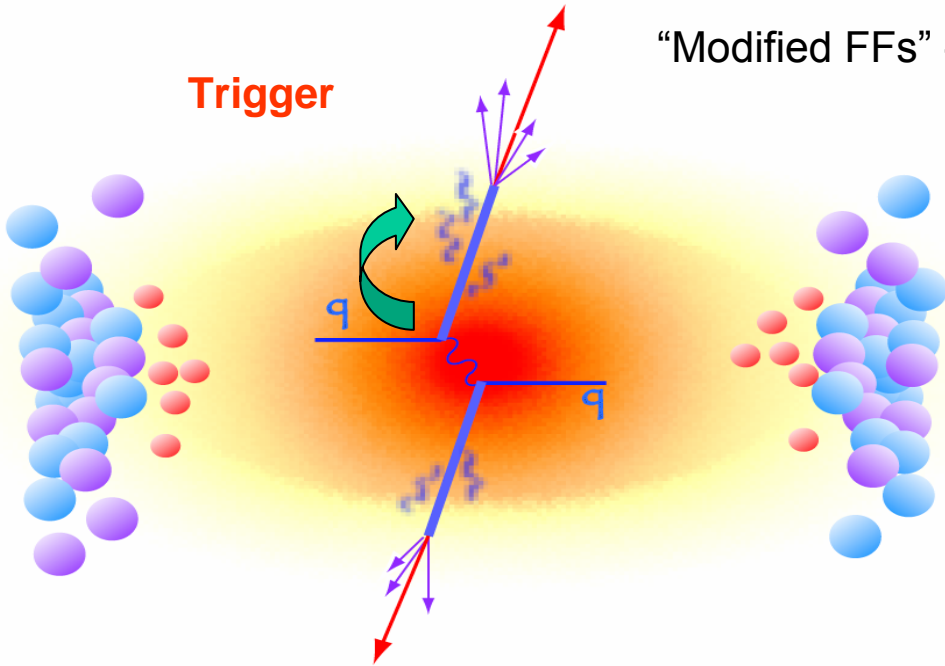

Can be **only** achieved only through comparison of similar quenching under different physics conditions

(Di)Hadrons and Feedback Energy

“Modified FFs” - **misconception**

- Not universal
- Kinematic redistribution of E

$$p_c \rightarrow p_c(1 - \epsilon), \quad z_c \rightarrow \frac{z_c}{(1 - \epsilon)}$$

$$p_c \rightarrow (\epsilon)p_c, \quad z_g \rightarrow \frac{z_c}{(\epsilon)}$$

$$D_{h_1/d}(z_1) \rightarrow \frac{1}{1 - \epsilon} D_{h_1/d} \left(\frac{z_1}{1 - \epsilon} \right)$$

Quenched parent parton

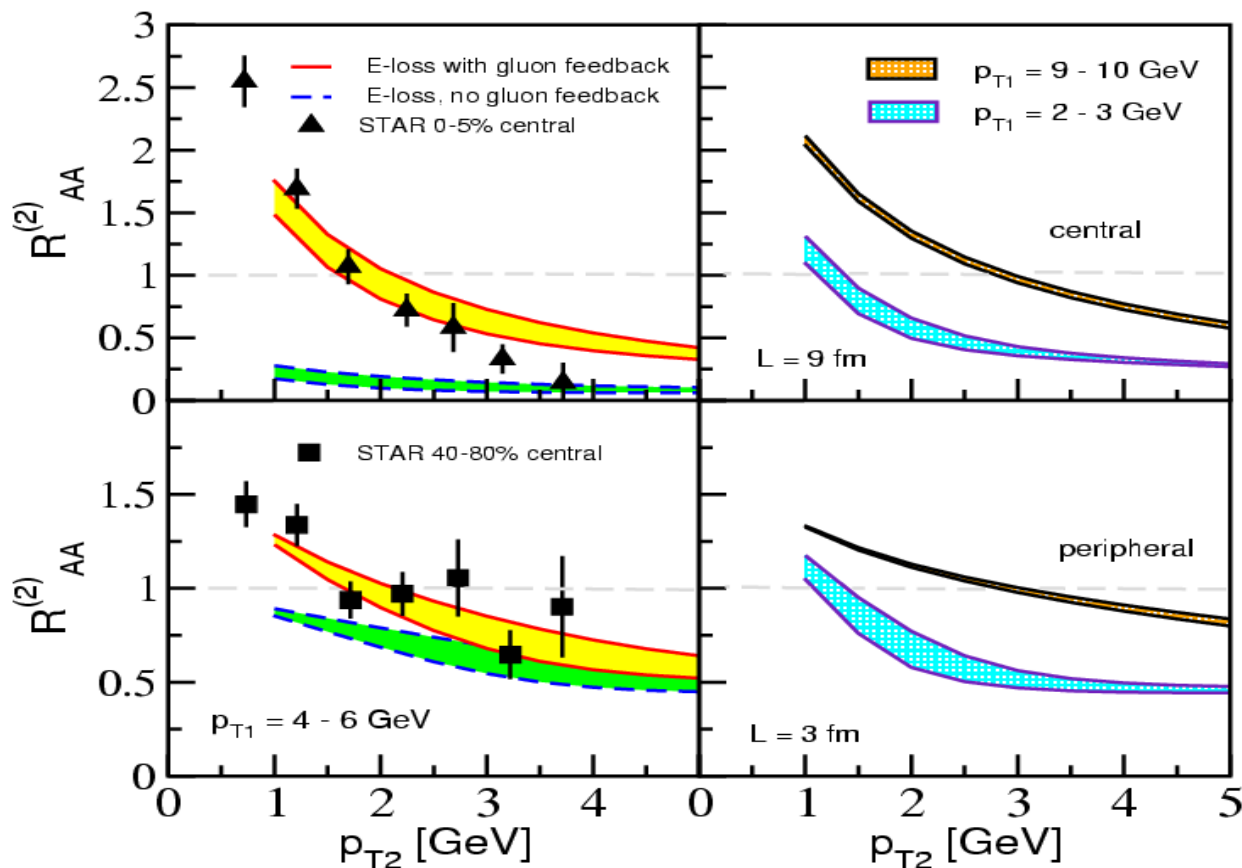

Feedback gluons

$$+ \frac{p_{T_1}}{z_1} \int_0^1 \frac{dz_g}{z_g} D_{h_1/d}(z_g) \frac{dN^g}{d\omega}$$

- Use **energy conservation** to verify the fragmentation sum rule

I.V., Phys.Lett.B in press, hep-ph/0501255

Example of E-Redistribution

Data is from:

J.Adams *et al.*, Phys.Rev.Lett.
in press, nucl-ex/0501016

Very interesting as
a function of trigger

Even more important
at the LHC

ALICE, ATLAS, CMS

- To be implemented in the single ineluctives (extend to lower p_T at the LHC)
- For tagged jets - **radiative** gluons to unexpectedly high p_T ("FFs")
- The angular distribution?

Angular Distribution

The physics is more interesting than a Brownian motion of the gluon

$$i(-i) = 1 \quad i(i) = -1 = \cos(\pi)$$

$$\frac{dN_{med}^g}{d\omega d\sin\theta^* d\delta} \propto (|M_a|^2 + 2\text{Re} M_b^* M_c) + \dots$$

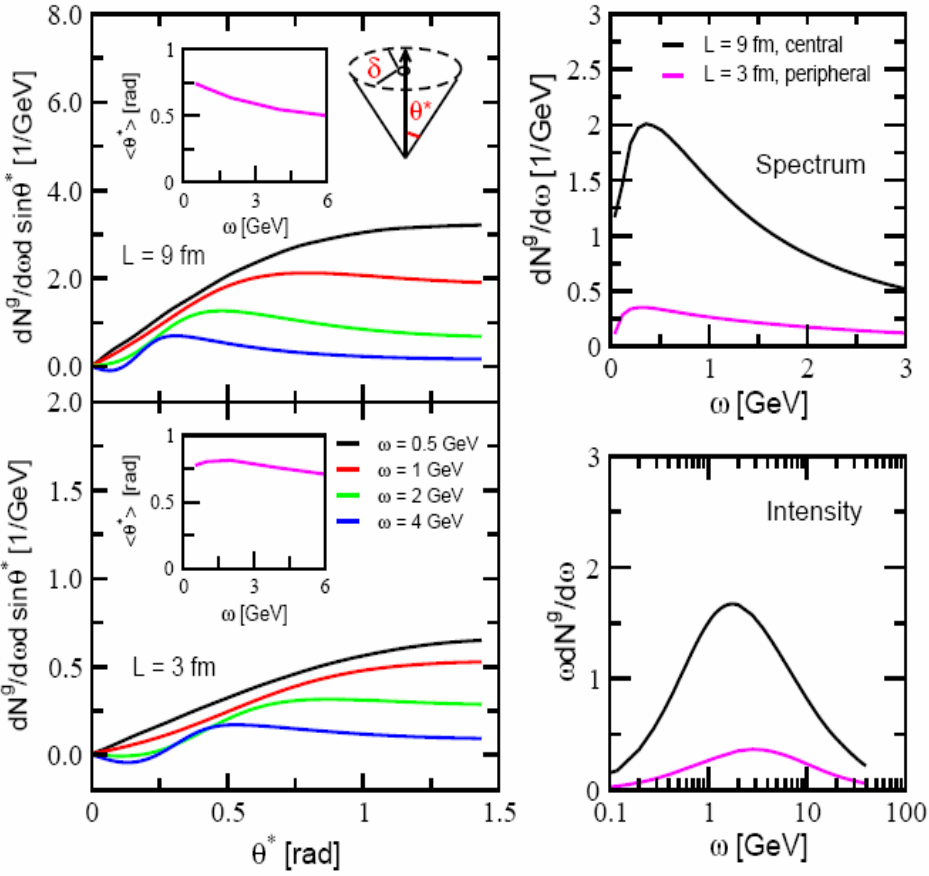

Solution to first order in the mean # of scatterings

$$\frac{dN_{med}^g}{d\omega d\sin\theta^* d\delta} \approx \frac{2C_R \alpha_s}{\pi^2} \int_{z_0}^L \frac{d\Delta z}{\lambda_g(z)} \int_0^\infty dq_\perp q_\perp^2 \frac{1}{\sigma_{el}} \frac{d\sigma_{el}}{d^2q_\perp} \times \int_0^{2\pi} d\alpha \frac{\cos\alpha}{(\omega^2 \sin^2\theta^* - 2q_\perp \omega \sin\theta^* \cos\alpha + q_\perp^2)} \times \left[1 - \cos \frac{(\omega^2 \sin^2\theta^* - 2q_\perp \omega \sin\theta^* \cos\alpha + q_\perp^2) \Delta z}{2\omega} \right]$$

I.V., Phys.Lett.B in press, hep-ph/0501255

Angular Distribution (Jet Cone)

- Radiation is **moderately large angle** (cancellation near the jet axis)
- **Finite** gluon number. E carried by few 0.5 – 5 GeV gluons 0.25 – 0.75 rad

Choices for opening angles (θ^*)

$$R = \sqrt{\Delta\eta^2 + \Delta\phi^2} = 0.4, 0.7, 1$$

- **Promising**
- **To be done for LHC kinematics**

• The small angle $\theta^* \rightarrow 0$ and small frequency $\omega \rightarrow 0$ behavior of the radiative spectrum is under perturbative control

Previous study found less than 10% effect

C.A.Salgado, U.Wiedemann
Phys.Rev.Lett. (93) 2004

Ivan Vitev, LANL

Mass Effects on E-Loss

Cutting out part of the available phase space

Note that the characteristic features of E-loss are related to the **interference phases (QM versus PS)**

$$\left[\omega_{(1\dots n)} \right]^{-1} \rightarrow \left[\omega_{(1\dots n)} + \frac{m_g^2 + x^2 M^2}{2xE} \right]^{-1}$$

$$\frac{\vec{k}_\perp}{\vec{k}_\perp^2} \rightarrow \frac{\vec{k}_\perp}{\vec{k}_\perp^2 + m_g^2 + x^2 M^2}, \quad x = \frac{k^+}{p^+} \approx \frac{\omega}{E}$$

“Dead cone”

Y.Dokshitzer, D.Kharzeev, Phys.Lett.B (2001)

Not a large contribution

Reduction of E-loss

M.Djordjevic, M.Gyulassy, Nucl.Phys.A (2004)

Heavy Quarks R_{AA}

M.Djordjevic, M.Gyulassy, R.Vogt, nucl-th/0507019

See also Armesto, et al.

The R_{AA} for **charm** can reach values of 1/4 but **bottom** is limited to 1/2
 One should be careful about the **physical meaning** of the parameters!

$dN^g / dy = 3500 \quad \hat{q} = 15 \text{ GeV}^2 / \text{fm}$

Where does one get such parameters from?

Are these leptons from heavy mesons? (Cocktail methods...) FVTX

What are the different attenuation mechanisms for heavy mesons?

Forward Y (Di)Jet Quenching

Very relevant to ATLAS and CMS

Baseline: $\frac{d\sigma}{dy d^2 p_T} = \frac{a}{(p_0 + p_T)^n} \approx \frac{a}{p_T^n}$

$\frac{\Delta E}{E} \propto \frac{L}{A_\perp} \frac{dN^s}{dy} \propto A^{2/3} \propto N_{part}^{2/3}$

Start from: $p_T + \Delta p_T$

$$R_{AA} = \frac{1}{\left(1 + \frac{\Delta p_T}{p_T}\right)^{n-2}} = \frac{1}{\left(1 + \kappa' N_{part}^{2/3}\right)^{n-2}}$$

A.Adil, M.Gyulassy, I.V. in preparation

T.Hirano, Y.Nara, Phys.Rev.C68 (2003)

E-Loss in Cold Nuclear Matter

A number of nuclear effects: Cronin, power corrections, energy loss

$$\frac{\omega dN_{med}^g}{d\omega d^2k_{\perp}} \approx \frac{C_A \alpha_s}{\pi^2} \left(\frac{L}{\lambda} \right) \left\langle \frac{q_{\perp}^2}{k_{\perp}^2 (k_{\perp} - q_{\perp})^2} \right\rangle_{q_{\perp}} \rightarrow \frac{C_A \alpha_s}{\pi^2} \left(\frac{L}{\lambda} \right) \frac{\mu^2}{k_{\perp}^2 (k_{\perp}^2 + q_{\perp}^2)}$$

$$\frac{\Delta E}{E} \propto \frac{C_A \alpha_s}{\pi} \left(\frac{L}{\lambda} \right) \ln \frac{\mu^2}{\Lambda^2}$$

Substantial: ? **not** "Are they sufficient"
"Why are they so small"

Parton splitting, not parton fusion

B.Z. Kopeliovich, J. Nemchik, I.K. Potashnikova, M.B. Johnson, I. Schmidt, hep-ph/0501260

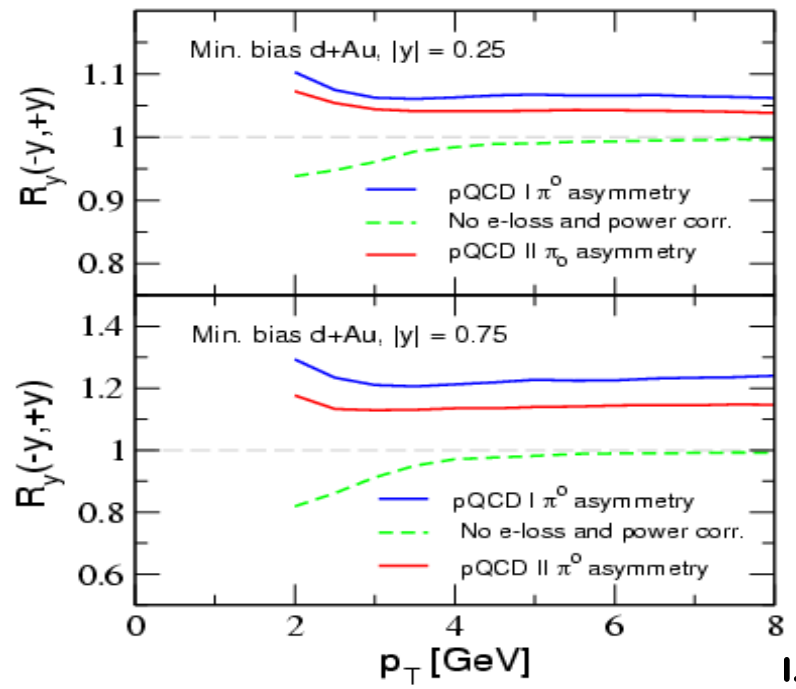

K.Werner, F.Liu, T.Pierog, hep-ph/0506232

On the example of Drell-Yan or di-jets (effective rapidity shift)

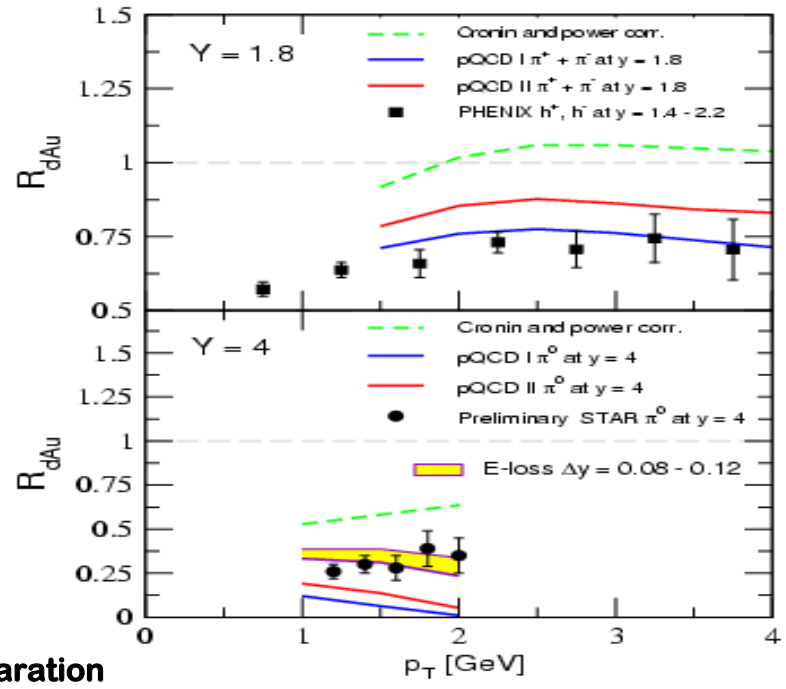

$$\Delta y(\text{mid rap.}) = 0.25 - 0.35 \quad \Delta y(\text{forward}) = 0.08 - 0.12$$

Forward Observables

Rapidity asymmetry

Forward Y suppression

- Reduces the centrality dependence of the Cronin effect around $Y=0$
- Generates rapidity asymmetry (from backward enhancement to forward suppression)
- Consistent with suppression at smaller C.M. energies (NA35 at 17 GeV)
- Indicative of Y and p_T dependence of the cold nuclear matter quenching – to be studied in detail for **LHC applications**

T.Goldman, M.Johnson, J.Qiu, I.V. in preparation (similar results for heavy quarks)

Conclusions

- ▶ **Energy loss formulations** to all orders on the mean number of scatterings exist. Should be formulated in terms of transparent physical quantities. Correctly incorporated in the pQCD calculations.
- ▶ Inclusive particle quenching is the first handle on the densities achieved in heavy ion collisions. At RHIC extracted $e = 15 \text{ GeV/fm}^3$ At the LHC anticipated $e > 200 \text{ GeV/fm}^3$
- ▶ Redistribution of the energy. For tagged to $p_T=4 \text{ GeV}$ at RHIC and **much higher** at the LHC. In terms of **angular** re-distribution of the energy - large and measurable according to the calculated distributions.
- ▶ "Heavy quarks" **don't** seem to be consistent with **normal densities**. Are these heavy quarks? Is this the correct e-loss mechanism?
- ▶ **Forward rapidity** particle production is indicative of power corrections and energy loss. Cold nuclear matter energy loss **should be studied** great detail for applications at the LHC.
