Information Society

- **The APT-Kickstart server is useful when you have a large number of computers to install.**
- **It install a node via kickstart using the PXE technology and manage a local APT repository for OS and middleware**
- **The services to configure are a DHCP server, a TFTP server and a HTTP server**

The main server components required are:

- A **DHCP** server to provide network information about the nodes that will be installed;
- A **TFTP** server to provide the required files during the first phase of OS installation process;
- The **pxelinux** bootloader to select the installation type via PXE;
- Two files containing the initial **kernel** and **ramdisk image**;
- A **kickstart file** describing all the parameters needed to perform the OS installation;
- A **web server** containing the local repository of the operating system and all software needed.

- Run the **GILDA\_APT** virtual machine on your PC
- Set ip address and hostname on your machine following this schema:
  - **apt-kick151d.healthgrid.org --> 192.168.0.171**
  - .....
  - .....
  - **apt-kick161d.healthgrid.org --> 192.168.0.181**
- **reboot**

- [http://grid-it.cnaf.infn.it/apt/ig\\_sl3-i386/RPMS.utils/](http://grid-it.cnaf.infn.it/apt/ig_sl3-i386/RPMS.utils/)
- install the latest version of **ig-installserver** and **ig-yam**
- create these directories:
  - `cd /tftpboot/`
  - `mkdir slc306-i386`
  - `cd /var/rep`
  - `mkdir -p slc306-i386/localrpms/`
- download java and put it under **slc306-i386/localrpms**

**ig-installserver** provides:

- **/etc/dhcpd.conf.example** : ISC dhcpd 3.0 configuration example;
- **/tftpboot/pxelinux.cfg/\*.cfg** : pxelinux configuration files;
- **/usr/sbin/ig-bootselect** : interactive tool to select the boot type;
- **/var/www/cgi-bin/install\_ack.cgi** : CGI script to receive ack for end of installation;
- **/var/www/cgi-bin/set\_static\_ip.cgi** : CGI script to provide kickstart files with static IP configuration;
- **/var/www/html/install/ks/\*.ks** : kickstart file examples.
- **/var/www/html/install/ks/node-generic-slc304-static.ks** : kickstart file example for node with one network interface;

**/etc/dhcpd.conf** example:

```
option domain-name "YOUR_DOMAIN";
option domain-name-servers YOUR_DNS_SERVERS;
not authoritative;
ddns-update-style none;
ignore unknown-clients;
allow bootp;
allow booting;
subnet YOUR_SUBNET netmask YOUR_NETMASK {
  filename "pxelinux.0";
  option routers YOUR_GATEWAY;
  option ntp-servers YOUR_NTP_SERVERS;
  host training150d {
    hardware ethernet 00:30:48:1A:00:00;
    fixed-address 192.168.0.150;
  }
}
```

```
/sbin/chkconfig dhcpd on
```

```
/sbin/service dhcpd restart
```

The client, after the network configuration is provided by DHCP, needs to retrieve the bootable kernel and ramdisk Image. These files are uploaded using the TFTP protocol.

**`/etc/xinetd.d/tftp`**

Make sure that the directive "disable" is "no" and verify that the root directory of the tftp server is **`/tftpboot`**. This directory is very important since it contains the files transferred to the client during the PXE boot process. Once the tftp daemon is configured it can be accessed via xinetd with:

**`/sbin/chkconfig xinetd on`**

**`/sbin/service xinetd restart`**

The bootloader used by the PXE installation is pxelinux.0; it is provided by the syslinux package:

**syslinux-<version>.rpm**

Copy the loader pxelinux.0 in **/tftpboot**:

```
cp /usr/lib/syslinux/pxelinux.0 /tftpboot/  
chmod 644 /tftpboot/pxelinux.0
```

The kernel and the initrd have to be available via TFTP to start the installation via network. Create the directory for kernel and initrd and download them from the OS distribution mirror:

```
cd /tftpboot/slc306-i386 (created by ig-installserver)
wget http://linuxsoft.cern.ch/cern/slc306/i386/images/pxeboot/initrd.img
wget http://linuxsoft.cern.ch/cern/slc306/i386/images/pxeboot/vmlinuz
chmod 644 vmlinuz initrd.img
```

```
cd /var/www/html/rep/slc306-i386/base
wget -l1 -nd -c -r -R '*.html,*.gif' \
http://linuxsoft.cern.ch/cern/slc306/i386/SL/base/
```

```
cd /var/www/html/install
ln -s /var/www/html/rep/slc306-i386/ SL
```

This is required by the OS installer (Anaconda), it needs to find the base directory inside the **SL**

It will be used to:

- distribute OS and middleware packages via APT
- kickstart files
- provide the kickstart file adapted with the information about static IP address that has to be set on the currently installed machine
- receive the notification of the installation finished, necessary to automatically set the right pxelinux configuration file and avoid an OS reinstallation

**/sbin/chkconfig httpd on**

**/sbin/service httpd restart**

The package **ig-yam** provides a slightly customized version of **YAM** (<http://dag.wieers.com/packages/yam>). **YAM** is a tool which allows to maintain a local mirror of one or more apt rpm repositories.

**YAM** configuration is managed by **/etc/yam.conf**. It contains a "main" section, in which the path to the local archive, together with the web server root, and one or more "repository" sections for each mirrored object.

```
[main]
srcdir      = /var/rep
wwkdir     = /var/www/html/rep
createrepo = no
apt        = yes
yum        = no

[slc306]
name       = Scientific Linux CERN 3.0.6 (i386)
arch      = i386
os        = http://192.168.0.50/slc306-i386/RPMS.os/
updates   = http://192.168.0.50/slc306-i386/RPMS.updates/
extras    = http://192.168.0.50/slc306-i386/RPMS.extras/
```

```

[glite_sl3]
name           = gLite middleware (i386)
arch           = i386
security       = http://192.168.0.50/glite_sl3-i386/RPMS.security/
3_0_0         = http://192.168.0.50/glite_sl3-i386/RPMS.3_0_0/
3_0_0_externals = http://192.168.0.50/glite_sl3-i386/RPMS.3_0_0_externals/
3_0_0_updates  = http://192.168.0.50/glite_sl3-i386/RPMS.3_0_0_updates/

[ig_sl3]
name           = INFN-GRID middleware (i386)
arch           = i386
utils          = http://192.168.0.50/ig_sl3-i386/RPMS.utils/
3_0_0         = http://192.168.0.50/ig_sl3-i386/RPMS.3_0_0/

[gilda_app]
name           = GILDA Applications Software (i386)
arch           = i386
3_0_0         = http://192.168.0.50/gilda_app-i386/RPMS.3_0_0/

# Copy here your additional packages
localrpms     = file:///var/rep/slc306-i386/localrpms/
    
```

You have to use three basic commands to synchronize the repository:

**yam -uvv** : to synchronize the os and updates modules;

**yam -xvv** : to synchronize modules different from os and updates (e.g. extras);

**yam -gvv** : to create the package lists (using the command "genbasedir" of the apt tool) and to create all the symbolic links in the webserver directory.

**yam -guxvv**: performs all the steps in one shot

**yam -guxvv -d 'repository section-arch'**: performs all the steps for the given repository.

Ex. **yam -guxvv -d 'gilda\_app-i386'**

The kickstart file contains all the information about the packages to be installed, the partitions to be prepared on the disks, the hardware settings, the network settings, etc..

An example is installed by `ig-installserver` under `/var/www/html/install/ks/`

You can set two possible network configurations:

- **Dynamic:** `network -device eth0 -bootproto dhcp`
- **Static:** `network -device eth0 -bootproto static -ip \`  
`<auto_retrieved_ip> -netmask <your_netmask> -gateway \`  
`<your_gateway> -nameserver <your_dns1>,<your_dns2>`
- In the **%partition** section the disks are prepared.
- The **%package** section contains information about the software to be installed.
- In the **%post** section some additional custom commands can be specified.

- pxelinux.0 will be executed and it will try to download a configuration file.
- An example of configuration file (</tftpboot/pxelinux.cfg/node-embrace-slc306.cfg>):

```
default linux
```

```
label linux
```

```
kernel slc306-i386/vmlinuz
```

```
append \
```

```
ksdevice=eth0 ip=dhcp initrd=slc306-i386/initrd.img \
```

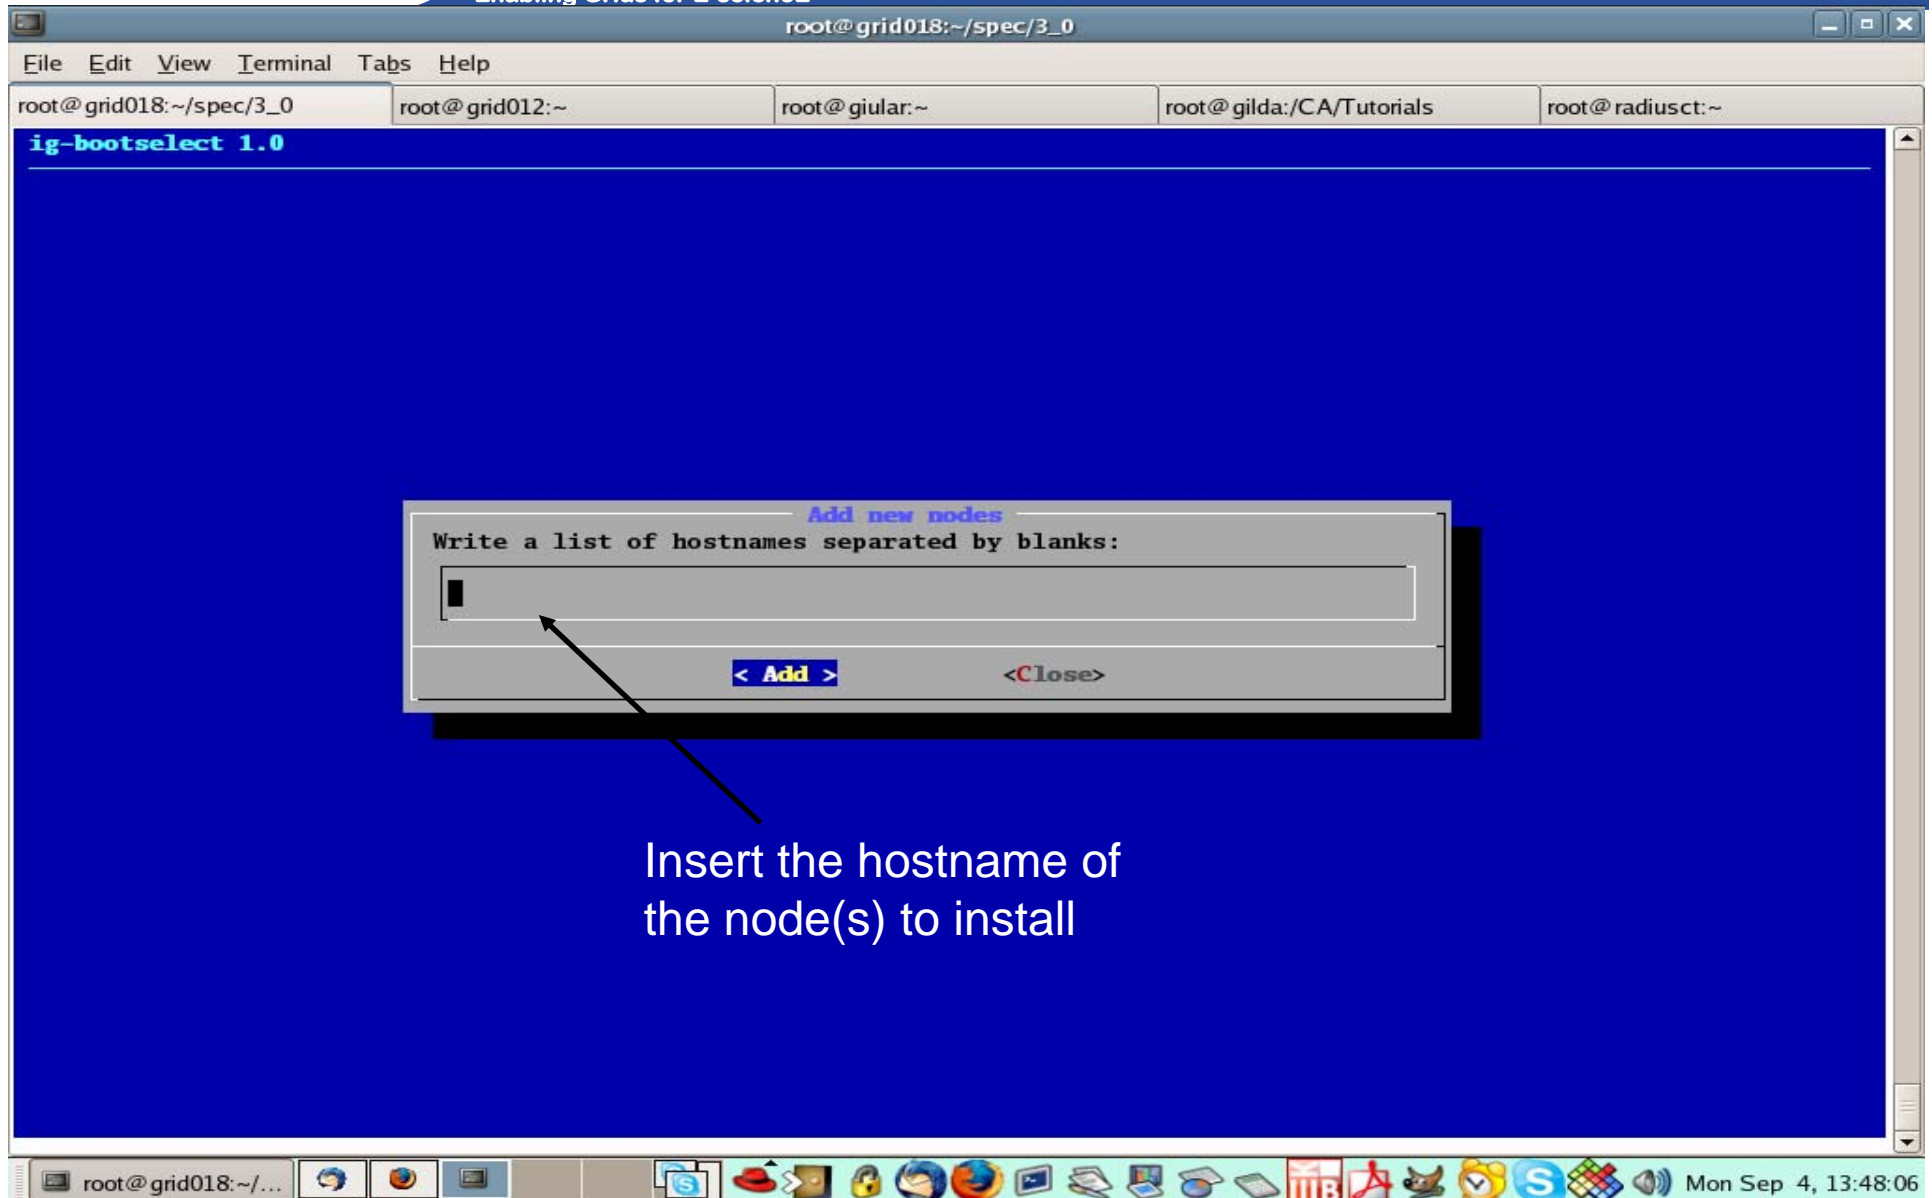

```
ks=http://<server>/install/ks/node-embrace-slc306.ks
```

- **/etc/dhcpd.conf**: configuration file of DHCP server;
- **/etc/xinetd.d/tftp**: configuration file of TFTP server;
- **/tftpboot/pxelinux.0**: PXE bootloader;
- **/tftpboot/slc304-i386/vmlinuz**: kernel loaded during OS installation;
- **/tftpboot/slc304-i386/initrd.img**: initial ramdisk loaded during OS installation;
- **/tftpboot/pxelinux.cfg/node-generic-slc304-static.cfg**: bootloader configuration files;
- **/tftpboot/pxelinux.cfg/XXXXXXXXXX**: symlinks to a bootloader configuration files (see final step);
- **/var/www/html/install/ks/node-generic-slc304-static.ks**: kickstart file;

- Ensure in the BIOS that the boot sequence starts with the network card (PXE);
- Verify that it is correctly registered in the **DNS**;
- Verify that its **MAC address** is present in dhcpd.conf; if necessary restart the **DHCP** server to reload the new configuration (if you choose static network configuration this is needed only for installation);
- Check the customizations in **node-embrace-slc306-.cfg**: in this file you choose which kickstart file will be used
- Please note that if you rename or create a new copy of the kickstart file, the new name has to be written in a corresponding **.cfg pxelinux** configuration file.

You have to run **/usr/sbin/ig-bootselect:**

- to provide one (or more) hostname to add. In case of errors check if your domain is present in `/etc/resolv.conf`;
- to change the pxelinux configuration to use.
- The symlink from the chosen configuration to the IP address in hex format will be created.

root@grid018:~/spec/3\_0

File Edit View Terminal Tabs Help

root@grid018:~/spec/3\_0 root@grid012:~ root@giular:~ root@gilda:/CA/Tutorials root@radiusct:~

**ig-bootselect 1.0**

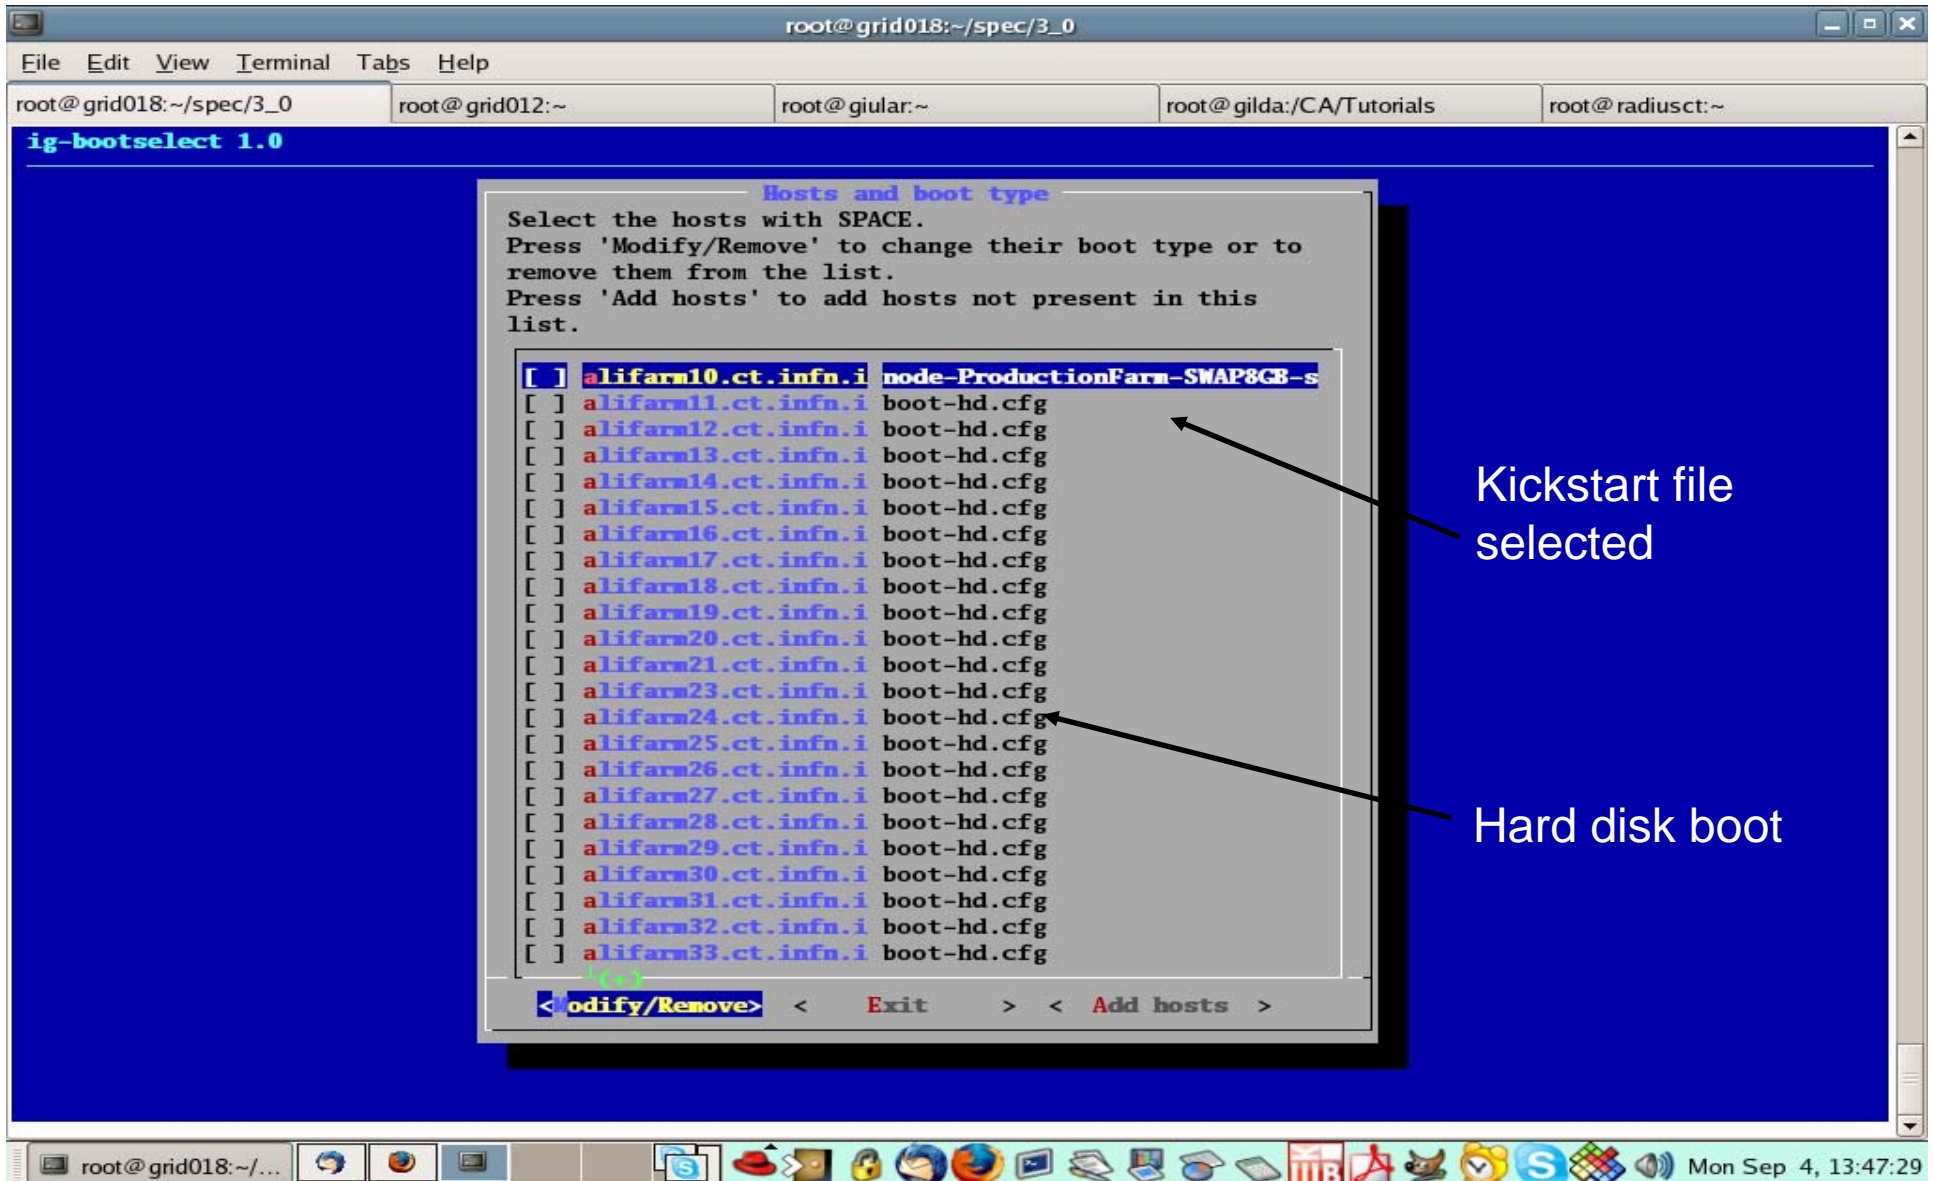

**Add new nodes**

Write a list of hostnames separated by blanks:

**< Add >** **<Close>**

Insert the hostname of the node(s) to install

root@grid018:~/spec/3\_0 root@grid012:~ root@giular:~ root@gilda:/CA/Tutorials root@radiusct:~

**ig-bootselect 1.0**

**Hosts and boot type**

Select the hosts with SPACE.  
Press 'Modify/Remove' to change their boot type or to remove them from the list.  
Press 'Add hosts' to add hosts not present in this list.

Kickstart file selected

Hard disk boot

root@grid018:~/... Mon Sep 4, 13:47:29

- Edit **GILDA\_node.vmx** and put these lines:
  - `ethernet0.addressType = "static"`
  - `ethernet<number>.address = 00:50:56:1A:XX:FF`
- Start **GILDA\_node** virtual machine
- Press F2 to enter the network adapter at the top of the boot order
