Long Range effect 2012

Regular Physics Fill of 2012 RUN LHC

Fill No. 2710 Bunch by bunch luminosity decay rate 0-1 hours LR comparison

Clear Long Range pattern in the Luminosity and Specific luminosity decay rates

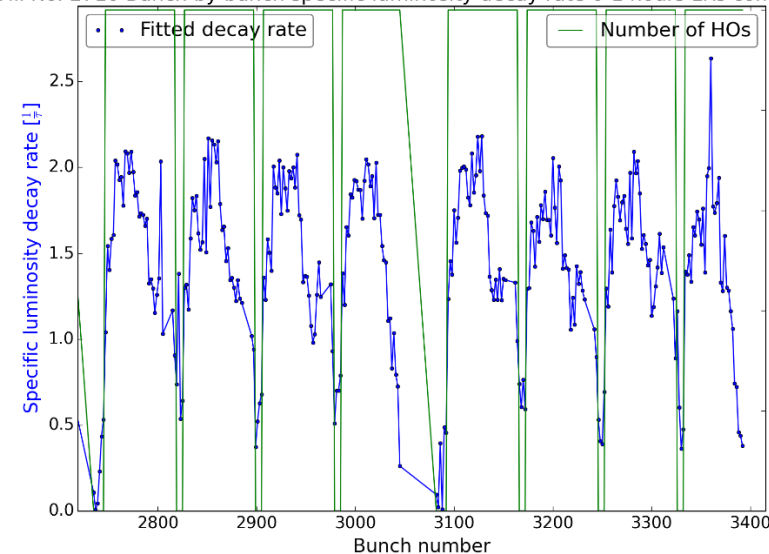

Losses and emittance blow-up has a clear BB pattern

2012 Beam-Beam parameter of 0.0067/IP

- 2 HO 0.015 total
- IP2 and IP8 with relevant long ranges
- Octupoles at maximum current...
- Chromaticity to 20 units....

“see also analysis of F. Antoniou”

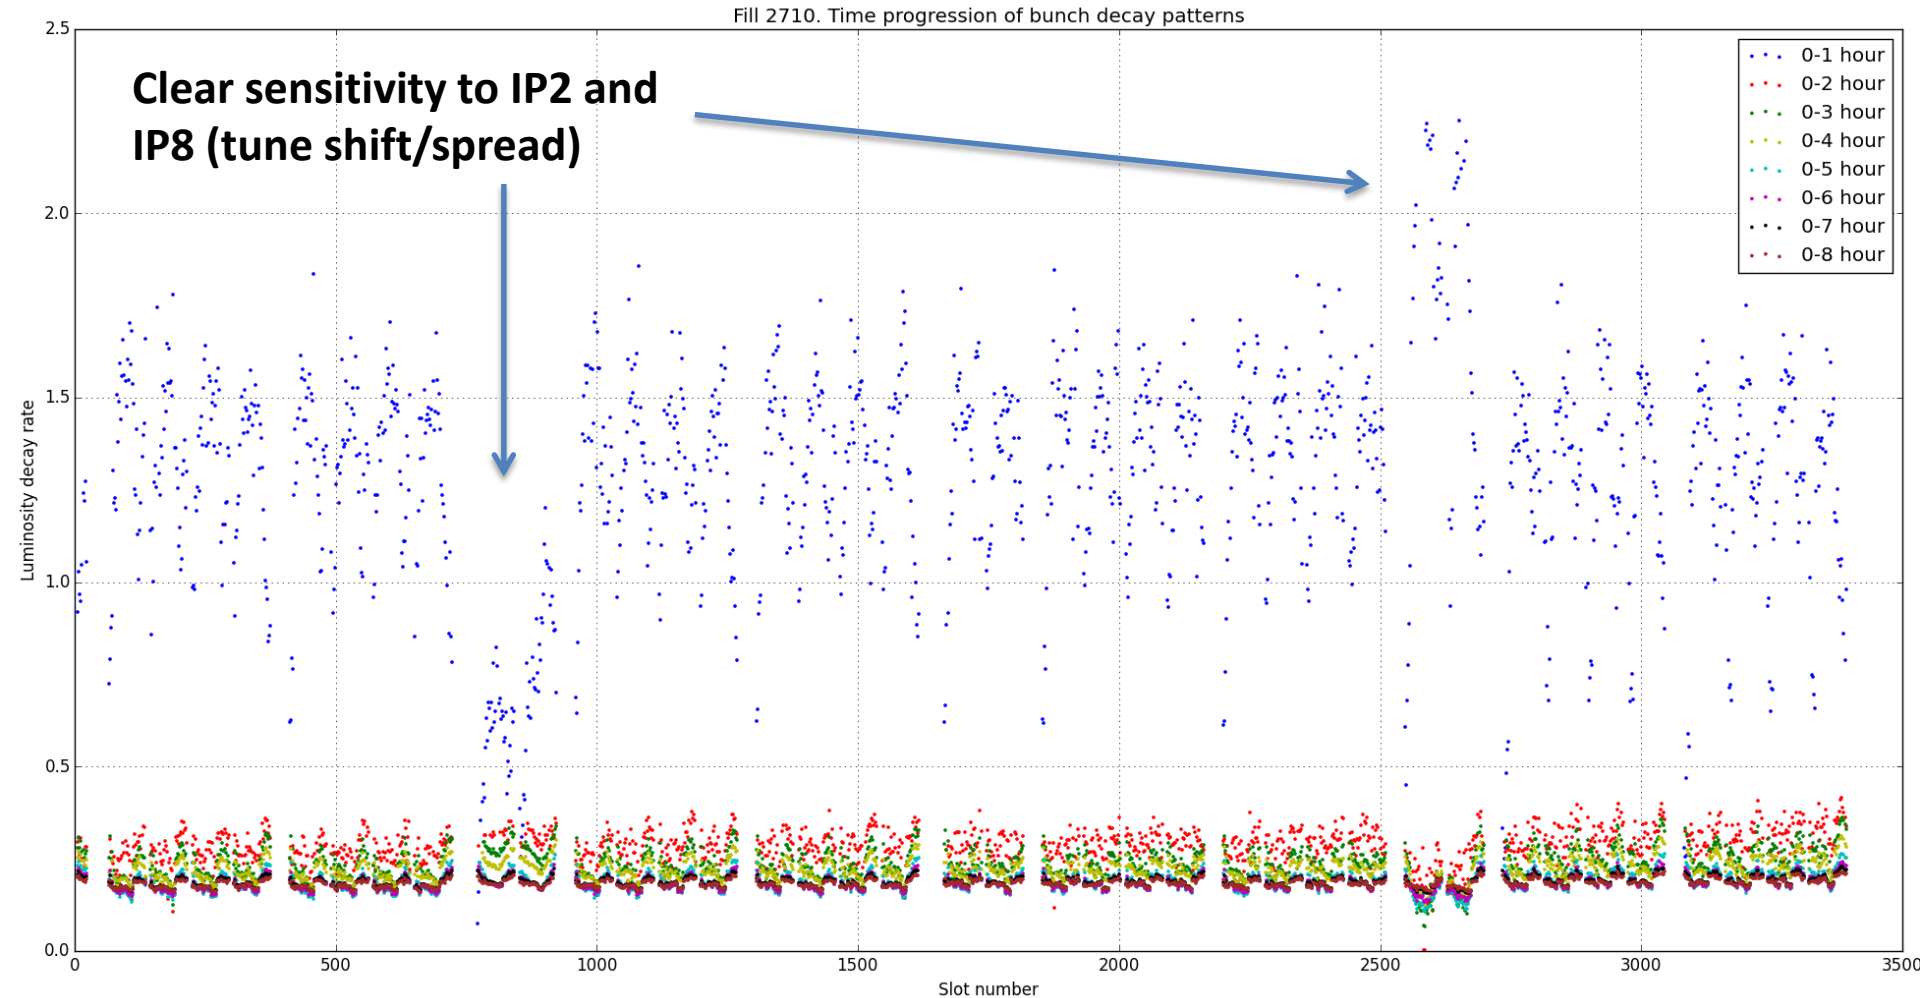

Fill No. 2710 Bunch by bunch specific luminosity decay rate 0-1 hours LR comparison

Long Range effect 2012

Regular Physics Fill of 2012 RUN LHC

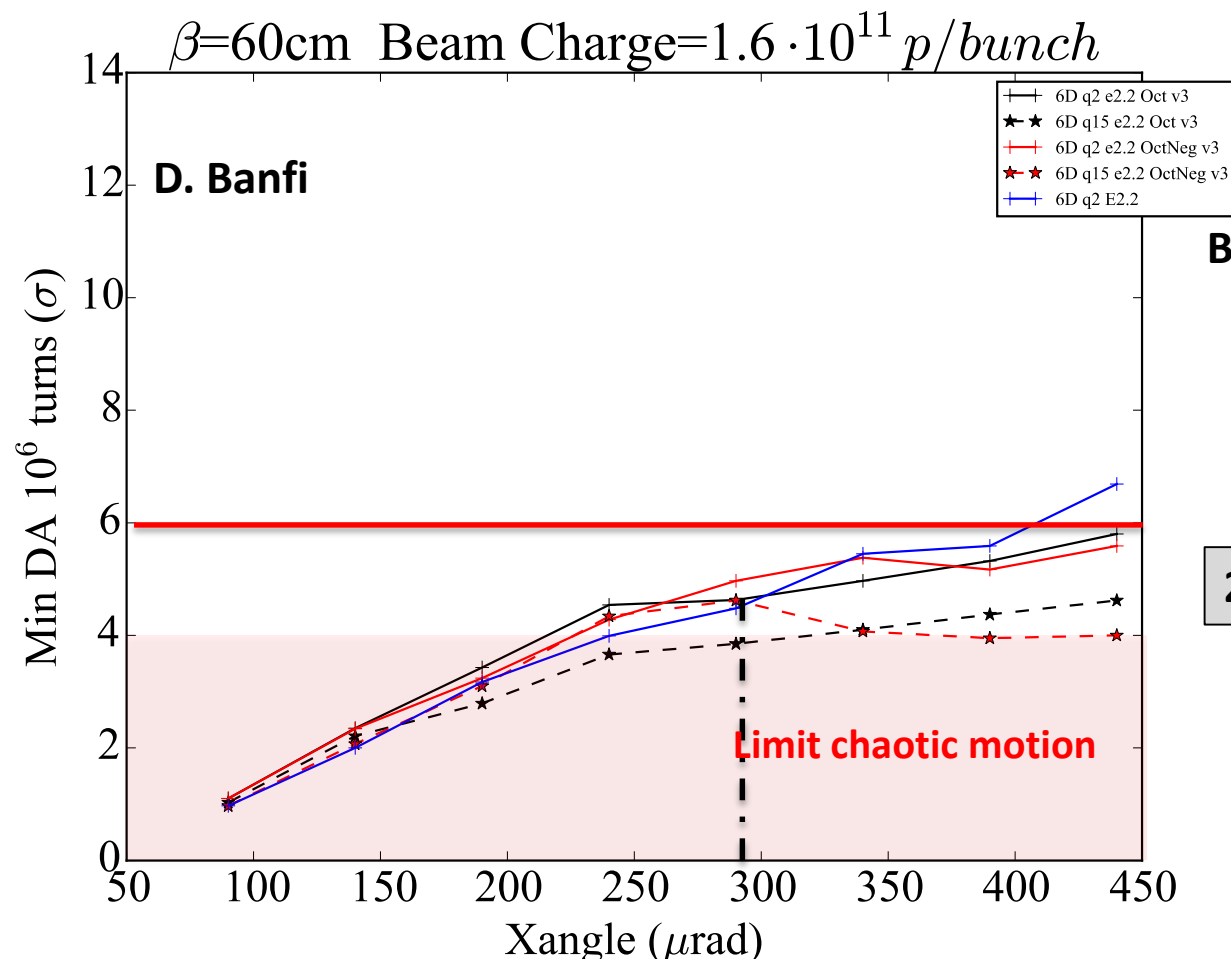

A. Esmail-Yakas

Beam-Beam pattern visible in first 2 Hours of physics fills

Also special IP2 and IP8 effects visible missing head-on collision and/or long ranges

2012 Physics RUN

Beam parameters:

$N_b = 1.6/1.7 \text{ e}11 \text{ ppb}$

$\varepsilon = 2.5\text{-}3.5 \mu\text{m}$

IP8 leveled offset = 2.5σ

$Q' = 15$ units

Oct 550A

Beam-Beam separation at first LR

$$d_{sep} = \alpha \cdot \sqrt{\frac{\gamma \cdot \beta^*}{\epsilon}}$$

2.2 μm beams $\rightarrow d_{sep} = 10 \sigma$

- **High Chromaticity (15-20)** has very **BAD** impact on Dynamic Aperture!
 - **High Octupoles (550 A)** has very **BAD** impact on Dynamic Aperture!
- All needed to fight coherent instabilities in the squeeze...**

2012 Physics RUN

Beam parameters:

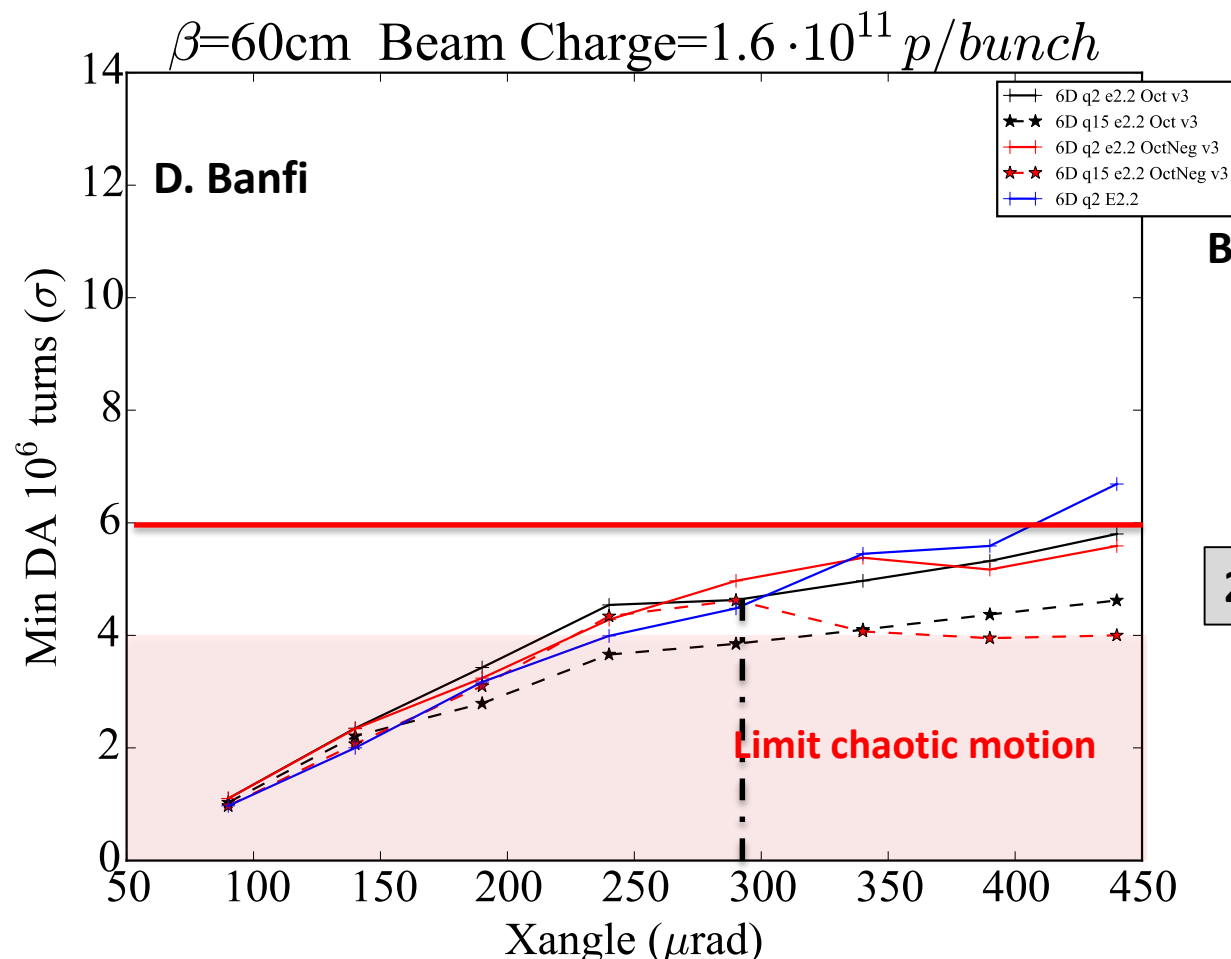

$N_b = 1.6/1.7 \text{ e}11 \text{ ppb}$

$\varepsilon = 2.5\text{-}3.5 \text{ } \mu\text{m}$

IP8 leveled offset = 2.5σ

$Q' = 15 \text{ units}$

Oct 550 A

Beam-Beam separation at first LR

$$d_{sep} = \alpha \cdot \sqrt{\frac{\gamma \cdot \beta^*}{\epsilon}}$$

2.2 μm beams $\rightarrow d_{sep} = 10 \sigma$

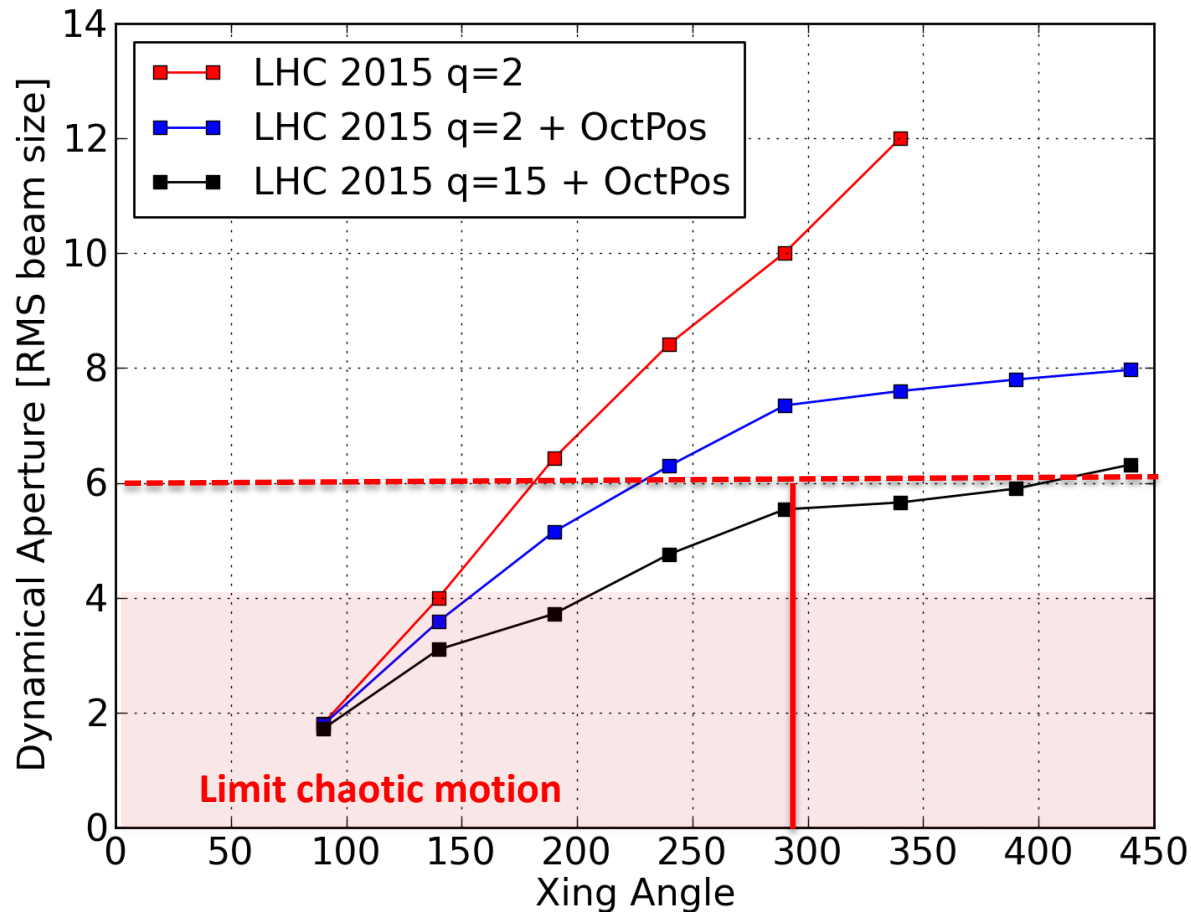

We were at the limit!

Chaotic motion due to beam-beam+ Q' +Oct drives diffusive mechanism (particle losses and emittance blow-up)

Outline

- 2012 Beam Beam effects data and simulations
- **2015 set-up strategy and 2015 Long Range MD**
- 2016 crossing angles
 - IP1&5
 - IP2 with possibility to swap spectrometer
 - IP8 as in 2015
- Stable beams
 - Weak-strong BB Head-on
 - Separation scans and stability of beams
- MDs highlights
 - Beam Transfer Functions
 - Noise on colliding beams
 - Beta-beating
- Summary

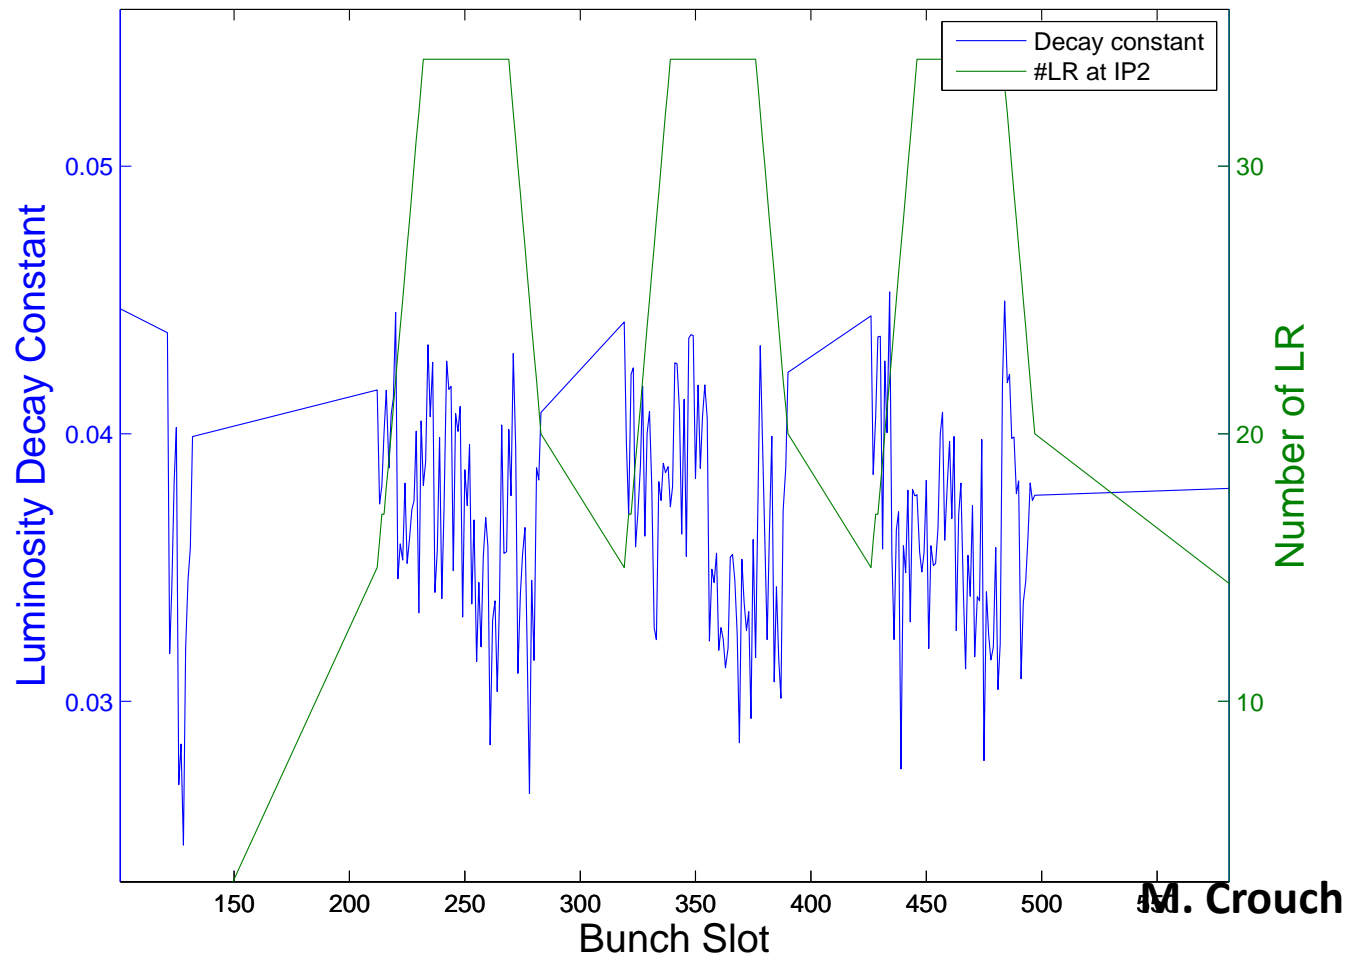

2015 Strategy

- Beam-Beam parameter 0.0037/IP (half of what we had in 2012)
- Long Range weaker to allow high Octupoles and high Chromaticity operation
- 11σ beam-beam separation ($3.75\text{ }\mu\text{m}$ emittances and $1.3\text{ e}11\text{ppb}$)
- Tight control on tune shifts from Beam-Beam Long Range of IP2&8
- 1 Angle for high-low brightness beams (DA depends on Head-on as well)

Long Range beam-beam effects 2015

Regular LHC Physics Fill of 2015

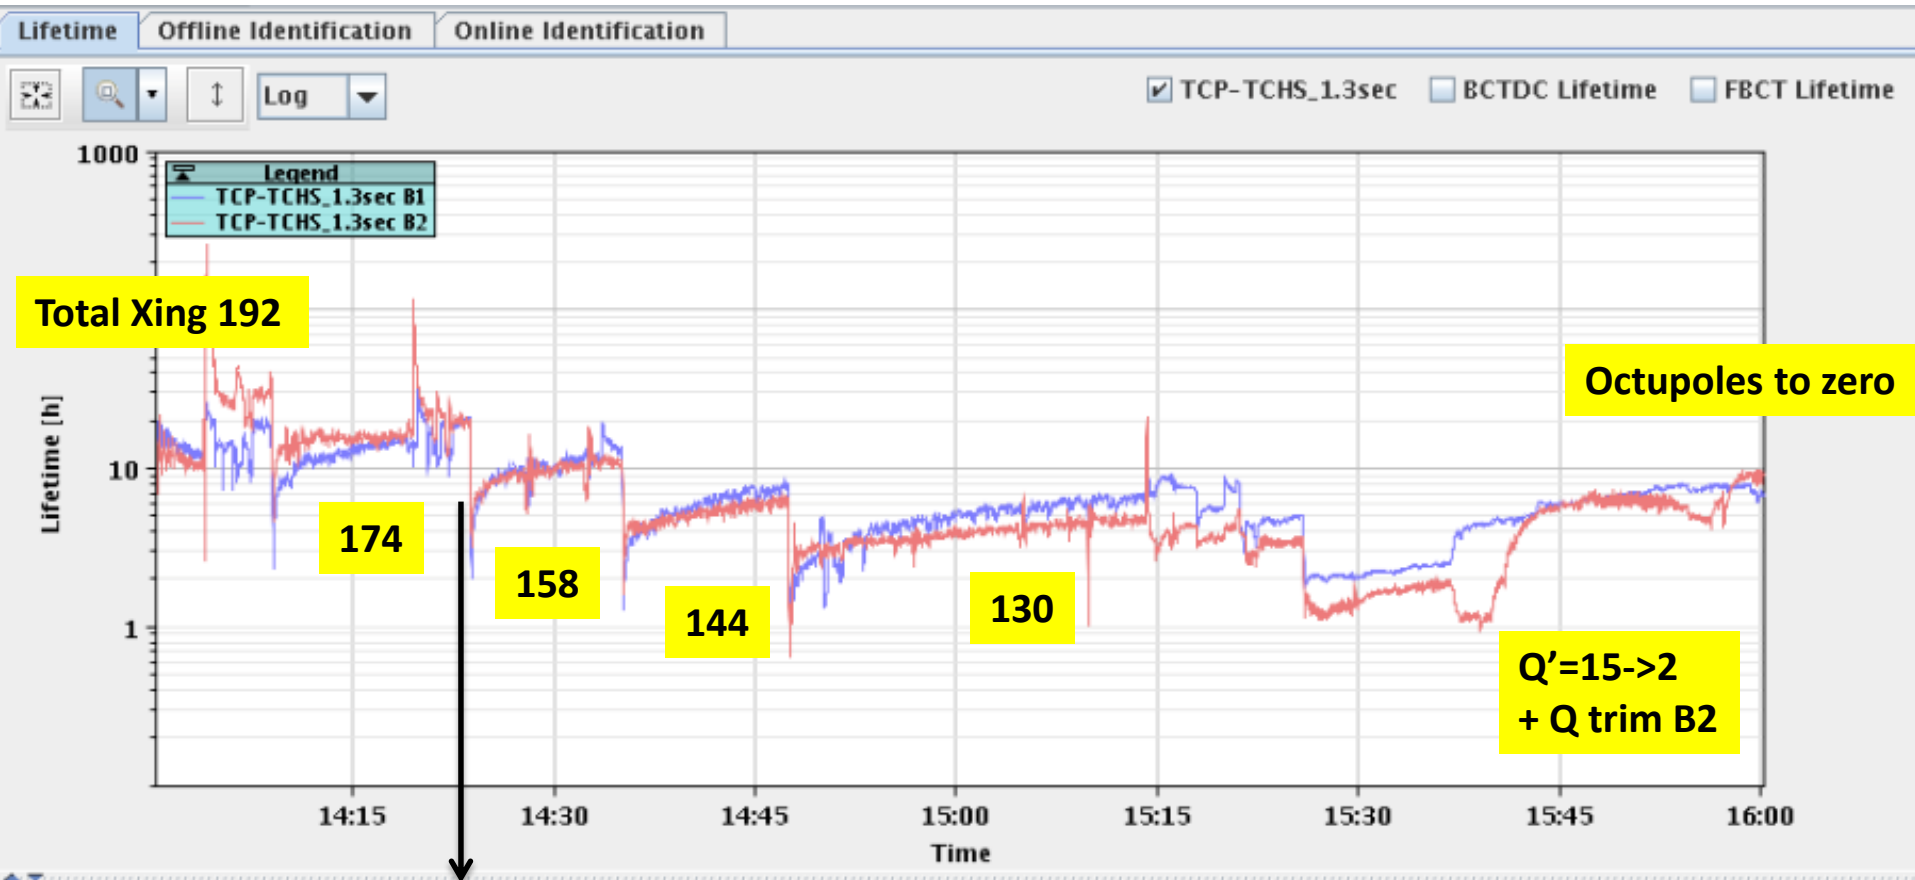

No clear evidence of beam-beam long range and Head-on signature in physics fills

Beautiful Beams and Lumi lifetimes (above 20 hours)!

Long Range Beam-Beam MD 15 September

Quantifying the impact of reduced crossing angle on beam parameters

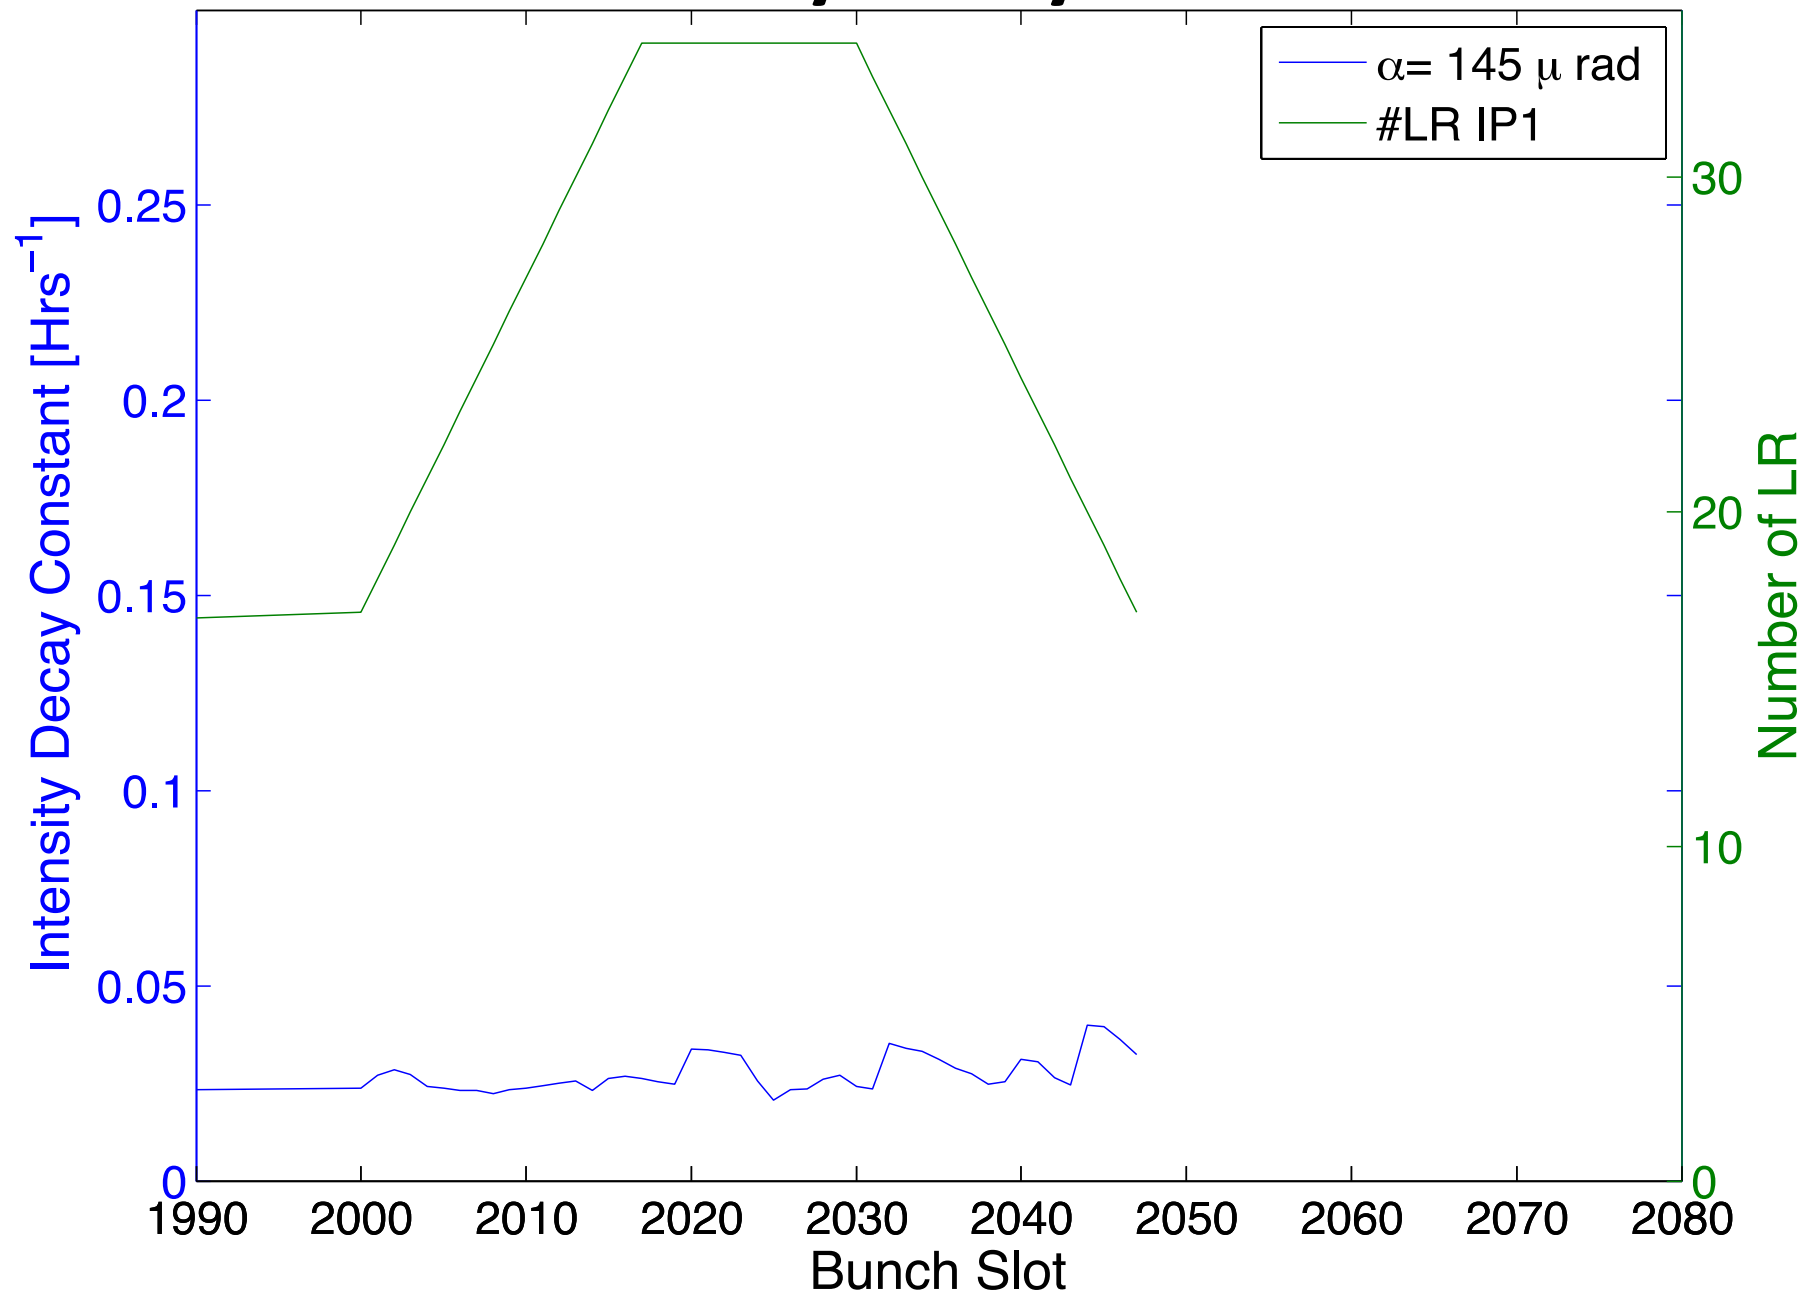

Beam emittances $2.4 \mu\text{m}$, intensities $1.1\text{e}11\text{ppb}$ 48 bunches train

Reduce crossing angle in steps from Total angle $290 \rightarrow 130 \mu\text{rad}$ and quantify impact on beam intensity, emittances and luminosity lifetimes

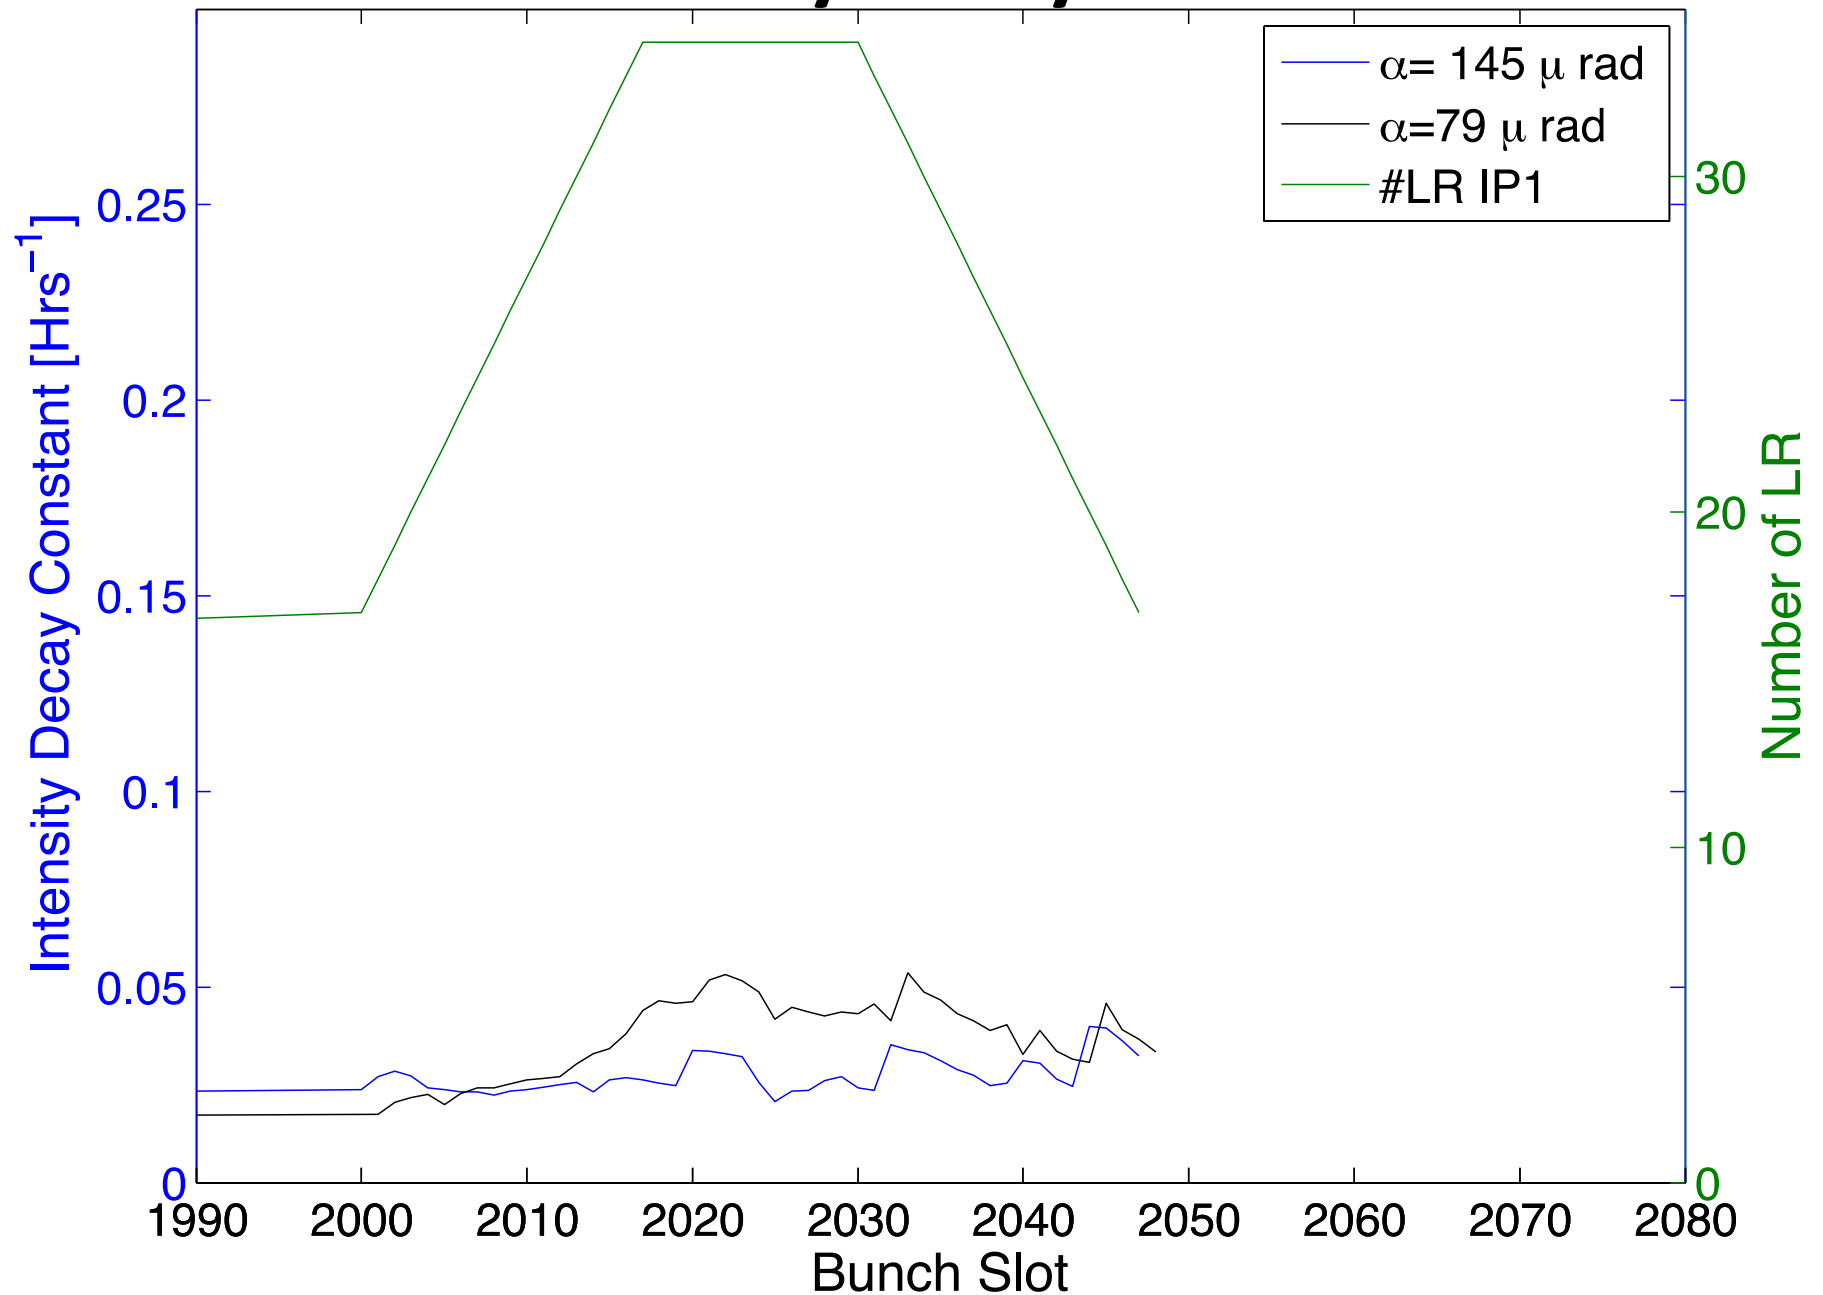

Reduce Q' and Octupoles

Large orbit drifts during large part of MD \rightarrow losing collisions

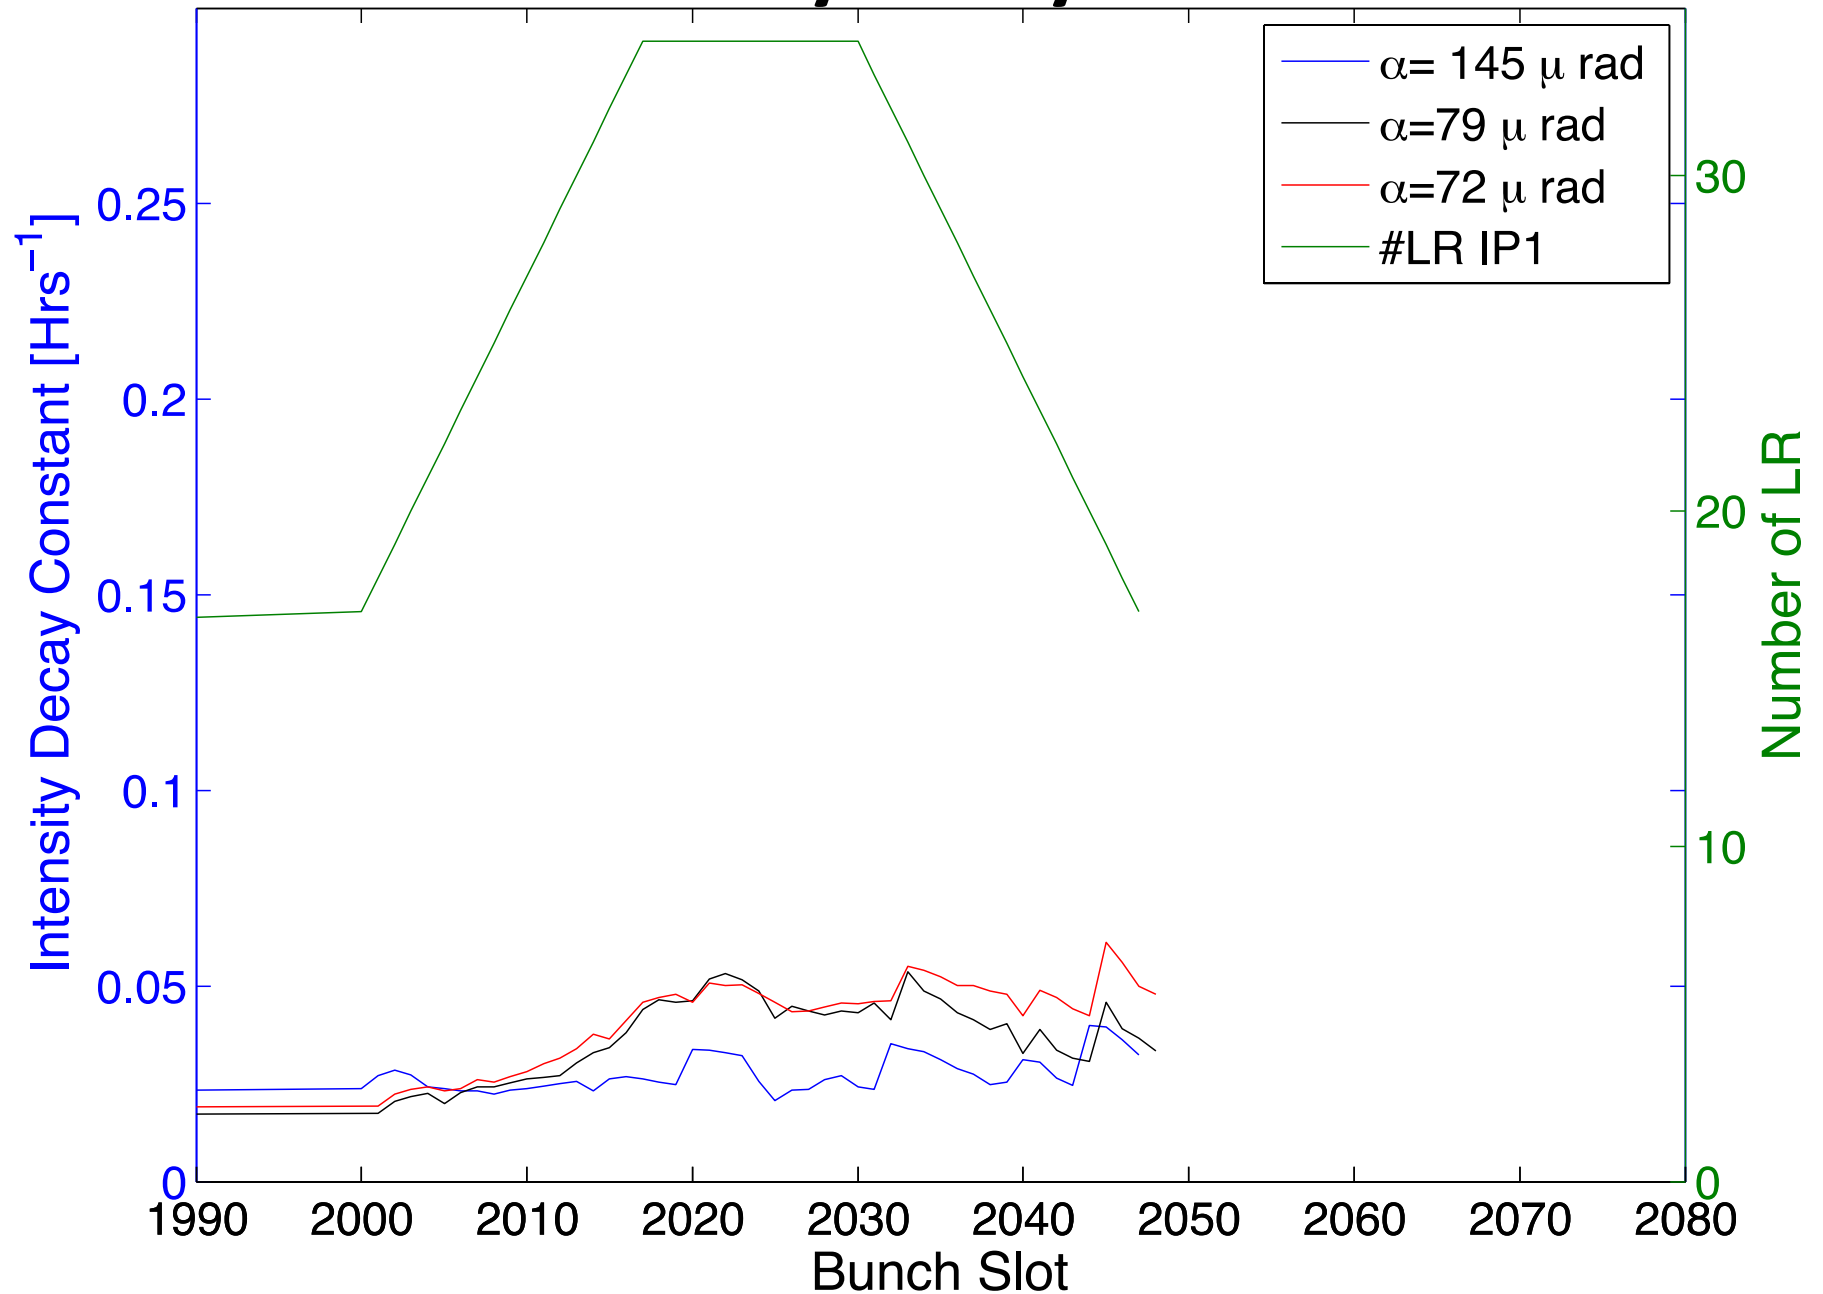

Beam 1 Intensity decay versus bunch

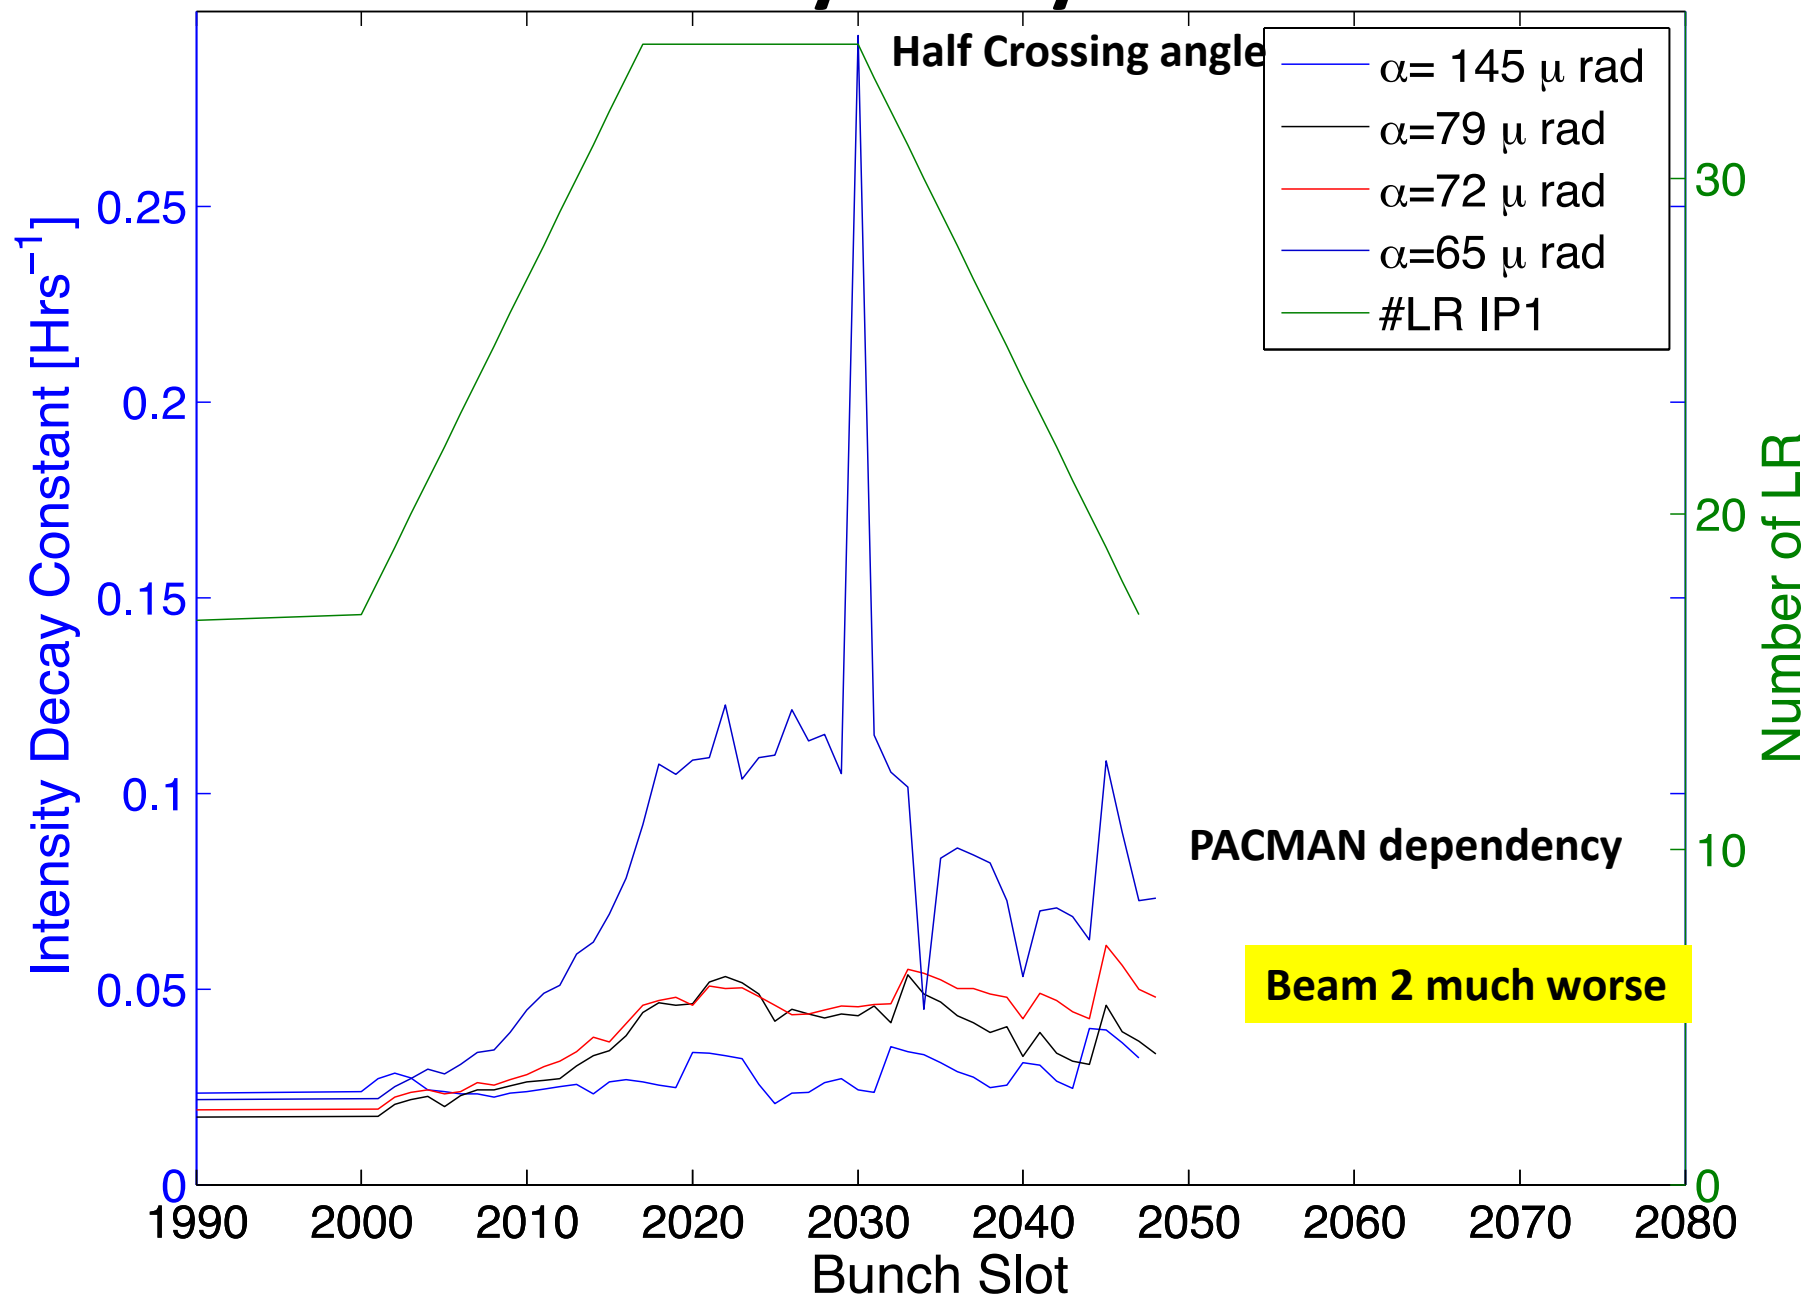

Beam 1 Intensity decay versus bunch

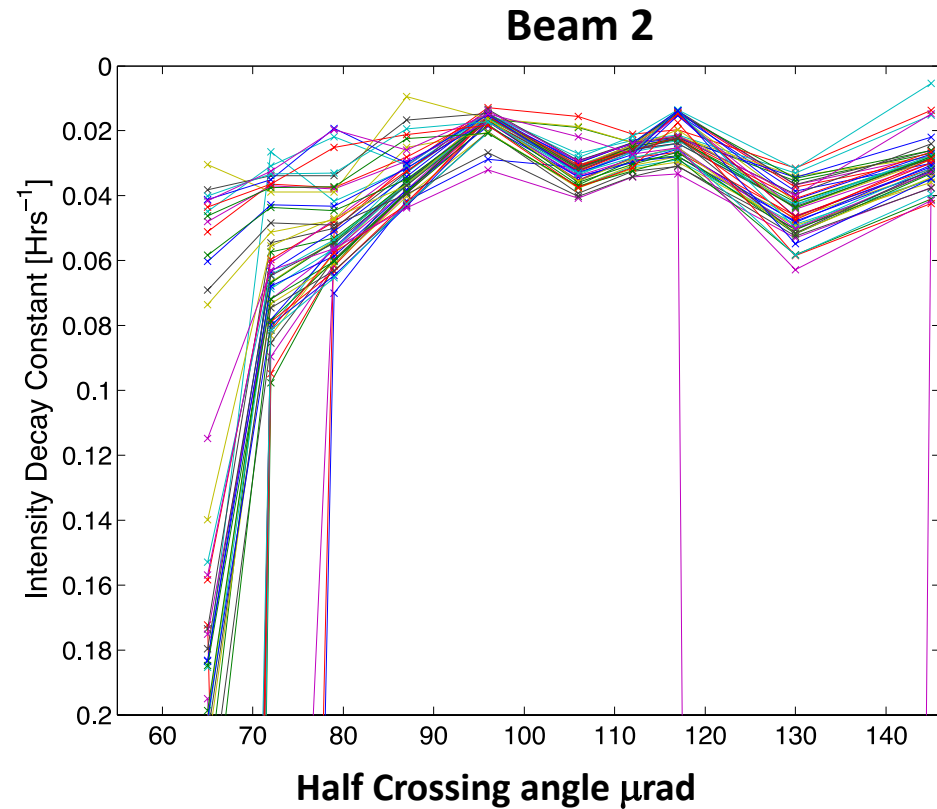

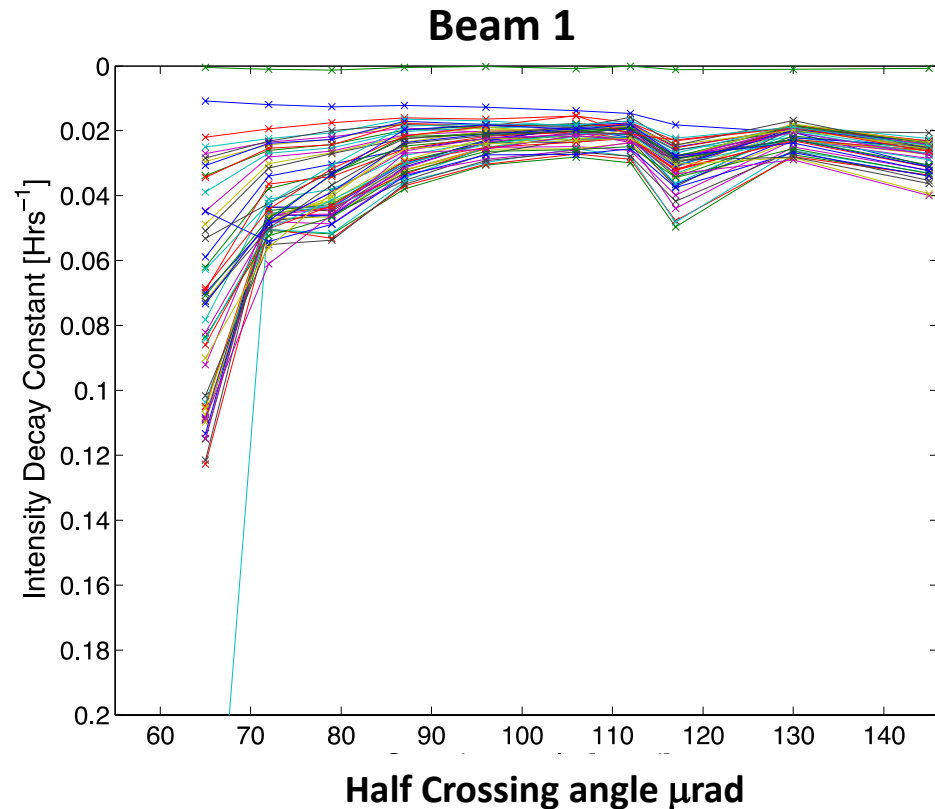

Beam 1 Intensity decay versus bunch

Beam 1 Intensity decay versus bunch

Intensity lifetimes versus crossing angle

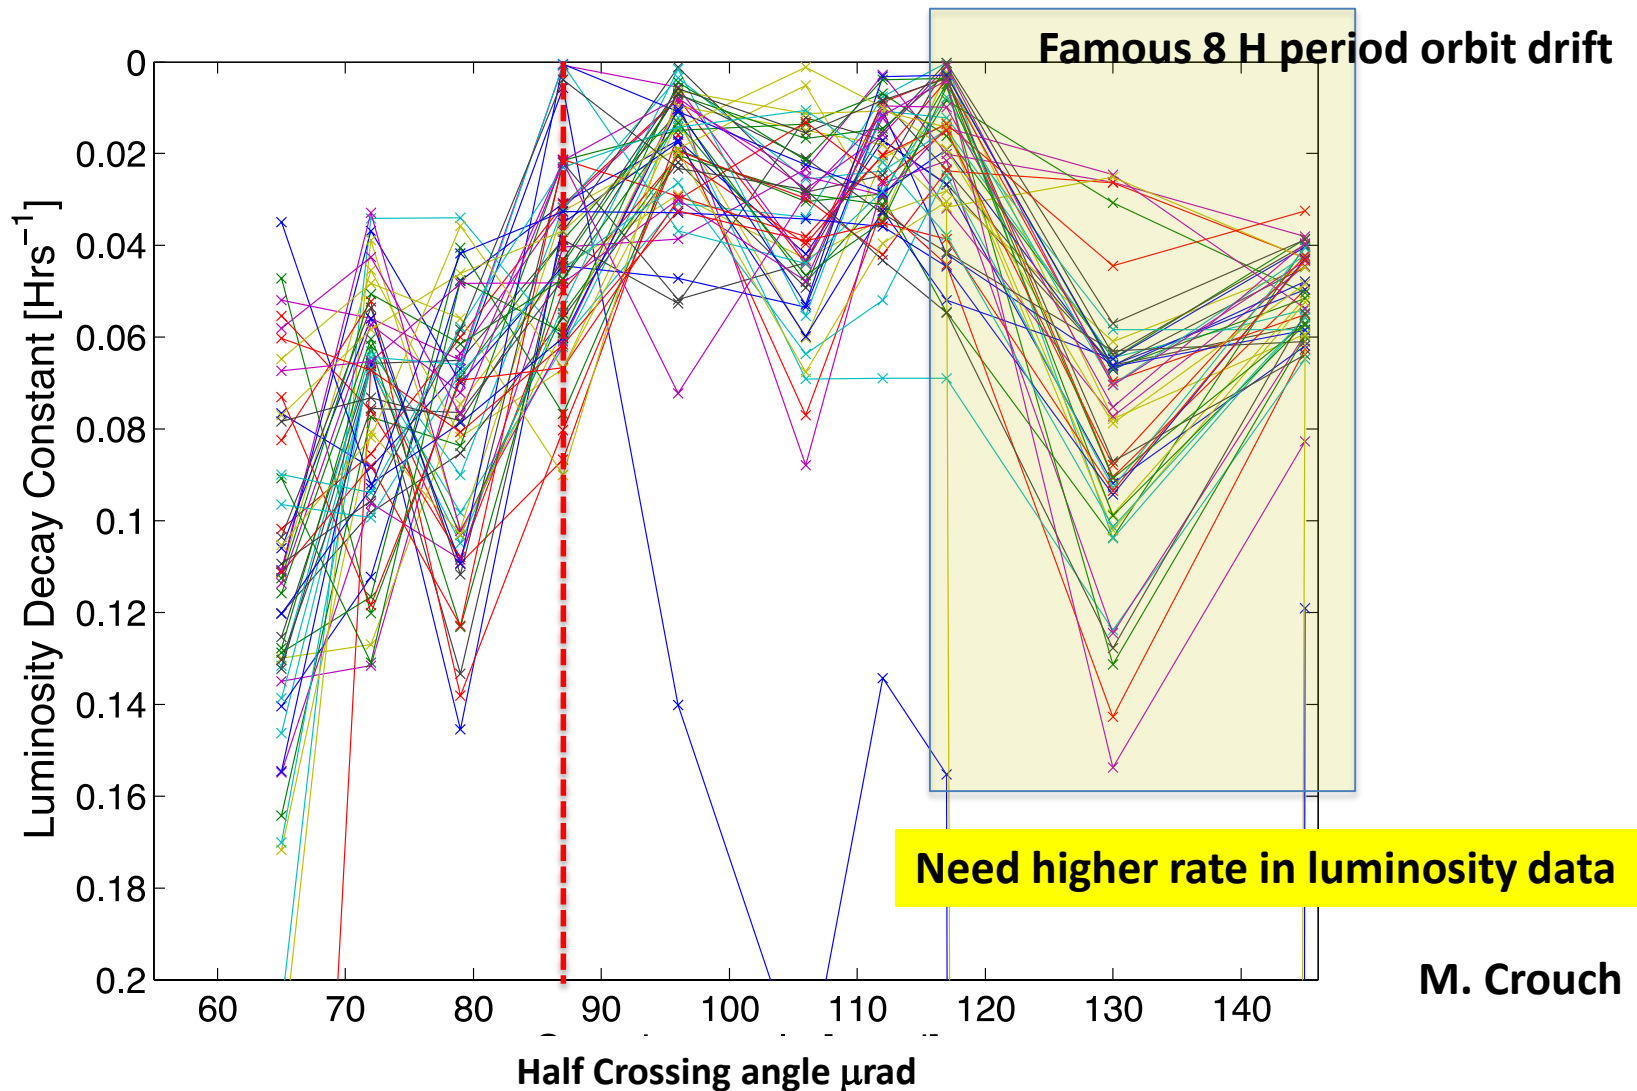

M. Crouch

Reducing the crossing angle Beam lifetimes are reduced from 30→8-5 hours
Beam 2 more sensitive (could be slightly different tune? Different emittances?)

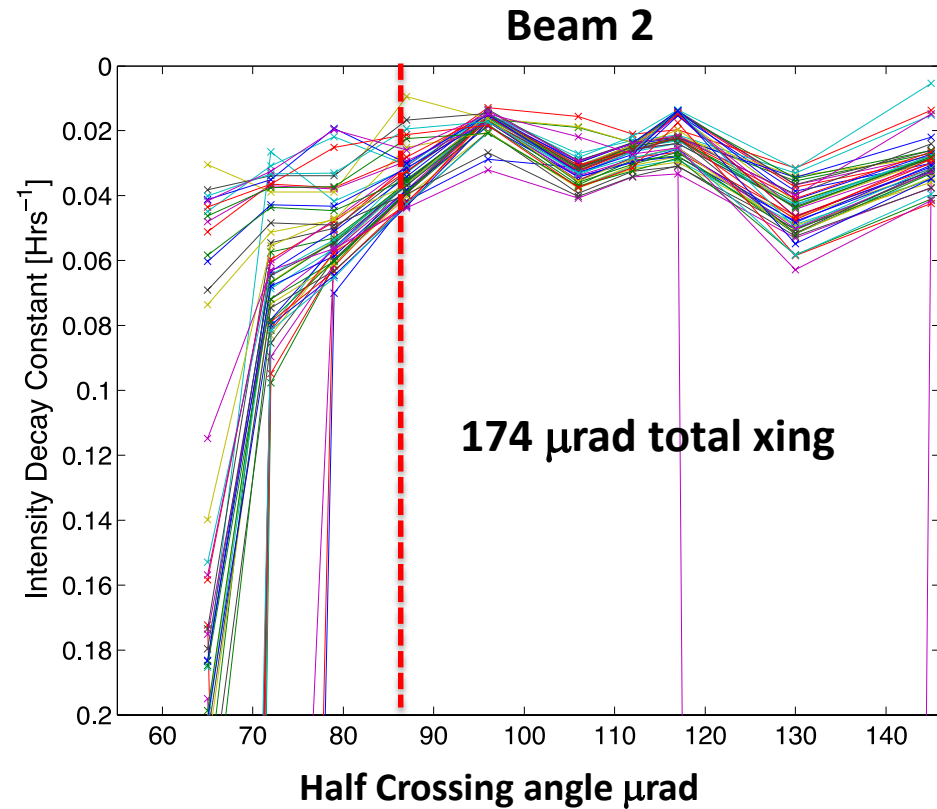

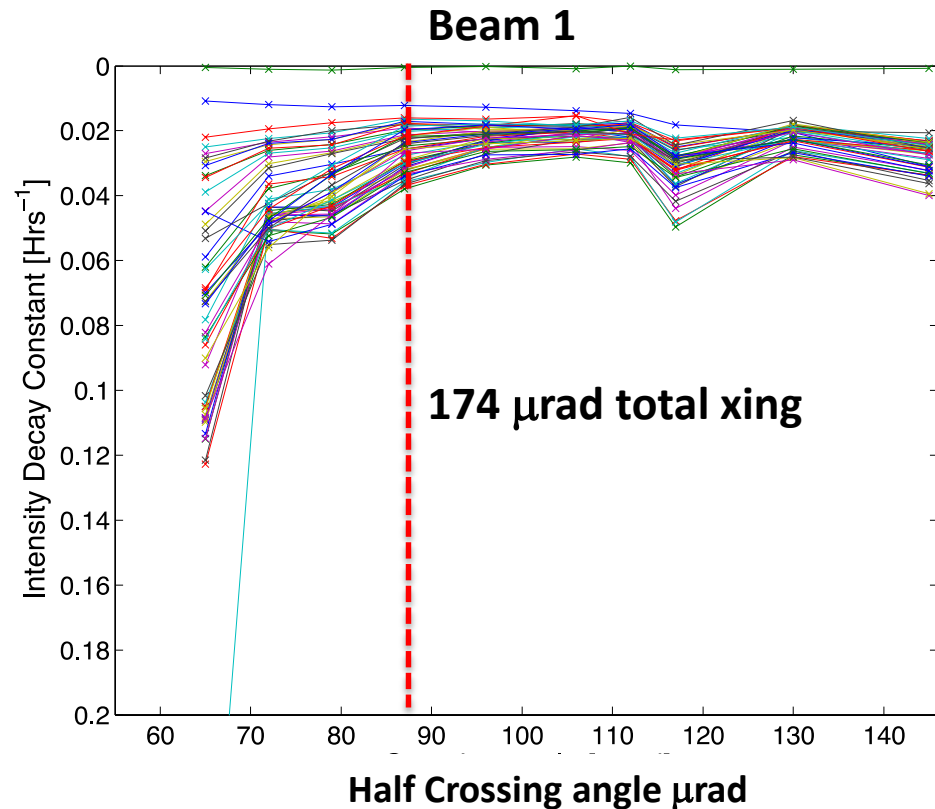

ATLAS Data

Luminosity Lifetime

Reducing the crossing angle Luminosity lifetime reduces from 30 → 12 → 5 hours

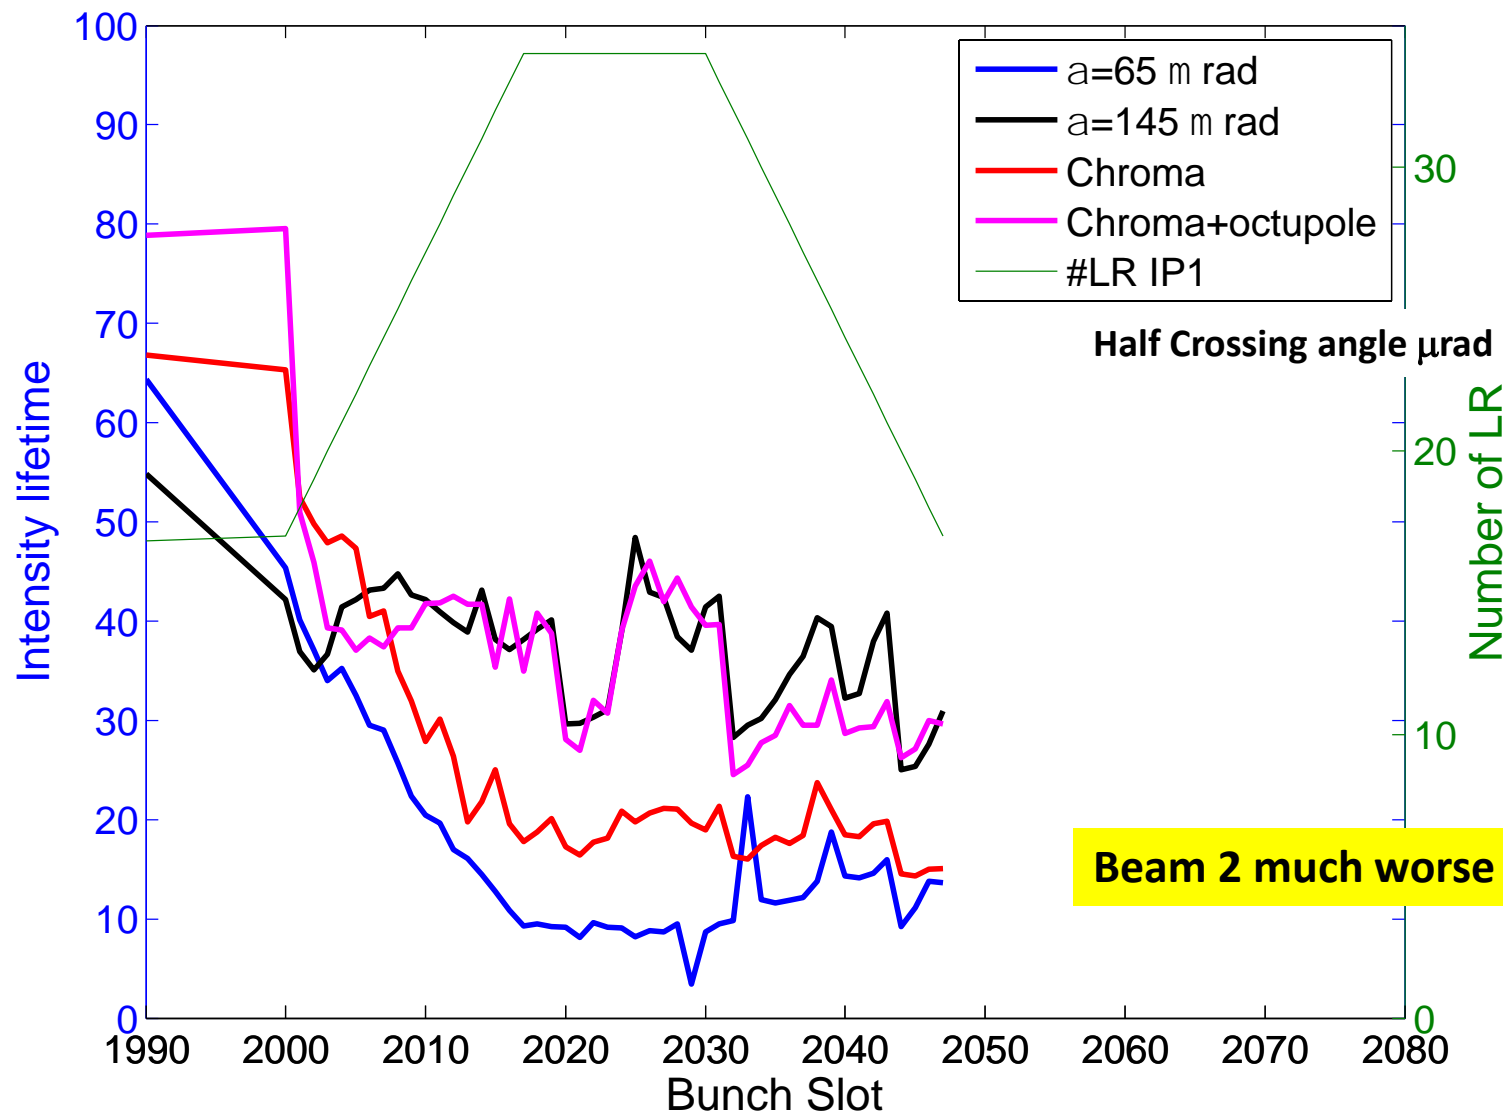

Intensity lifetimes versus xing angle

M. Crouch

For angles below this limit Beam lifetimes go below 20 hours Lumi lifetime at 12 hours
Onset of losses with Long Range patterns occurs at a beam-beam separation of 8.5σ

Beam 1 Intensity lifetimes versus Q' and Octupoles

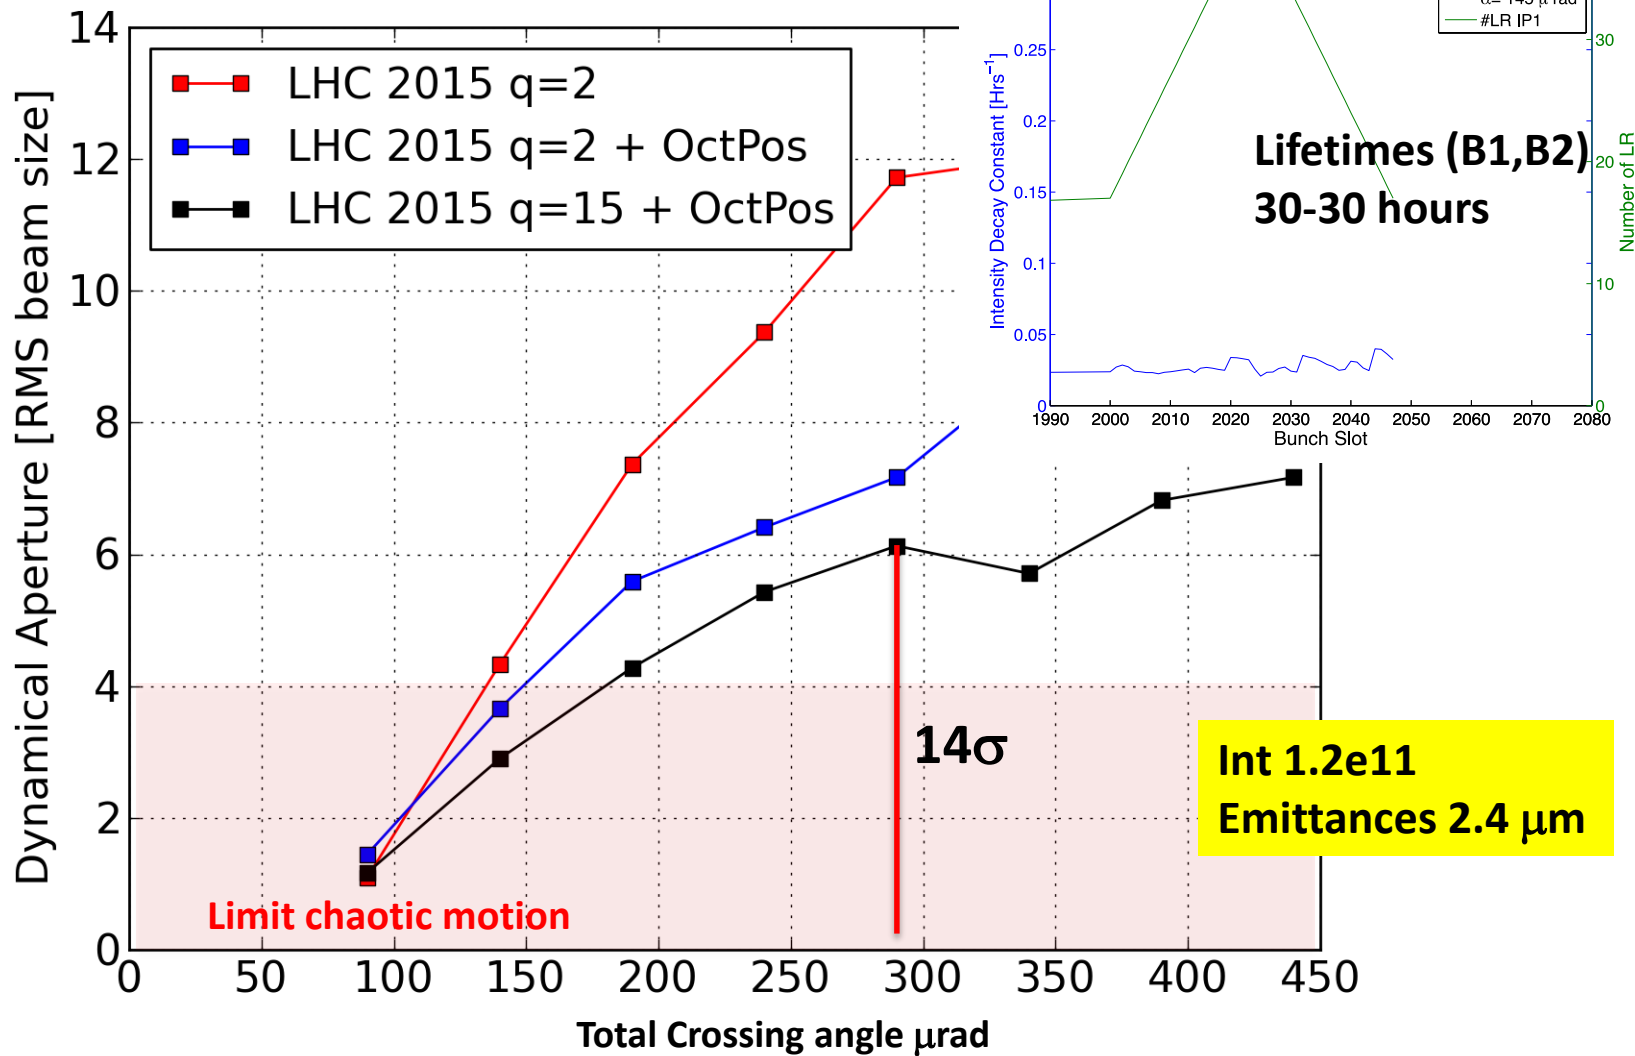

Reducing Q' 15 → 2 units

Landau Octupoles from 476 → 0 A

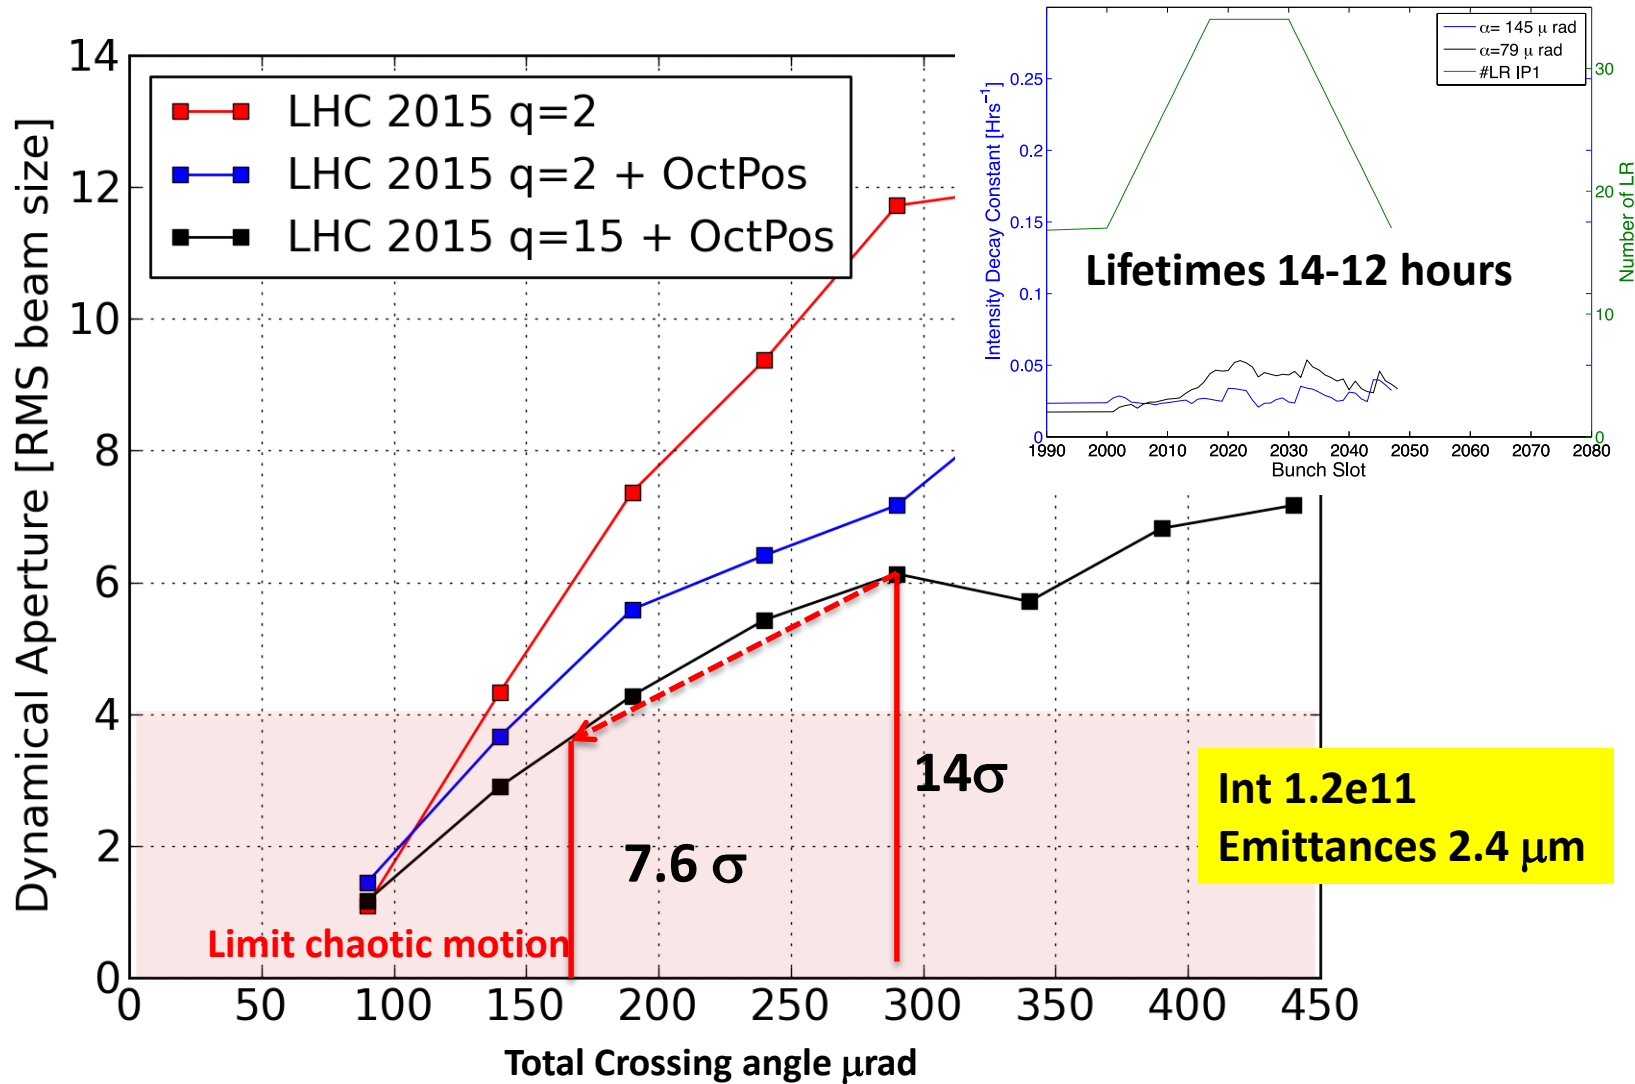

Lifetimes improves going back to 30 hours

2015 MD

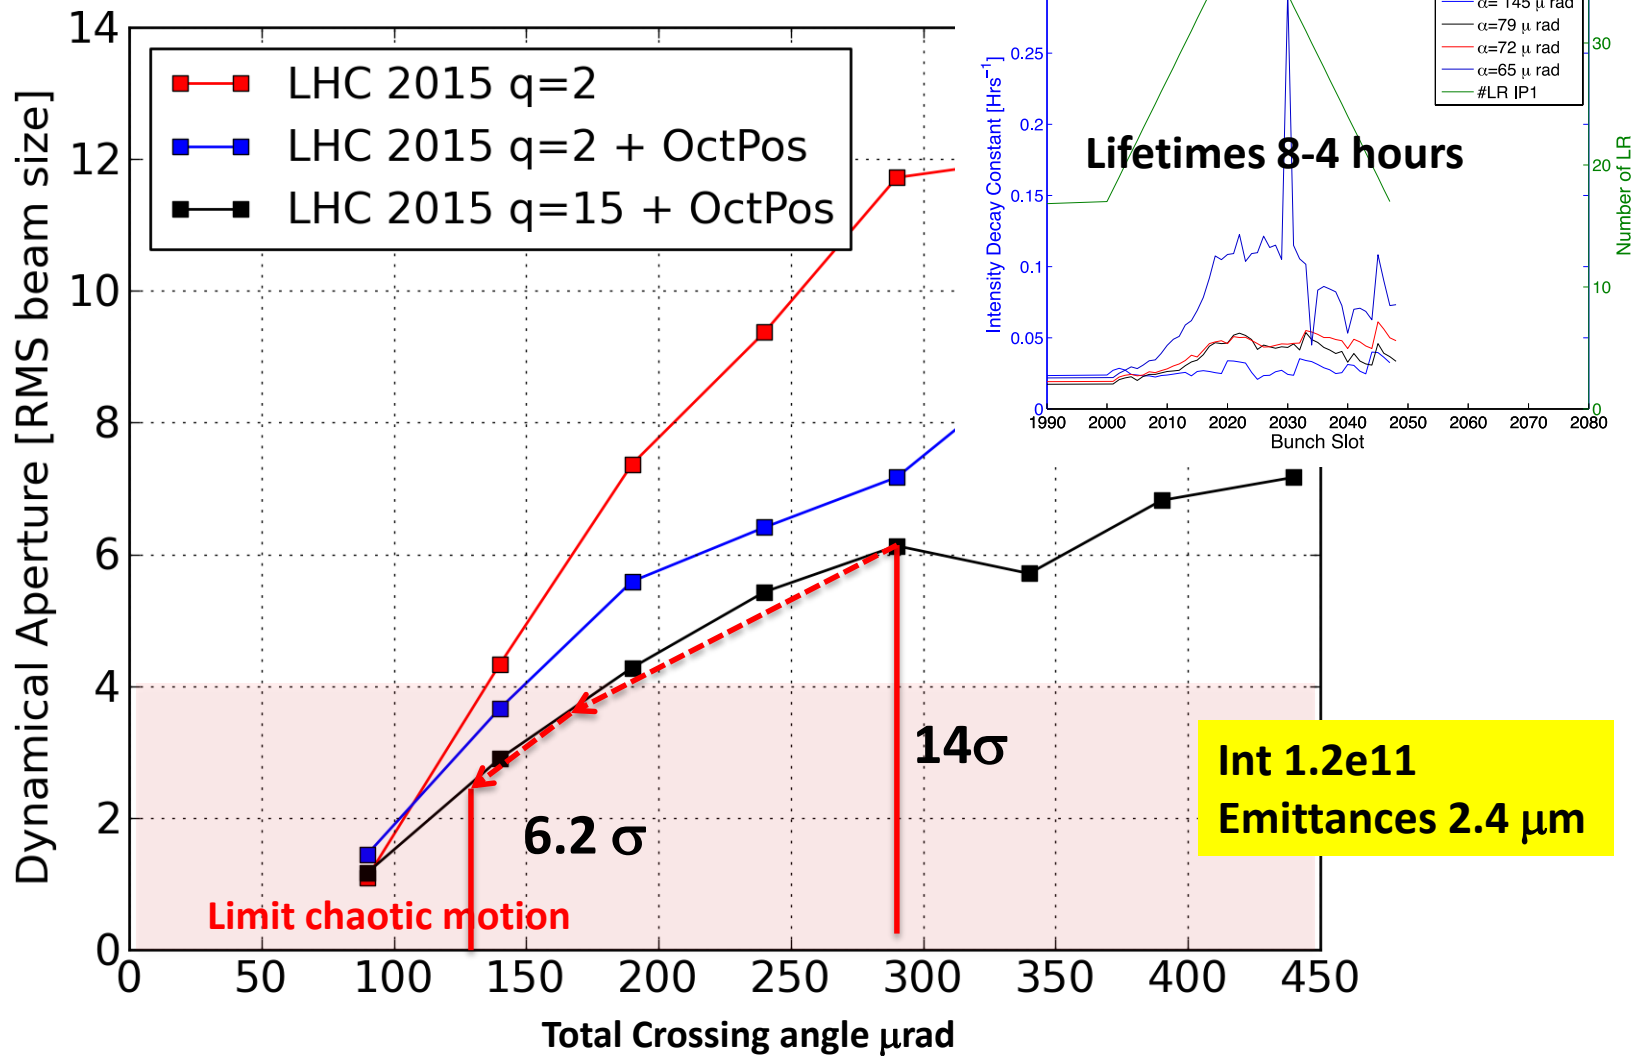

No Evidence of Long Range beam-beam dependent lifetimes

2015 MD

Onset of losses starts between 174-158 μrad equivalent to 8.4-7.6 σ beam-beam separation at first LR encounter \rightarrow consistent with previous observations 50 ns (4 σ DA)

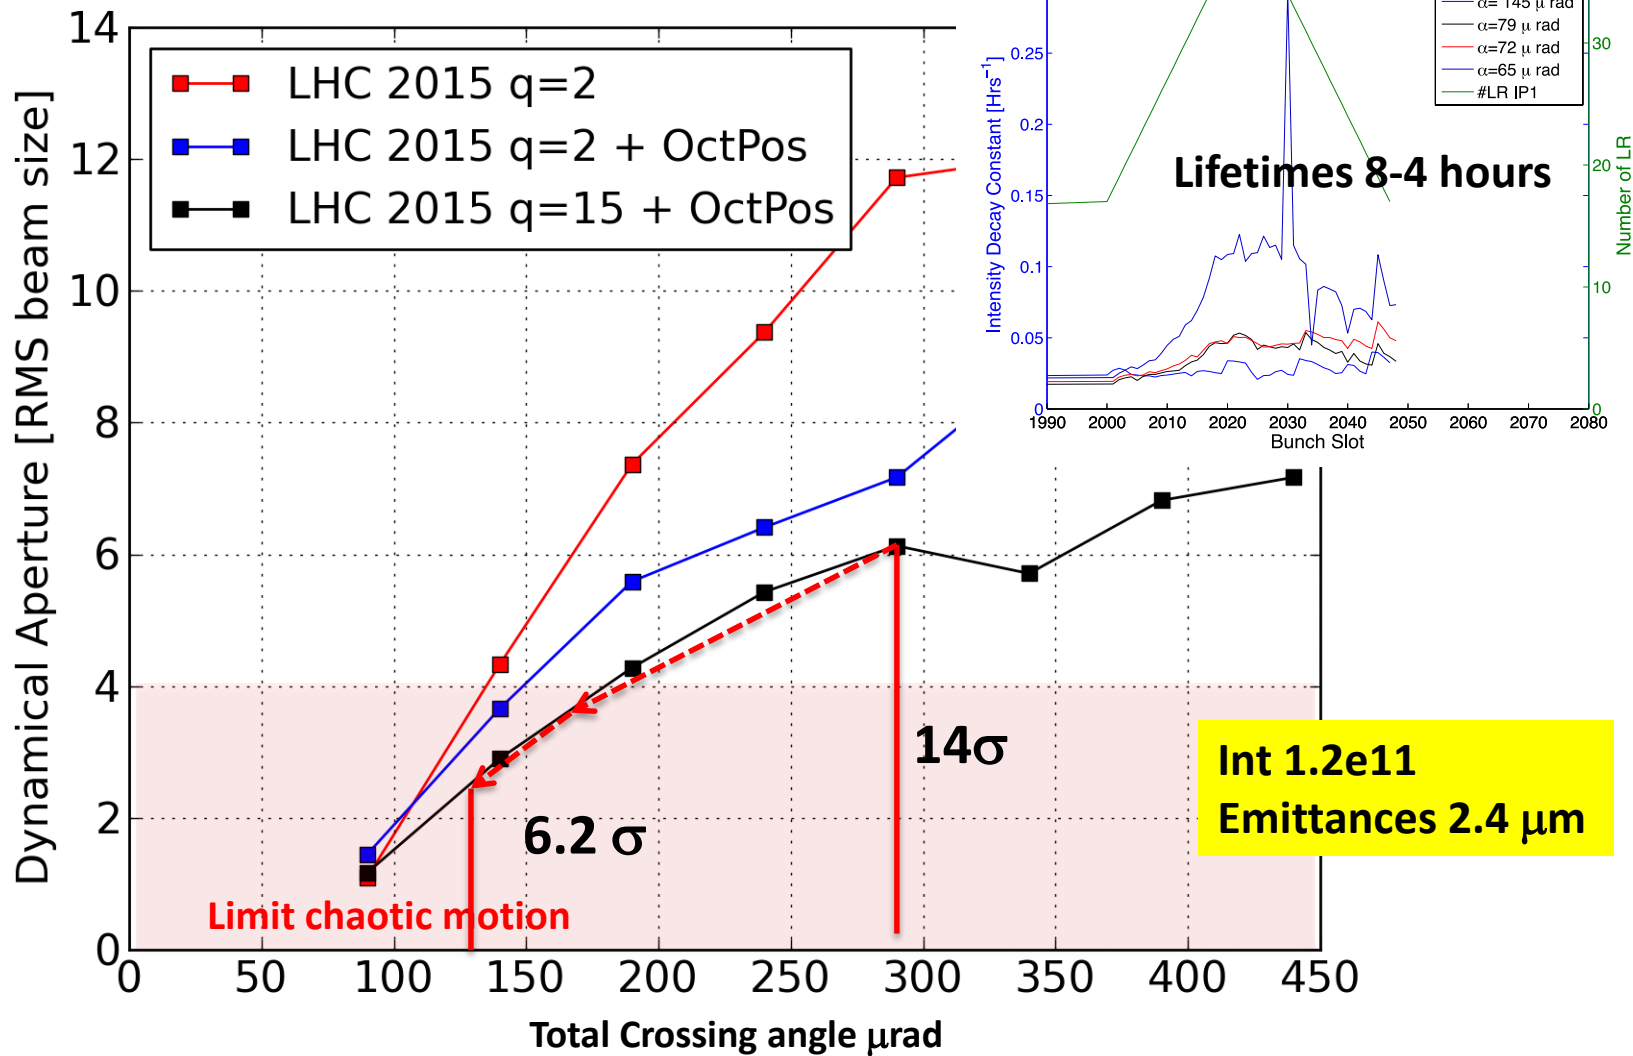

2015 MD

Reduce further the crossing angle to quantify impact on beam lifetimes

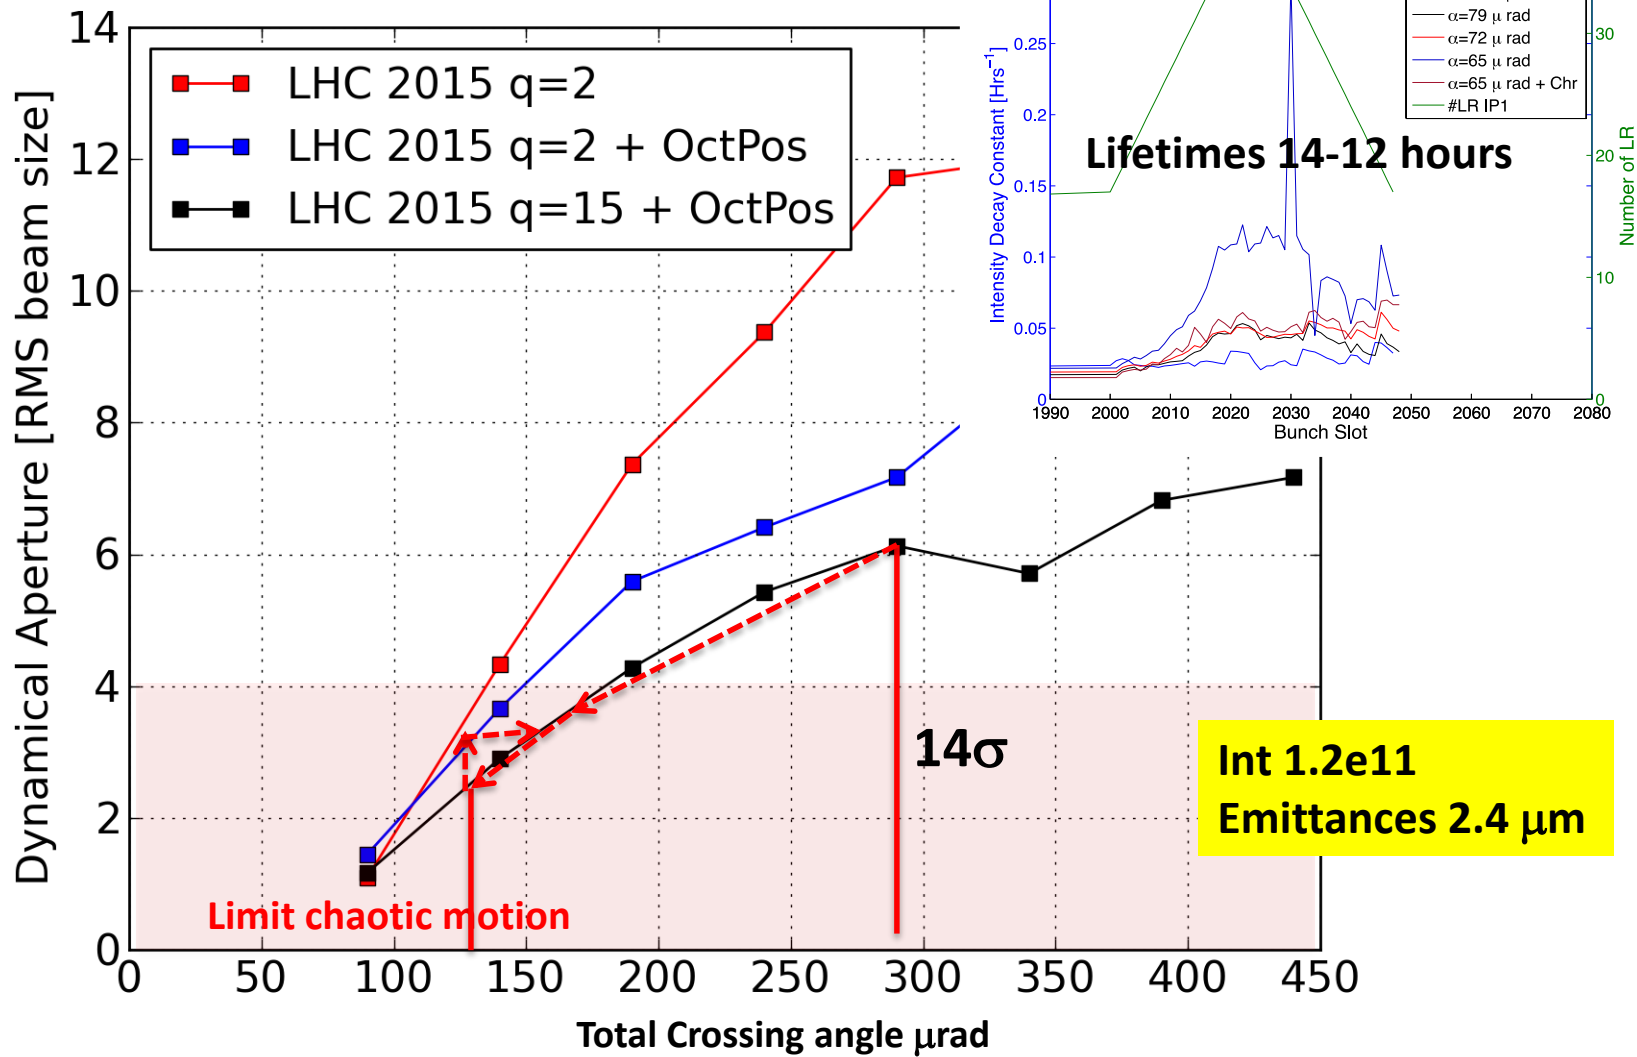

Large losses at 130 μrad equivalent to 6.2 σ separation

2015 MD

Reduce Chromaticity from 15 \rightarrow 2 units + Correct Beam 2 lifetime drop (Feed-Down Effects?)

2015 MD

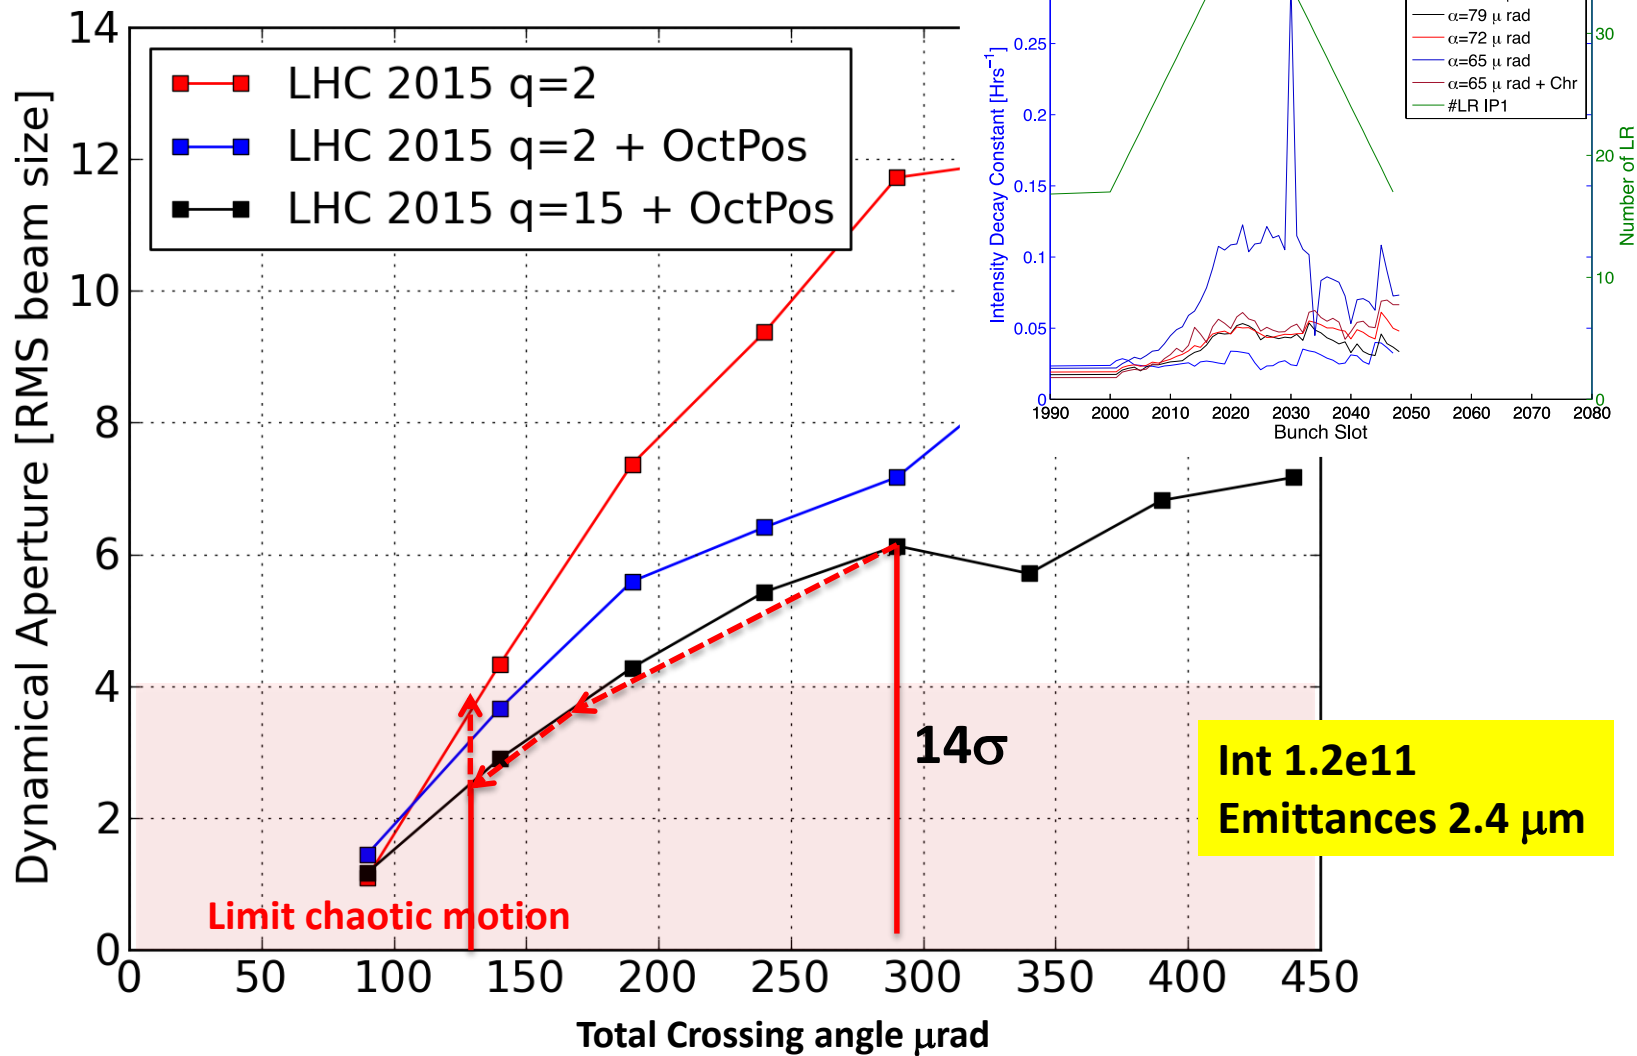

Lifetimes equivalent to case at xing angle 158 μrad

6.3 $\sigma \rightarrow 7-7.5 \sigma$

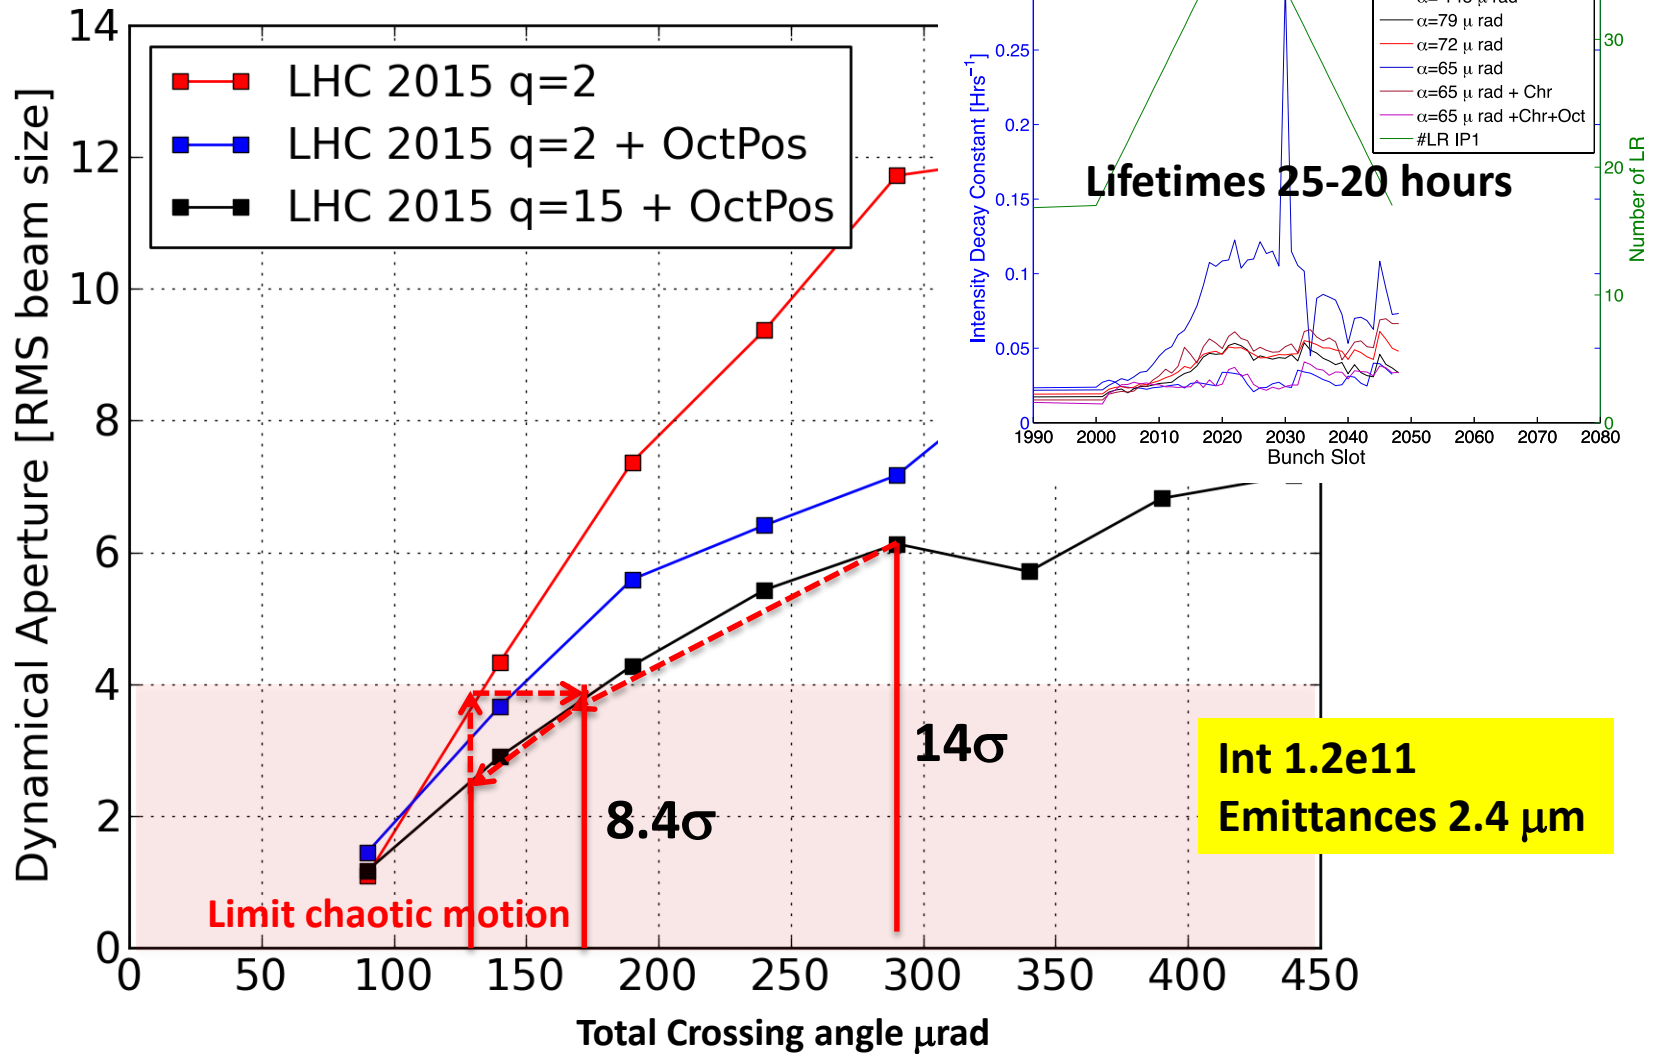

1 σ sep \rightarrow High Q'

2015 MD

Reduce Landau Octupoles to zero current
Colliding beams Rock stable!
Only non-colliding bunch unstable at zero

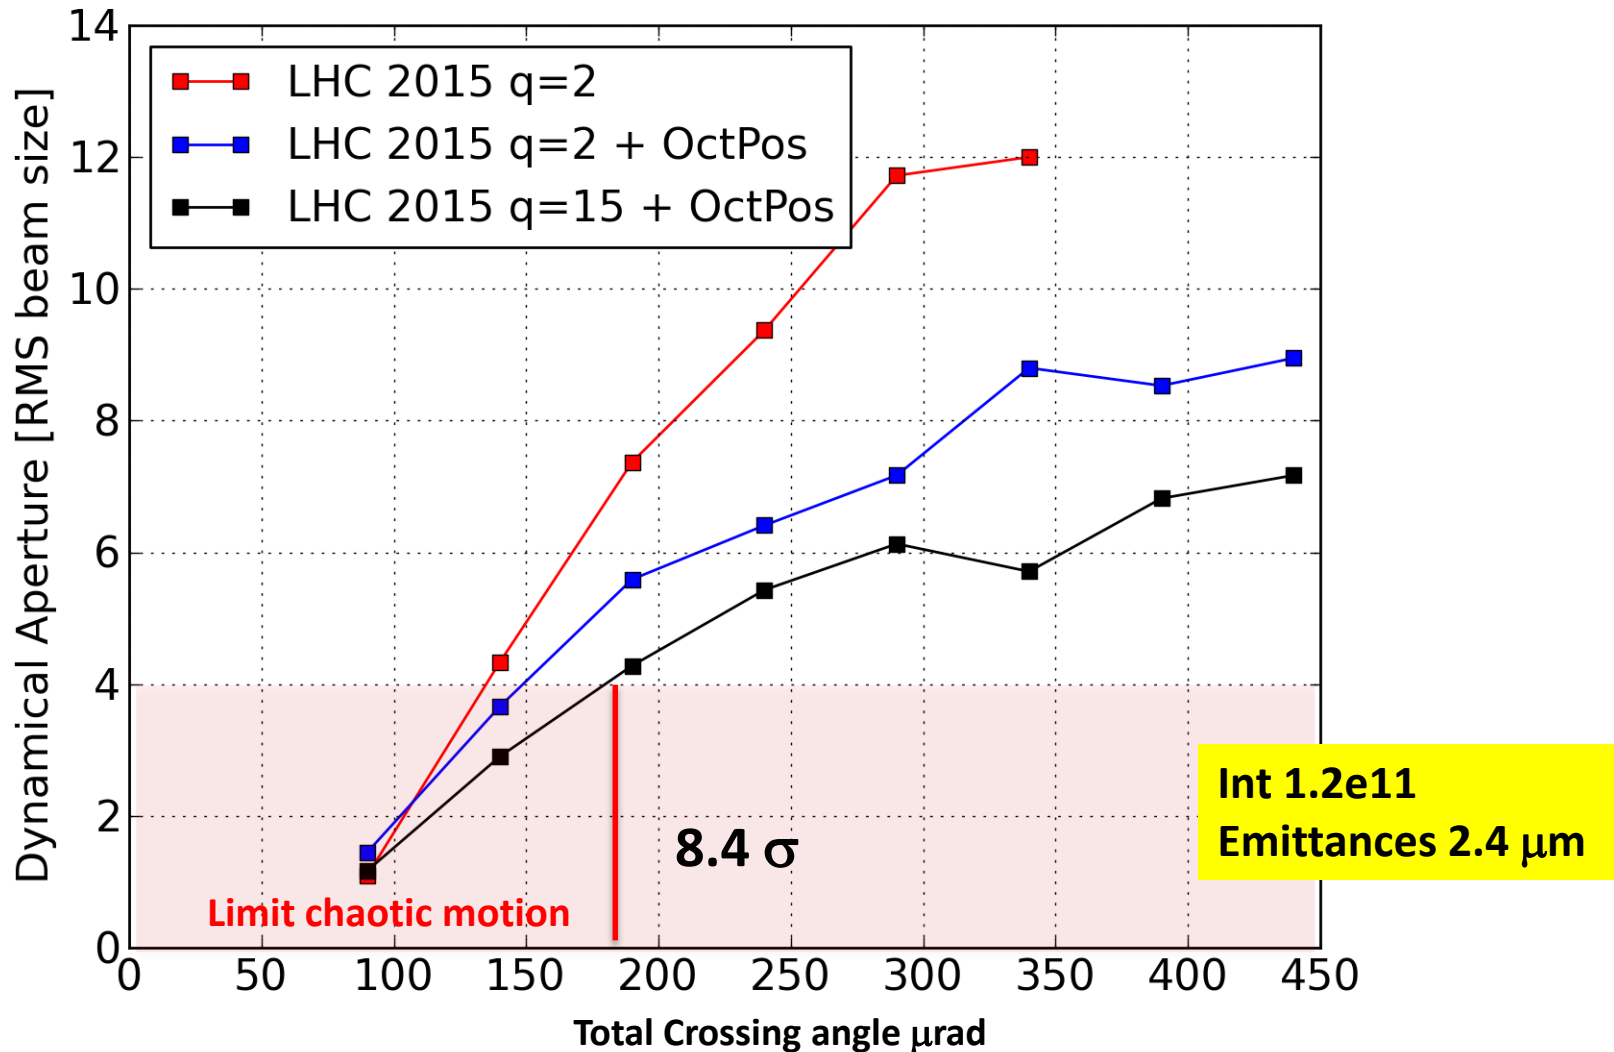

2015 MD

Lifetimes with zero octupoles equivalent to lifetimes at larger xing angle
 6.3 σ sep case + Oct=0 \rightarrow equivalent to 8.4 σ sep case + Oct=476 A

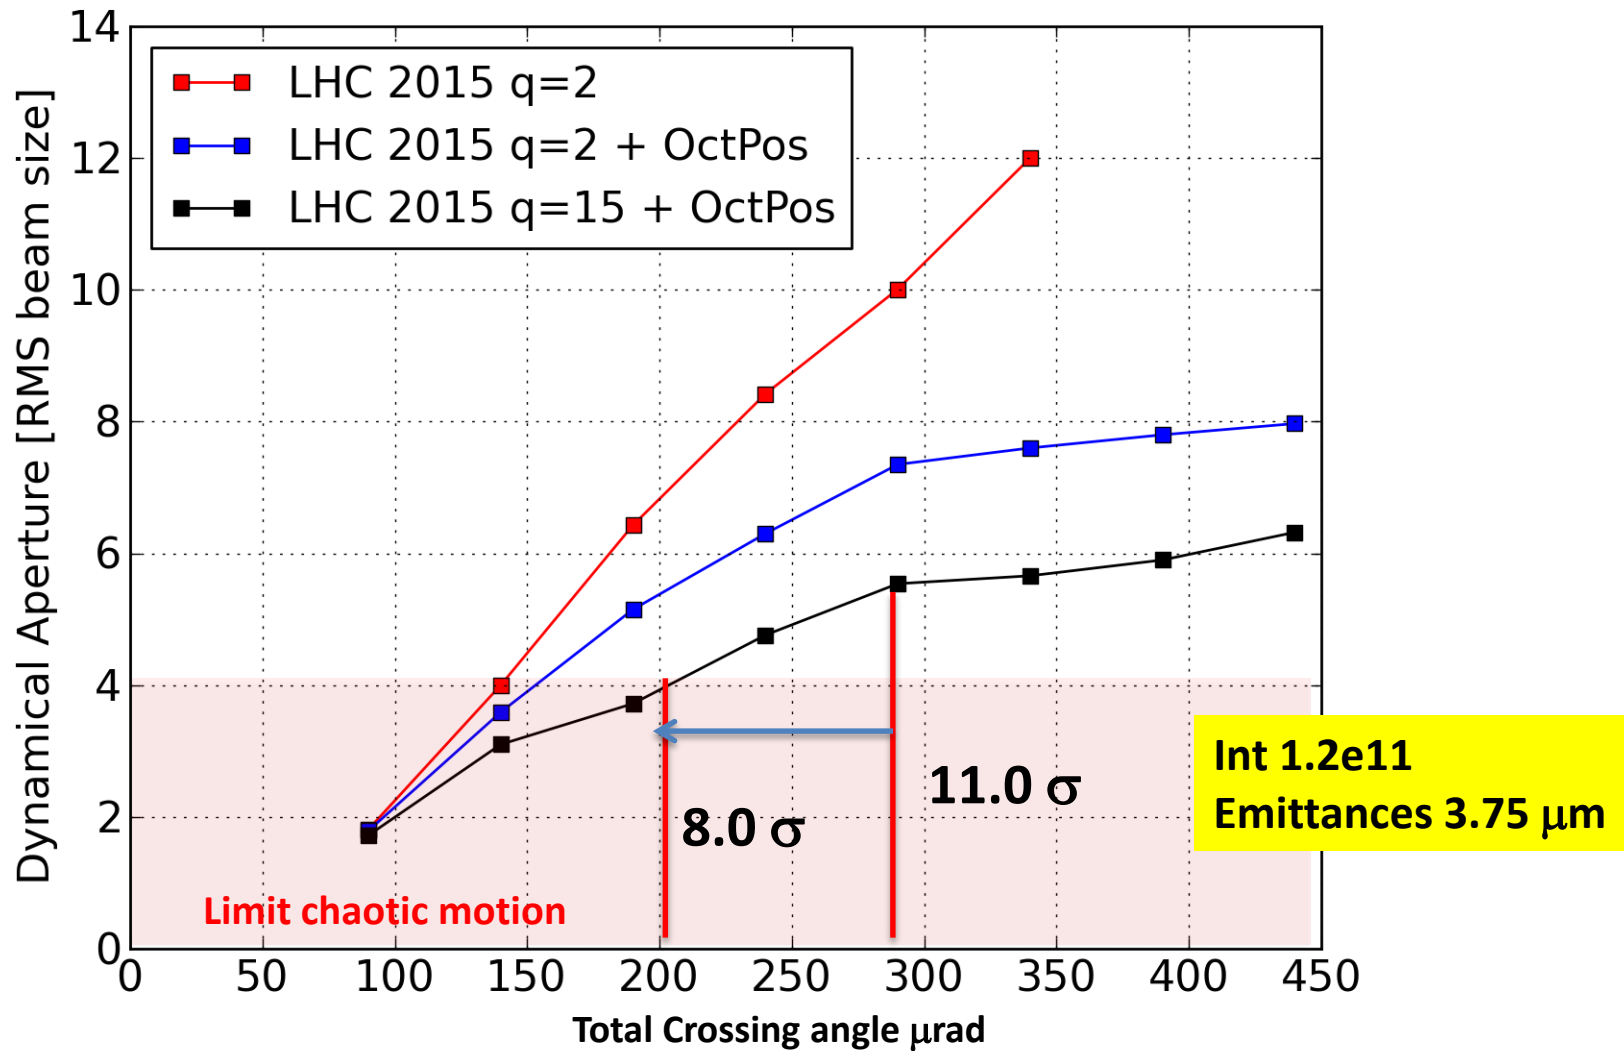

1 $\sigma \rightarrow$ Octupoles

2015 MD

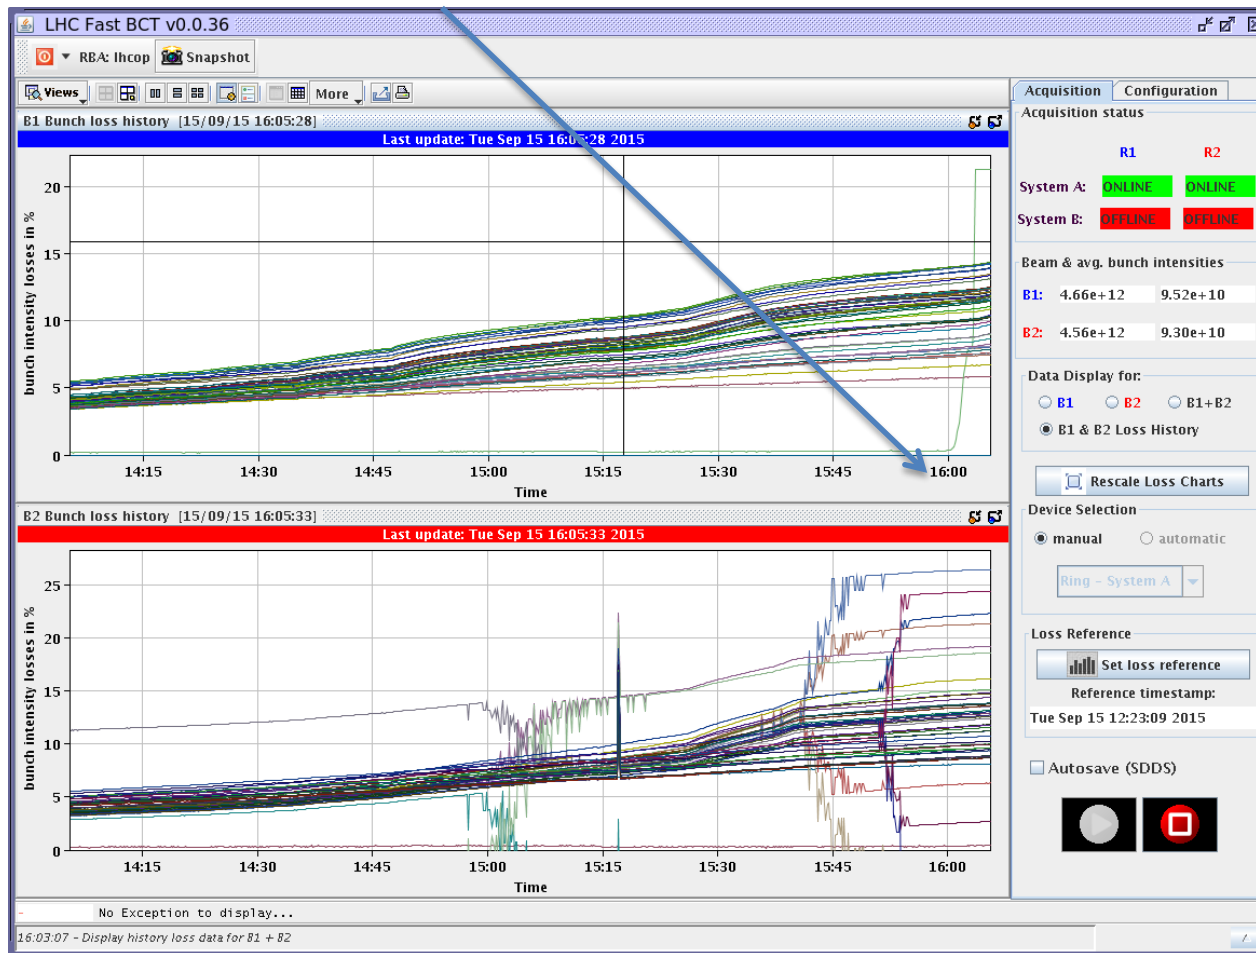

8.4 σ Beam-Beam separation + Oct + 15 units Q' equivalent to 4 σ DA
Beam and Lumi lifetimes are reduced: below 10 hours for smaller angles
Operational beams (3.75 mm emittances) are 2.6 σ away from this limit

2015 Strategy: 6 σ DA for 3.75 emittance beams

6 σ DA criteria robust for commissioning phase (e-cloud, instabilities...)
Smaller Separations possible with Octupoles and Q' reduced in stable beams!

Non-colliding bunches

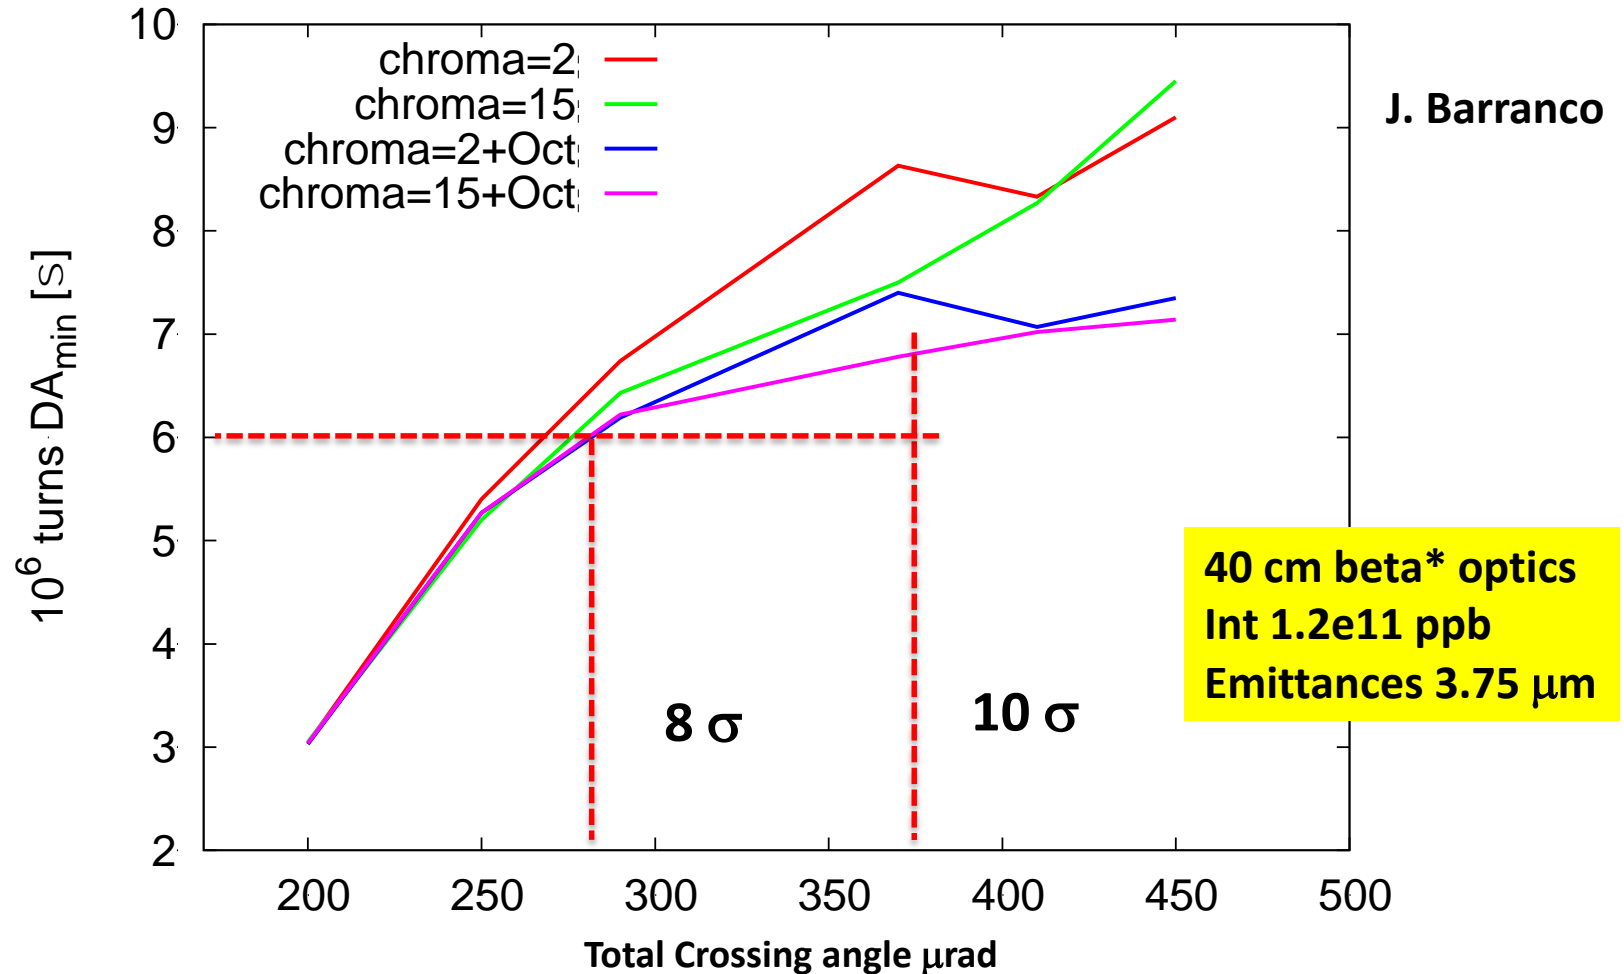

Q' at zero and Octupoles reduced to zero current
Colliding bunches rock stable - **Non-colliding bunches unstable.**
We should aim at reducing Q' and Landau Octupoles in stable beams!

Outline

- 2012 Beam Beam effects data and simulations

 - Beta-beating
- Summary

2016 Xing angles IP1&5: Dynamic Aperture

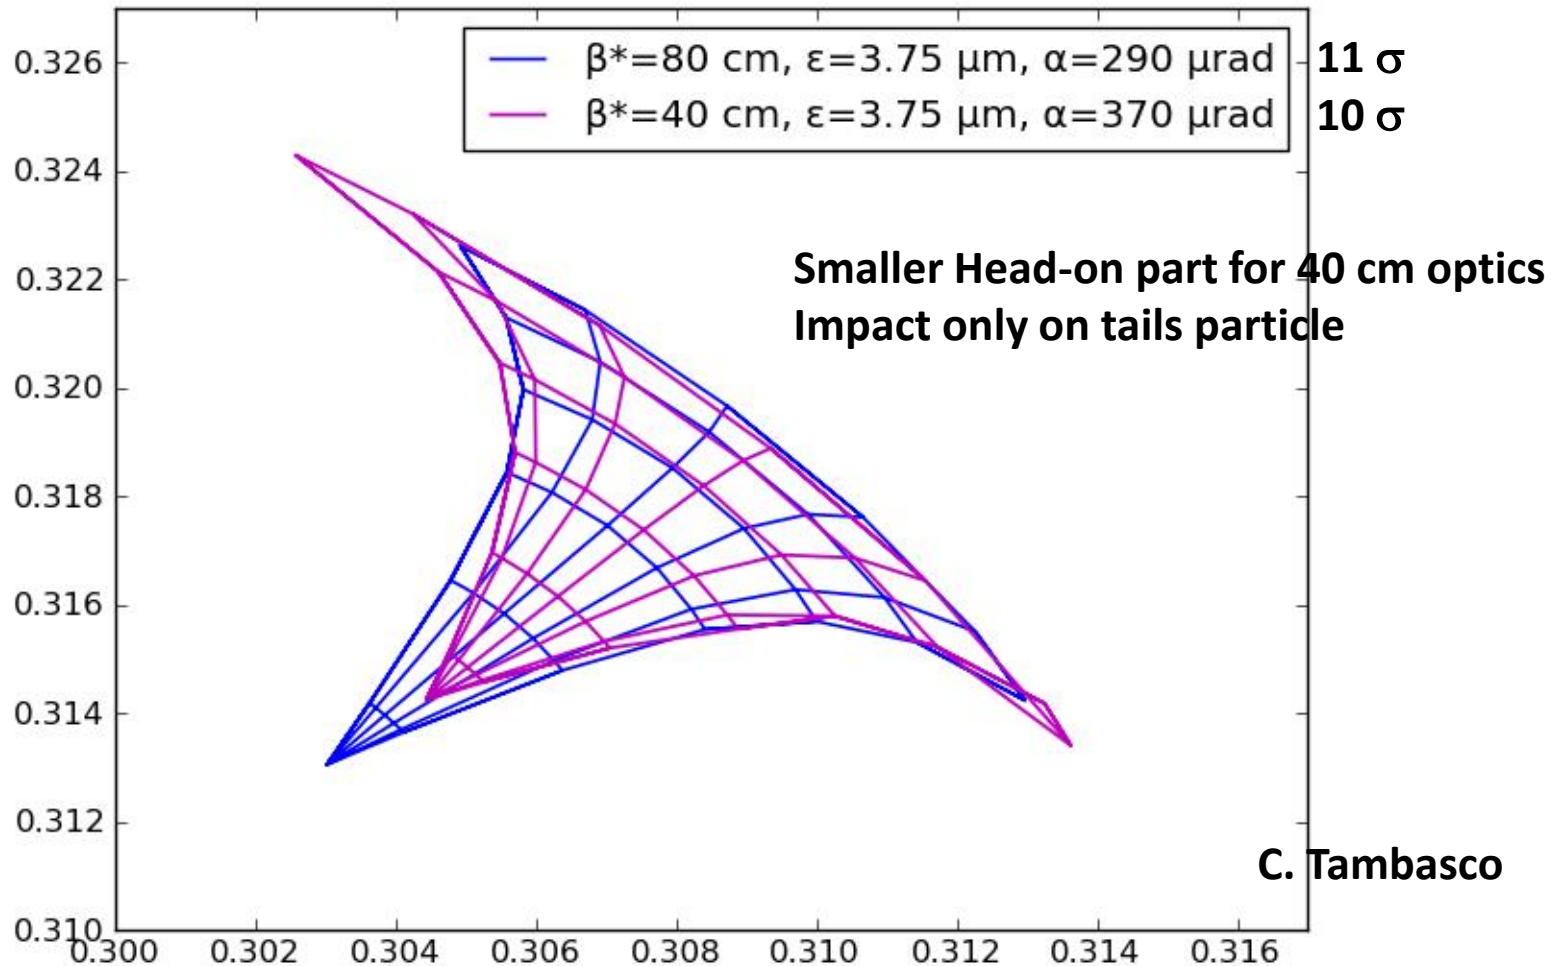

DA above 6σ with margins to allow for $1.3e11$ ppb

Possibility to reduce angle only when:

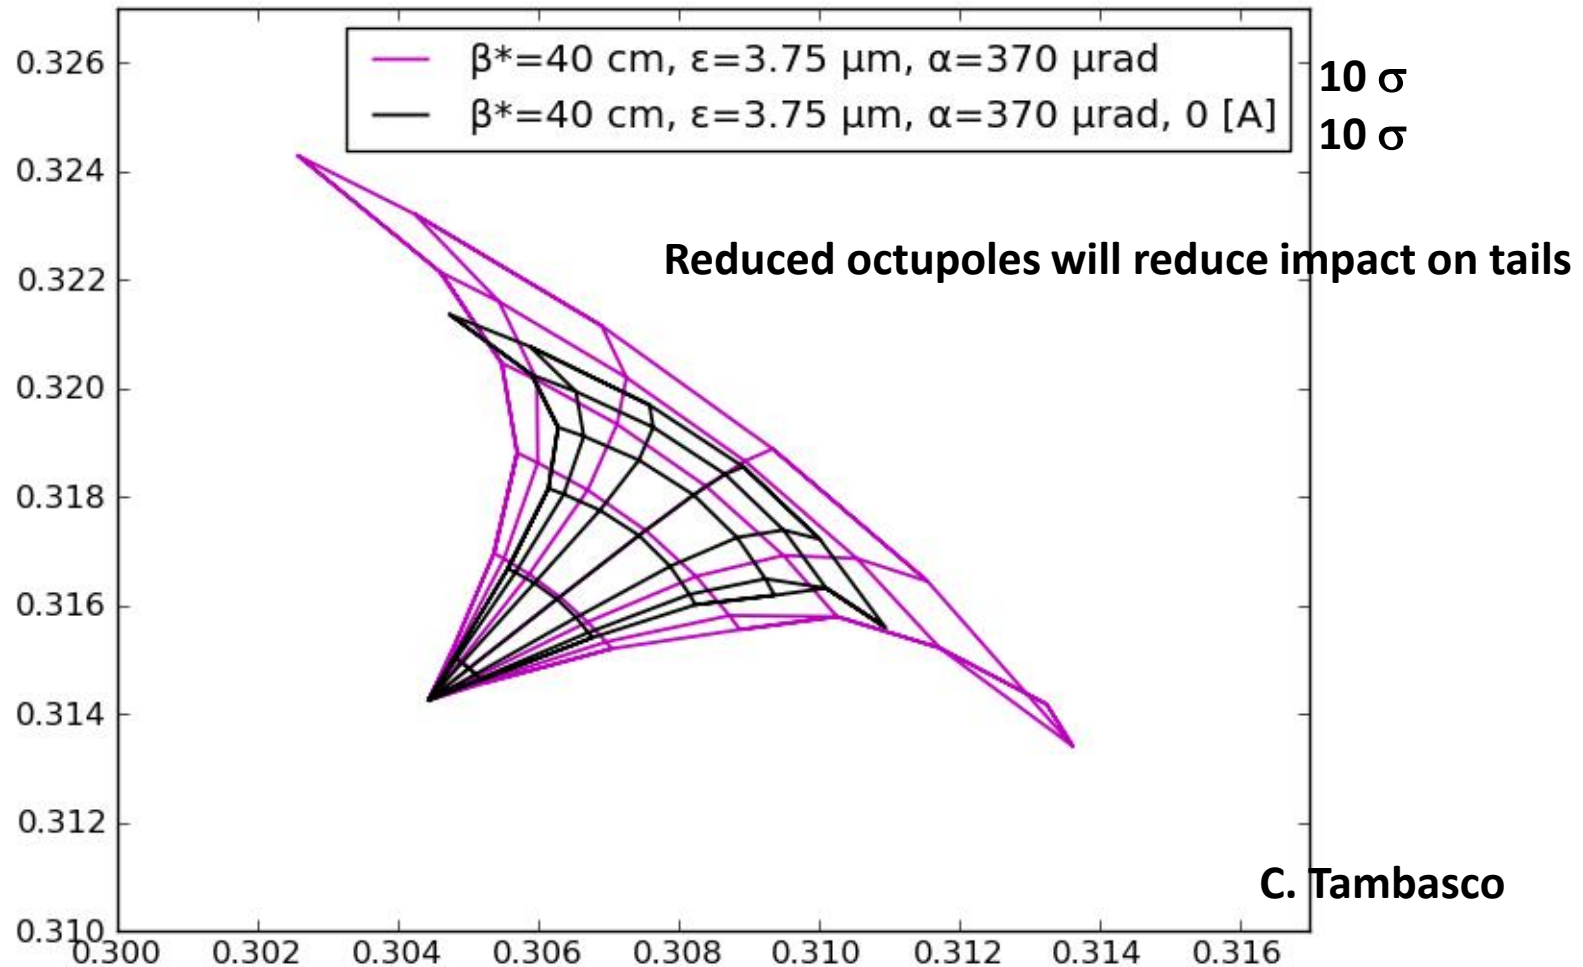

- beams emittances are stable (e-cloud, instabilities)
- Octupoles and Chroma reduced
- MD on crossing angles

2016 Xing angles IP1&5: Footprints

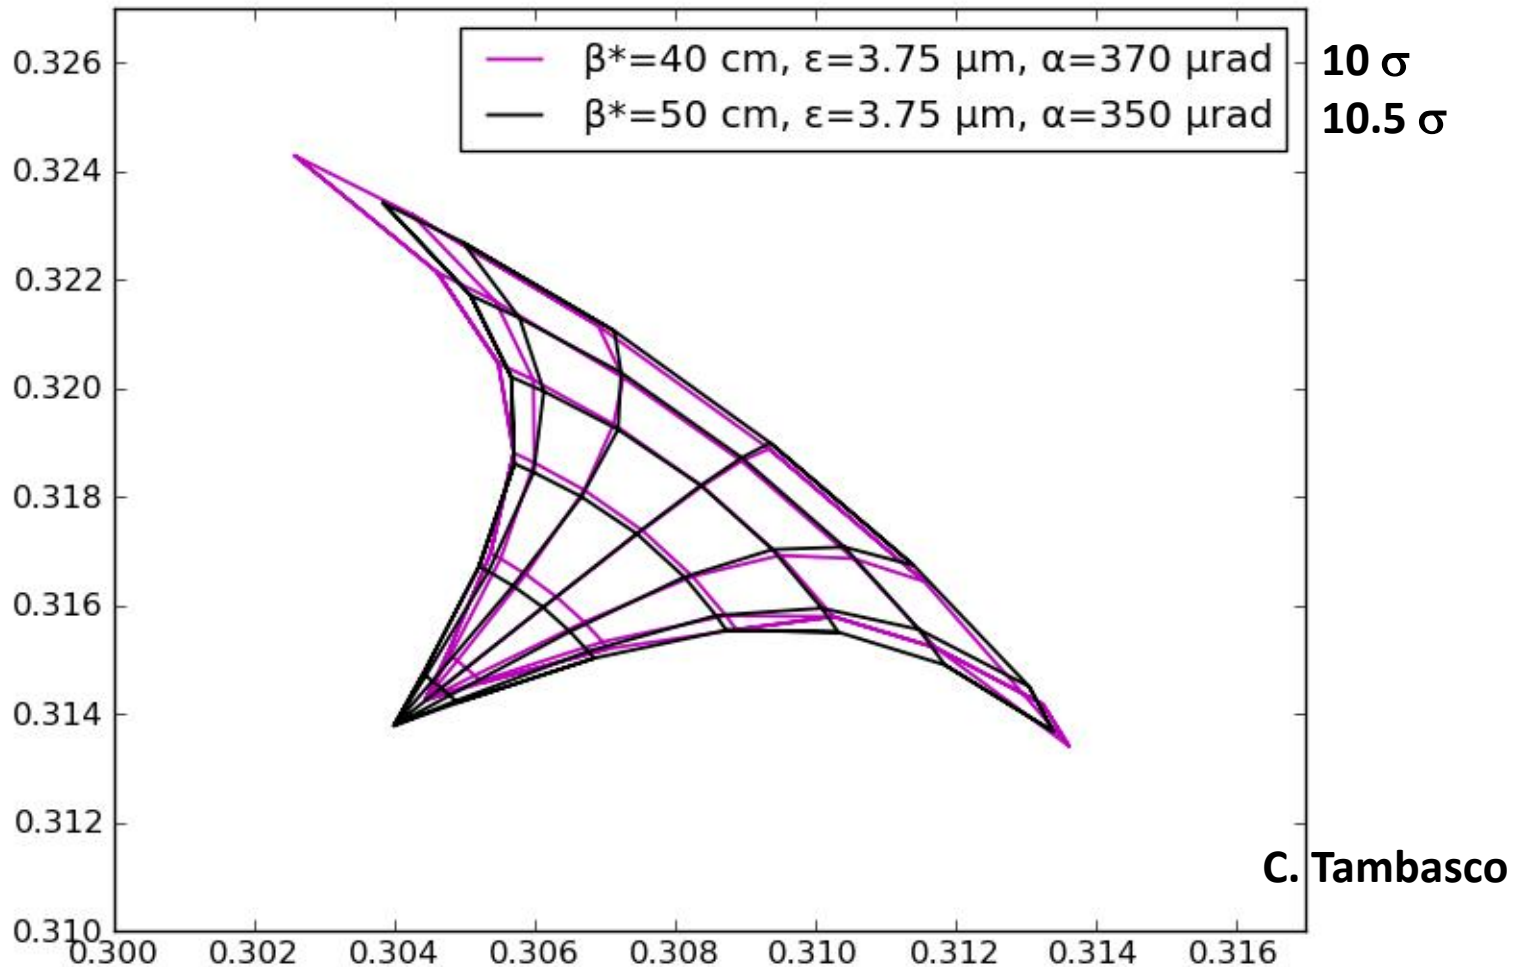

2015 versus possible 2016 with 10 σ separation with 40 cm optics

2016 Xing angles IP1&5: Octupoles effect

**Reducing Landau octupoles reduces the whole spread on tails
→ Similar situation as 2015**

2016 Xing angles IP1&5: 40 cm versus 50 cm

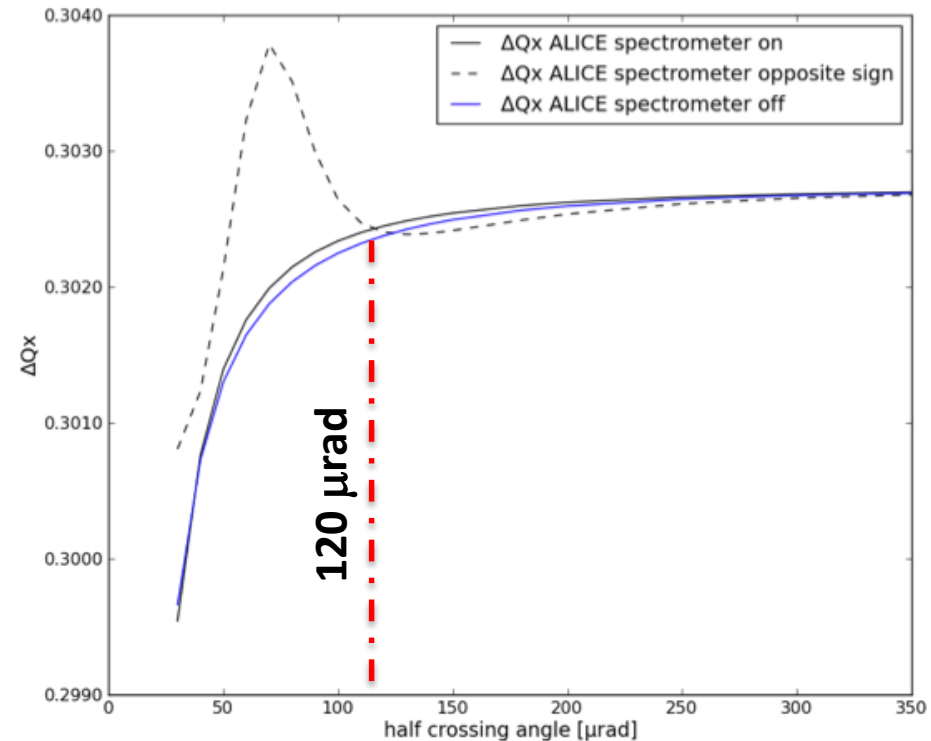

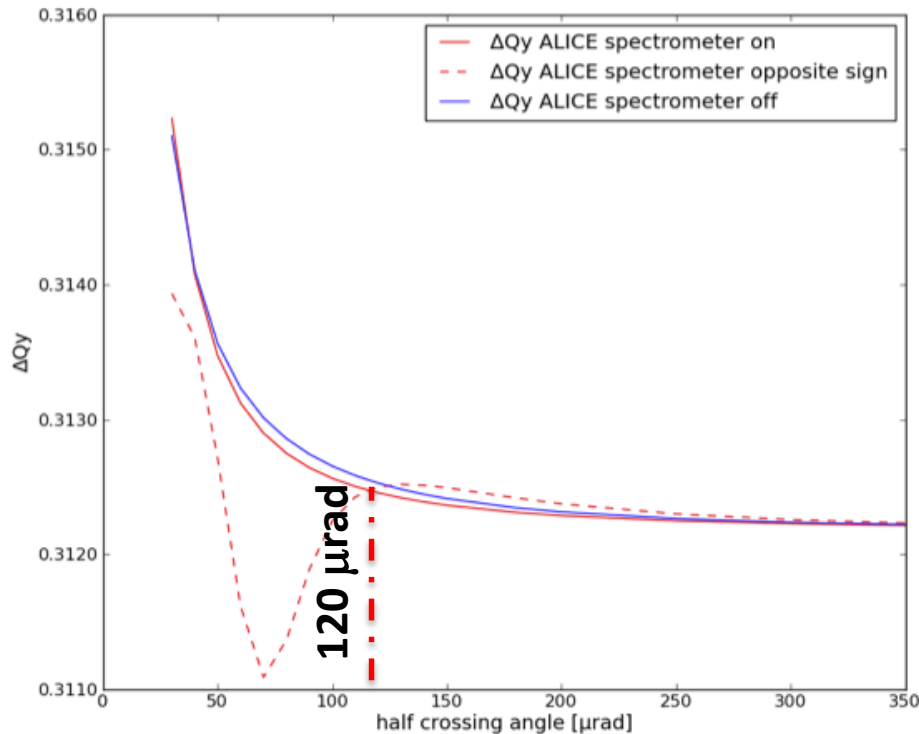

40 cm optics or 50 cm are almost identical for beam-beam effects

Alice IP2:

in shadow of the high Lumi experiments

From DA studies 10^{-3} tune shift can have strong impact on DA (2σ reduction)
→ Tune shift below 10^{-4} effect

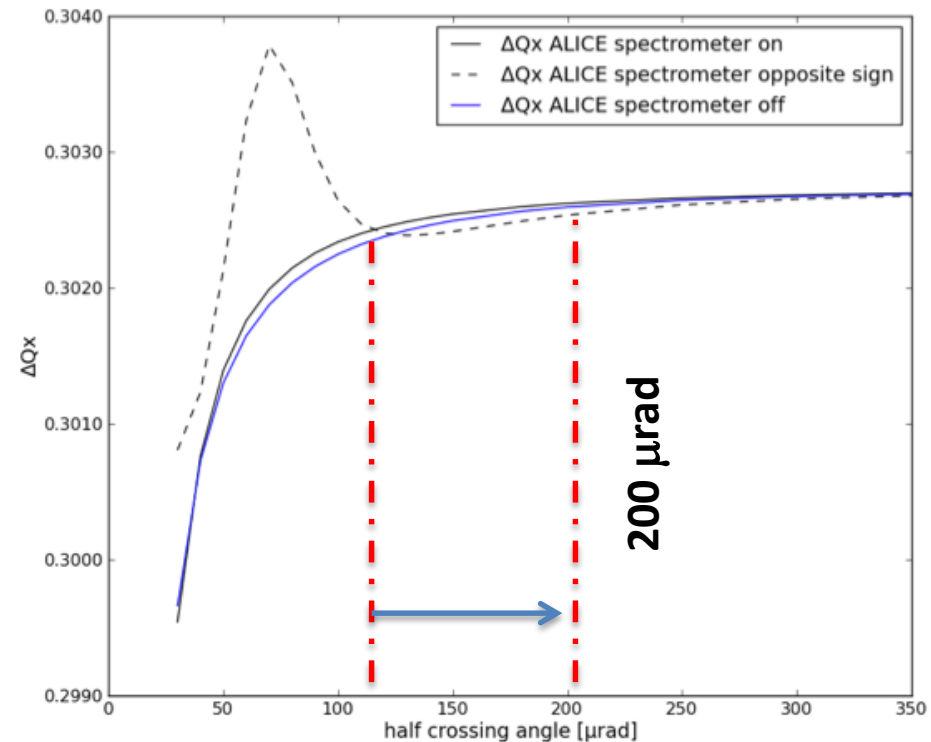

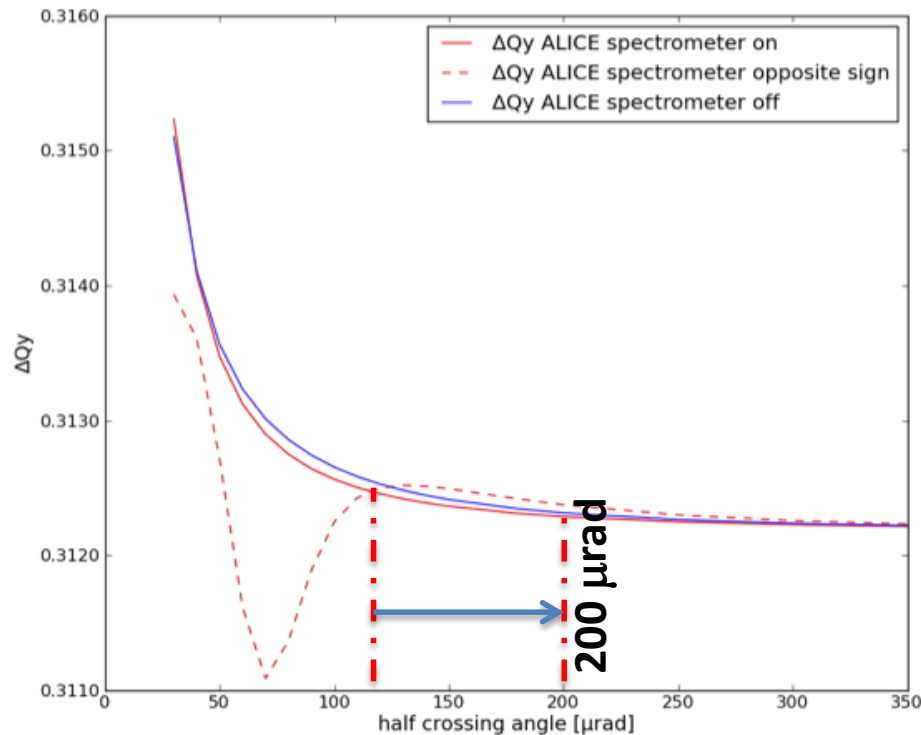

Alice IP2: in shadow of the high Lumi experiments

From DA studies 10^{-3} tune shift can have strong impact on DA

→ Tune shift below $5 \cdot 10^{-4}$ effect

→ for 2016 swap of spectrometer polarity requested

→ Need larger angle (200 μrad half at Collision)

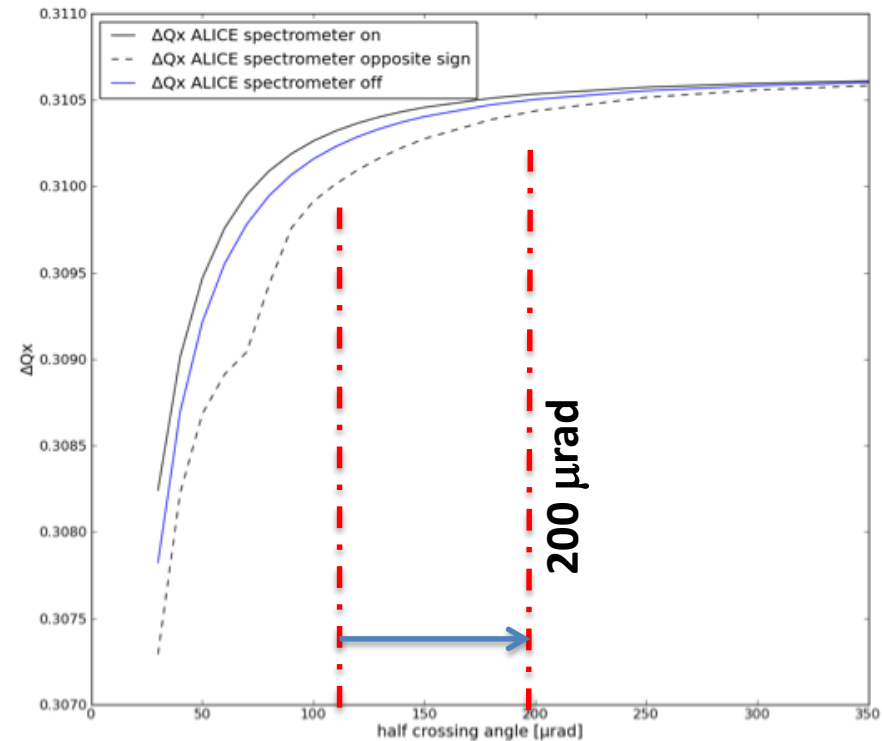

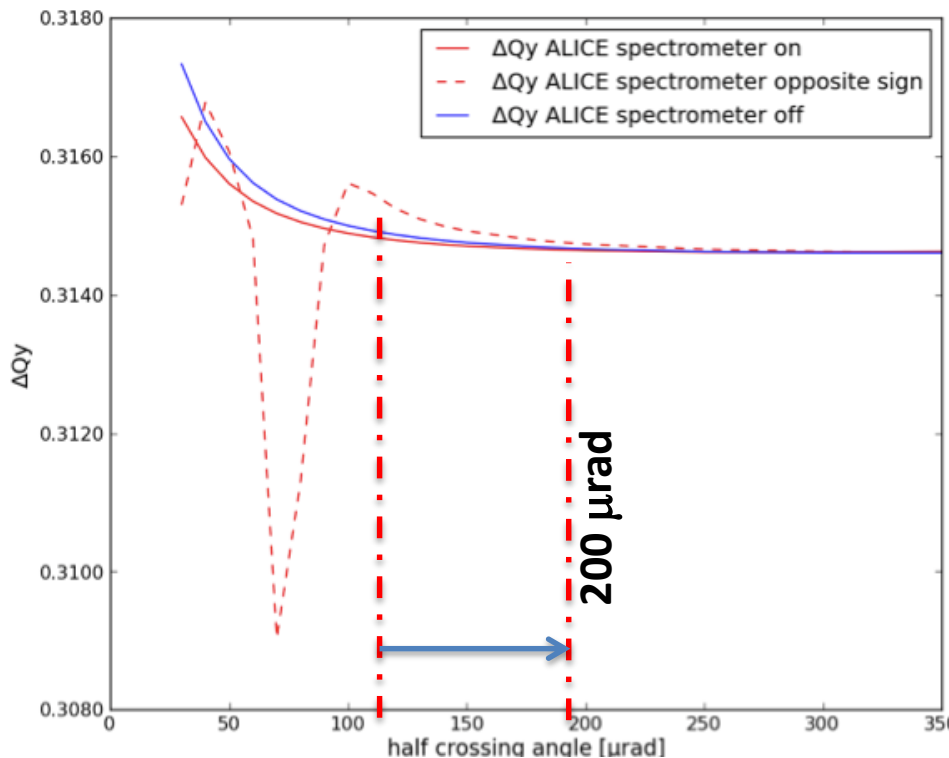

400 mrad external crossing angle

Alice IP2: in shadow of the high Lumi experiments

From reduce impact of long range from these IP

→ Tune spread below $5 \cdot 10^{-4}$ effect

→ **for 2016 swap of spectrometer polarity option**

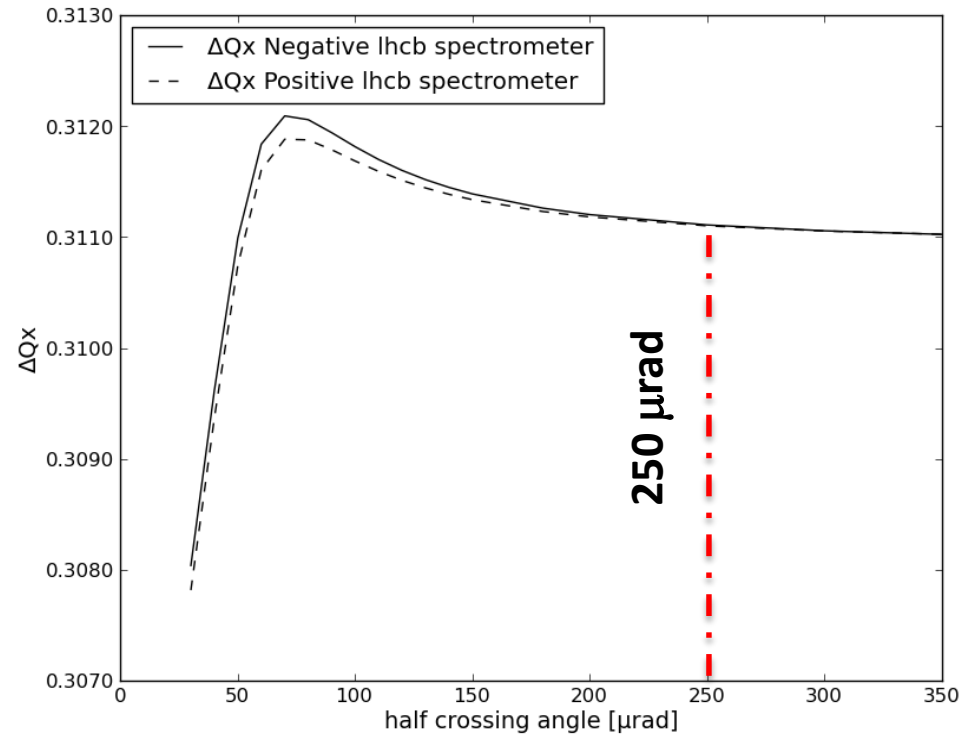

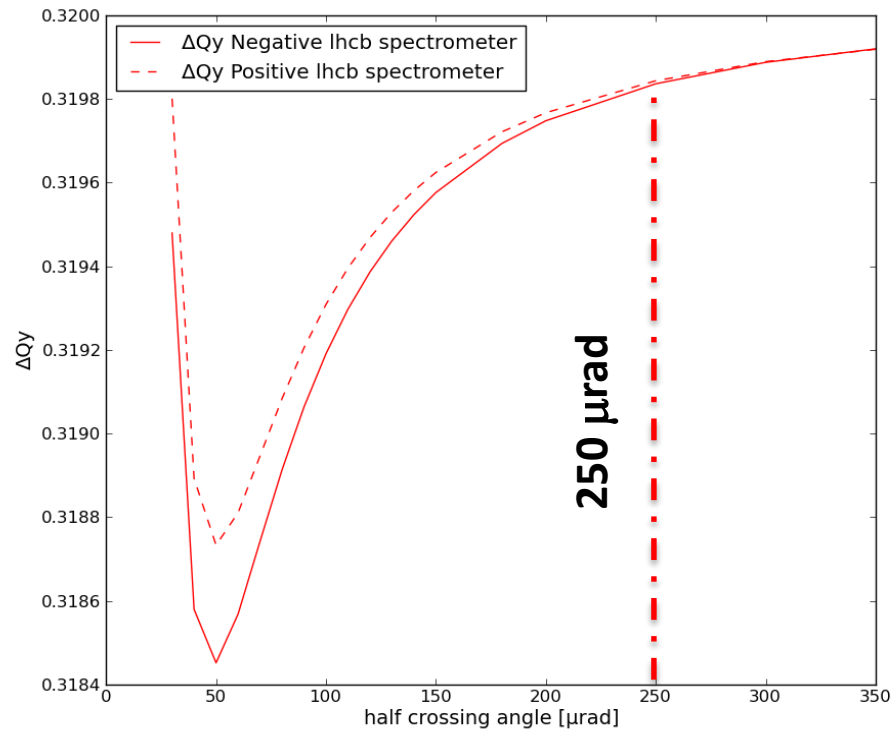

400 mrad external crossing angle

LHCB IP8:

in shadow of the high Lumi experiments

Same considerations set-up as in 2015

→ Crossing angle $250\ \mu\text{rad}$ half

Outline

- Summary

Colliding beams: Stability

Head-on beam-beam is weaker respect to 2015

→ factor 2 reduced BB parameter from 0.0067 → 0.0033/IP

→ reduced Landau damping depending on separation

Three cases of coherent oscillations in stable beams:

1) Fill 4321 instability in stable beams Beam 1V in squeeze then Beam 2 V in stable beams

→ **Weak-strong regime**

2) OP-scans and ADT reduced gain (several Fills) → instabilities at separation of 2σ

→ **Weaker beam-beam parameter (head-on Landau damping)**

3) BCMS beams test

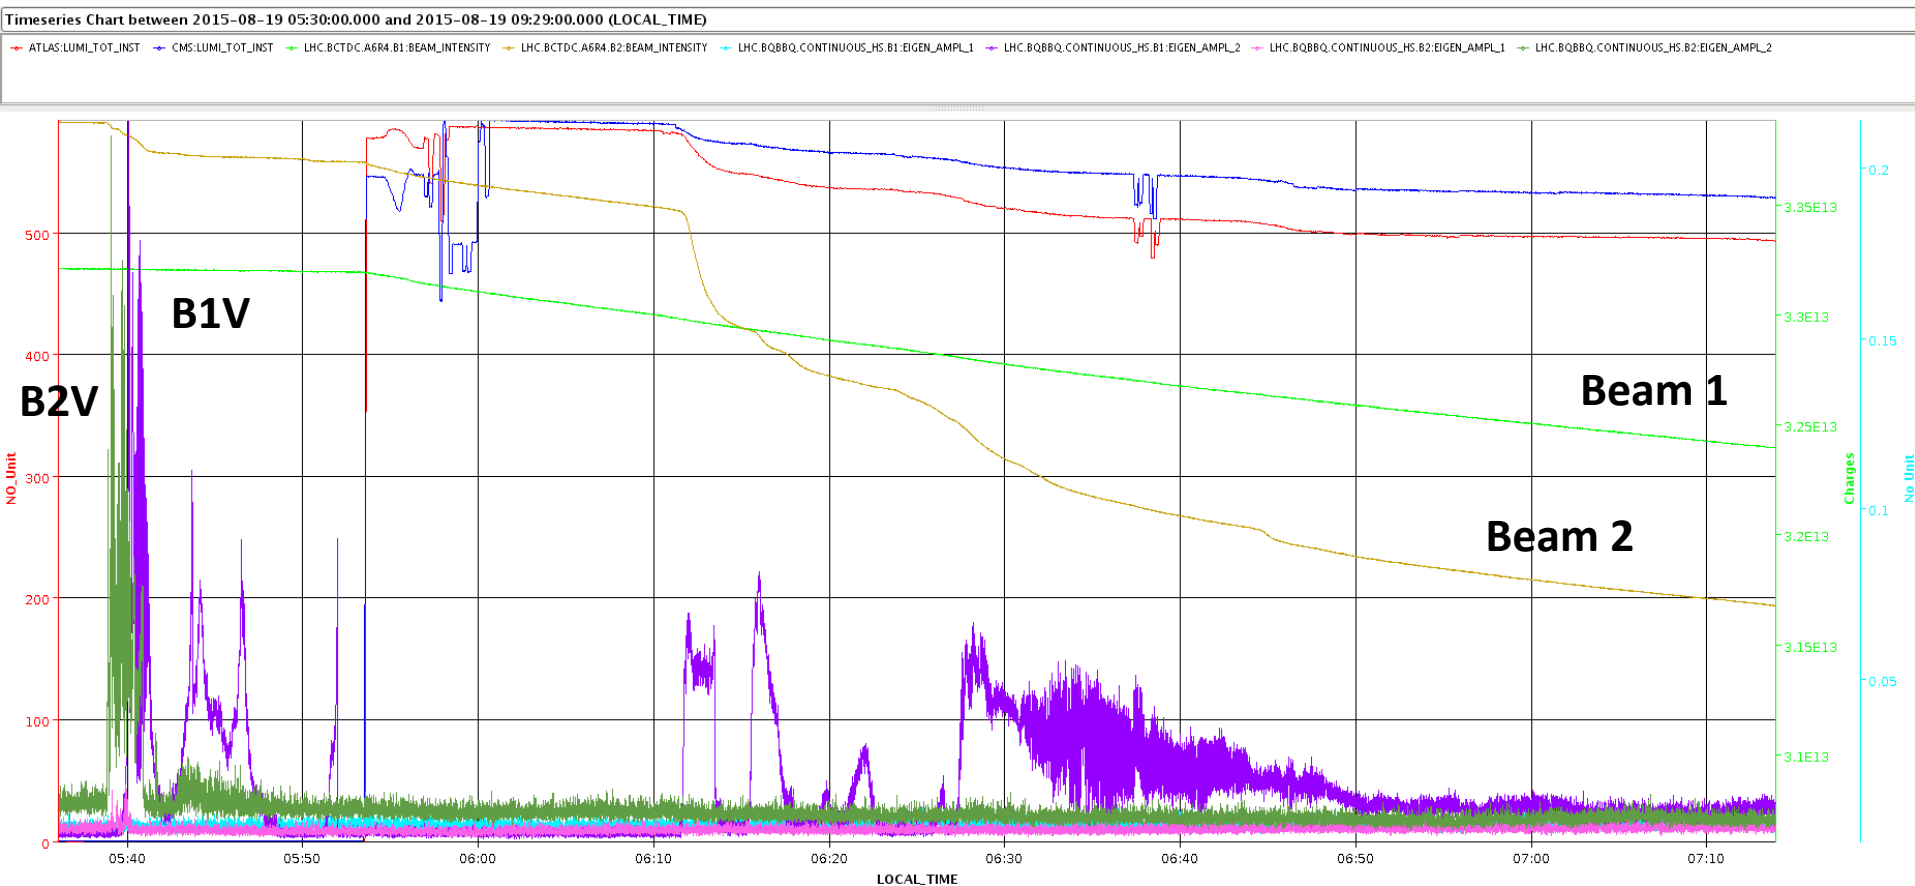

→ **Coherent oscillations during stable beams** → could be like for Fill 4321 (weak-strong regime) since instabilities observed during squeeze (**L. Carven talk**)

Fill 4231: Instabilities during squeeze and impact in collisions

Instability in the squeeze (9m-3 m):

Beam 2 Vertical (green line) then Beam 1 Vertical (violet line)

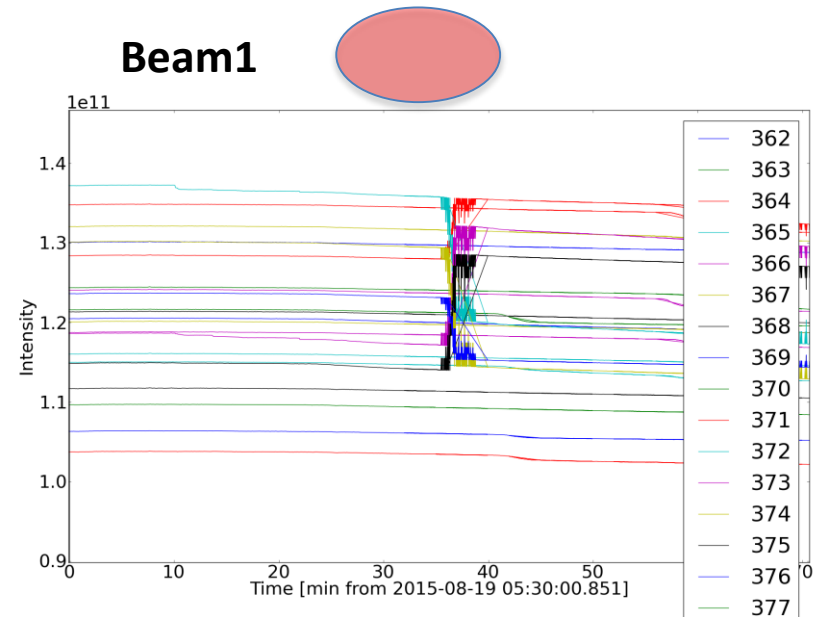

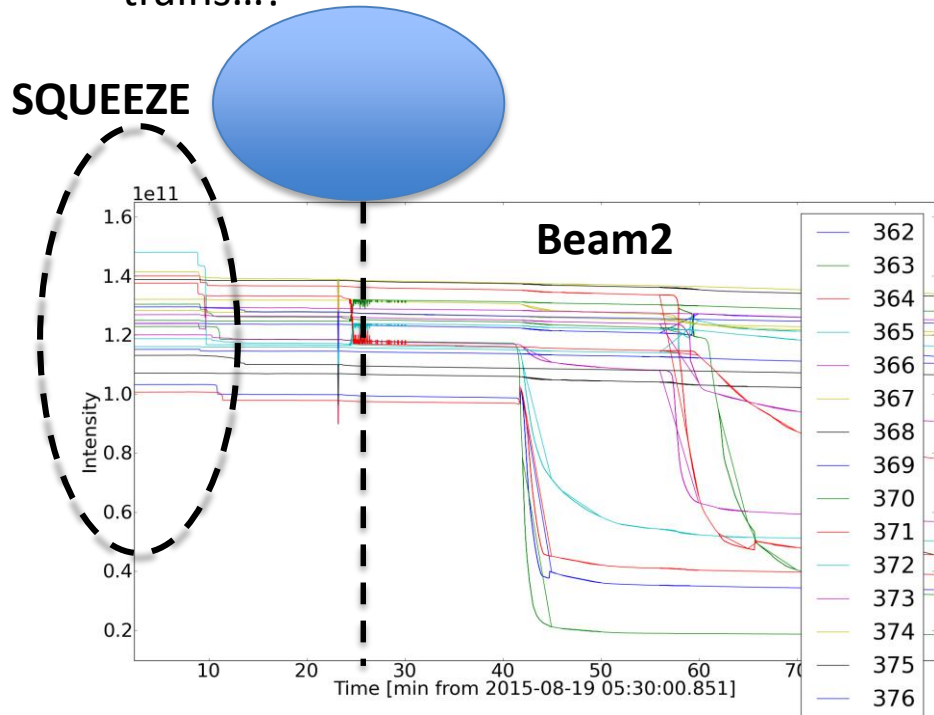

In Collision only Beam 1 Vertical shows coherent "oscillations"?

Bam 2 Losses Unstable Bunches

B2 V unstable in Squeeze 1st TRAN of 72 bunches most affected then few individual bunches in other trains

Why? No BB apparent reason, these bunches are like all the central ones in other trains...!

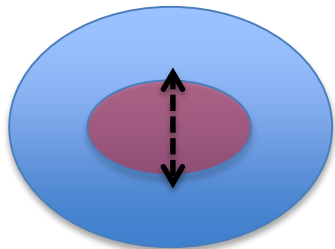

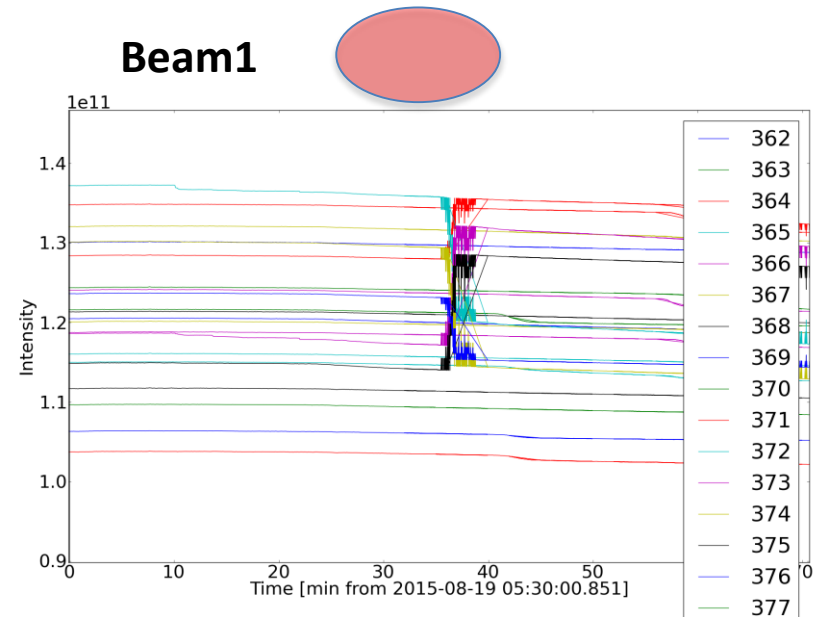

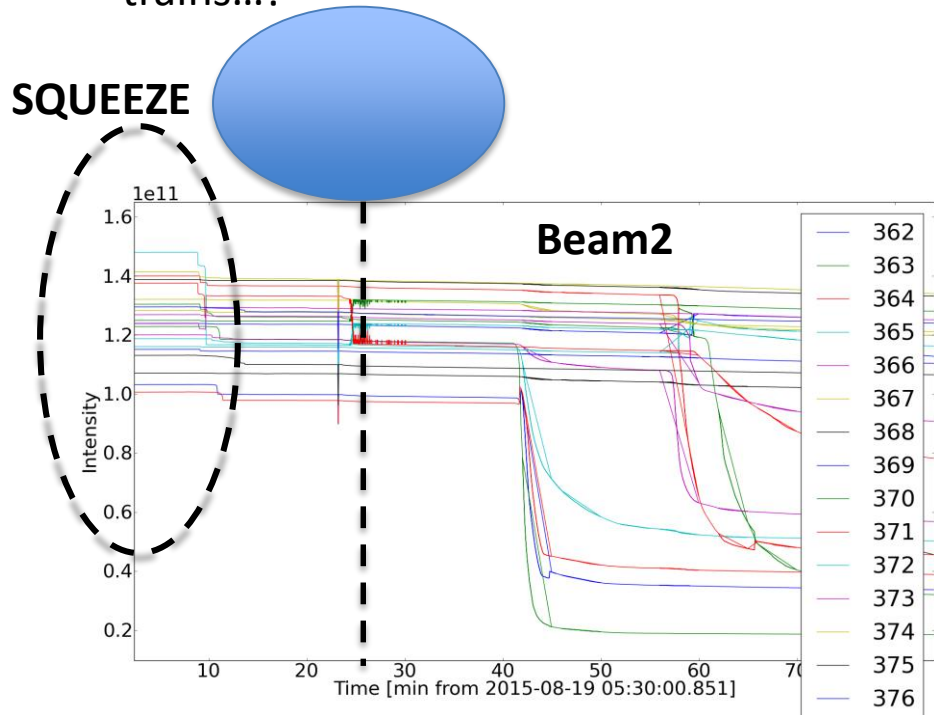

Beam 1 sees BB parameter 0.001 → like “single beam” in squeeze
Oscillations and emittance blow-up due to filamentation

Bam 2 Losses Unstable Bunches

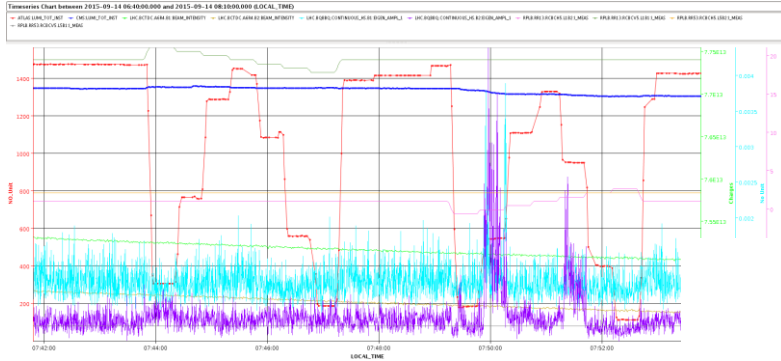

B2 V unstable in Squeeze 1st TRAN of 72 bunches most affected then few individual bunches in other trains

Why? No BB apparent reason, these bunches are like all the central ones in other trains...!

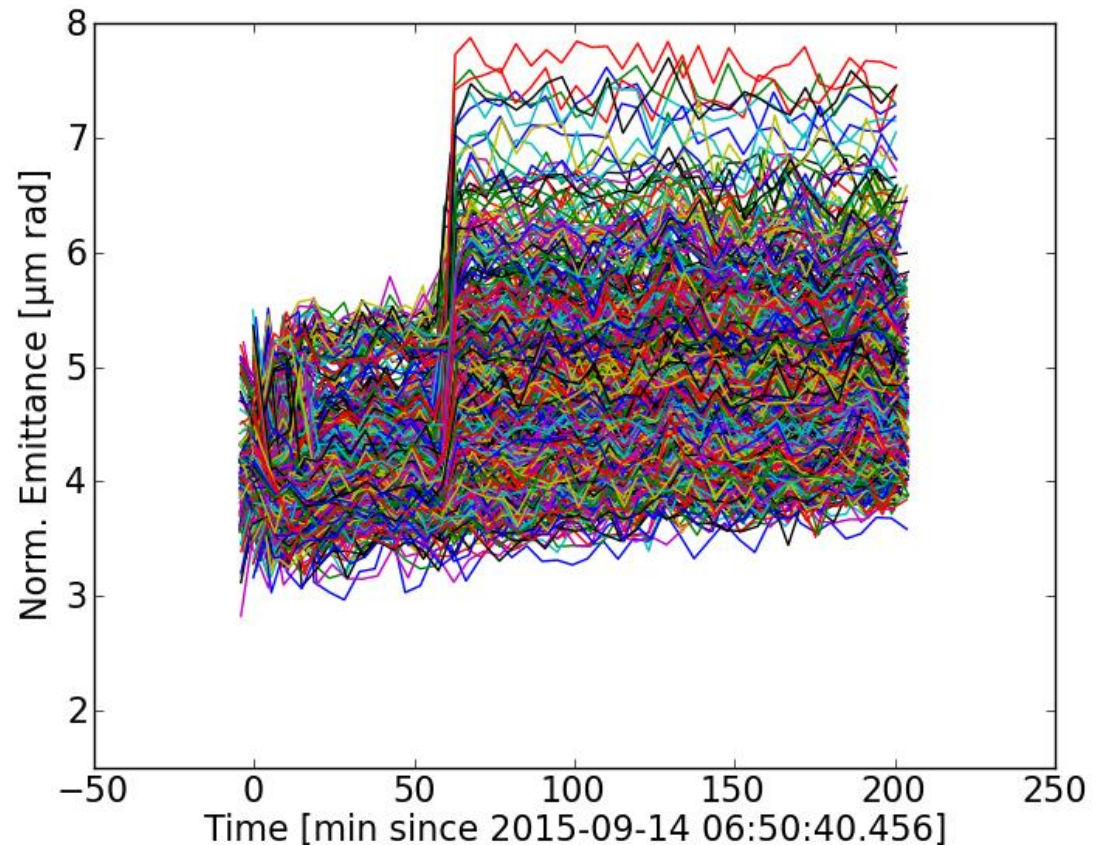

Beam 2 sees BB parameter 0.004 → sees the strong non-linear force of Beam 1 and sees Beam 1 oscillating → Modulated non-linearity scraping away particles since it is already large (emittance reduced) and large losses

Separated beams: instability

Horizontal Plane

Instability develops when
beams are separated by 2σ

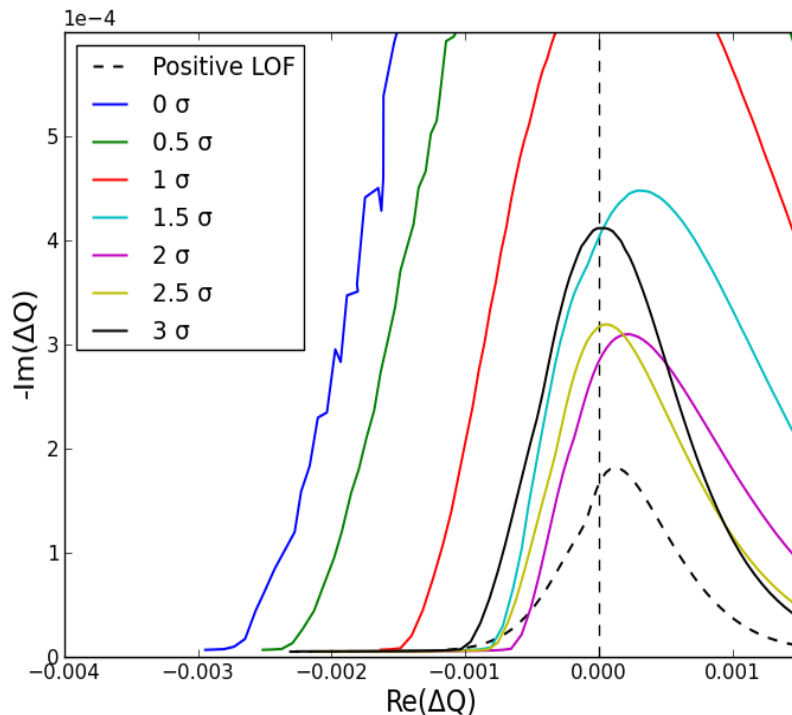

Emittance blow-up of
selective bunches

Only on Horizontal plane

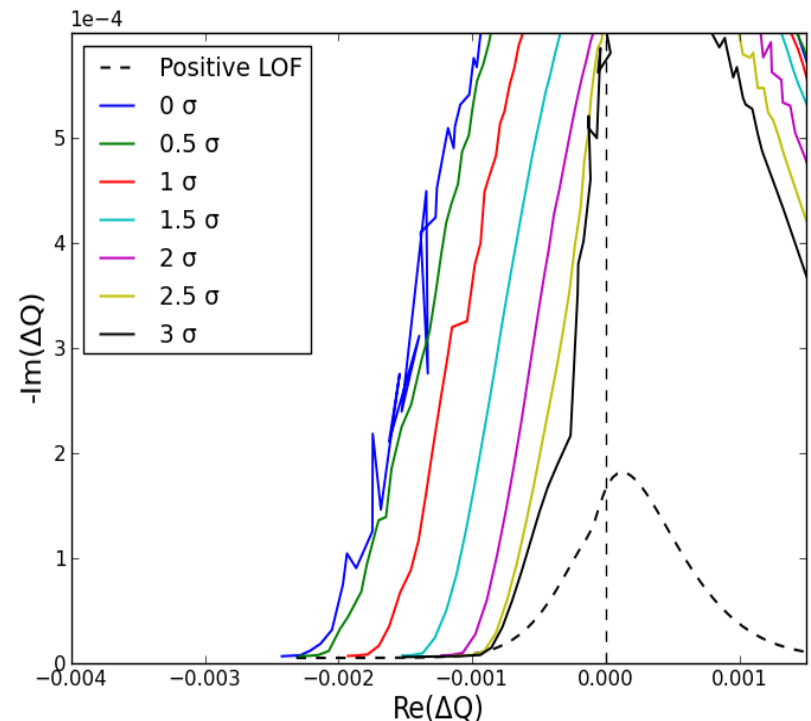

Weaker ADT gain found

Separated beams: instability why at 2σ ?

Horizontal Plane

Vertical Plane

At 2σ separation we have **minimum of stability** even if the other IP is colliding head-on
2 Head-on collisions are needed to guarantee strong stability, at 2σ separation
How are we confident in our understanding of Landau damping?

Beam Transfer Function → Stability Diagram

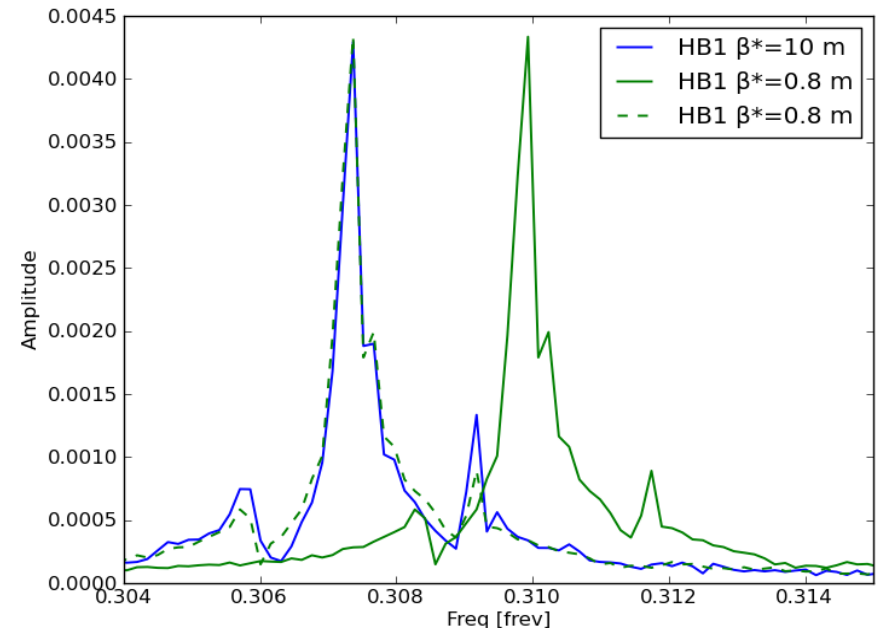

Tune spread and Particle distribution variations

Dispersion Integral

$$SD^{-1} = \frac{-1}{\Delta Q_{x,y}} = \int_0^\infty \int_0^\infty \frac{J_{x,y} \frac{d\Psi_{x,y}(J_x, J_y)}{dJ_{x,y}}}{Q_0 - q_{x,y}(J_x, J_y) - i\epsilon} dJ_x dJ_y$$

Octupole Effects and Chromaticity

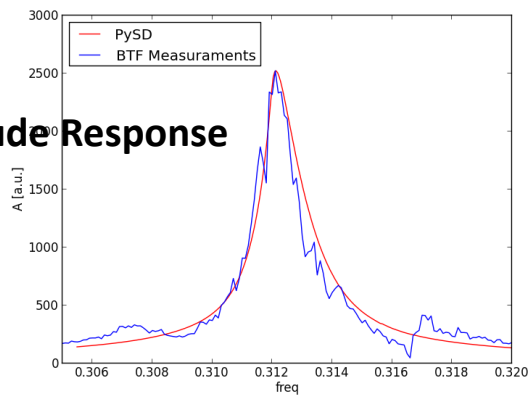

Long Range effects at end of squeeze (14σ)
NO effect!

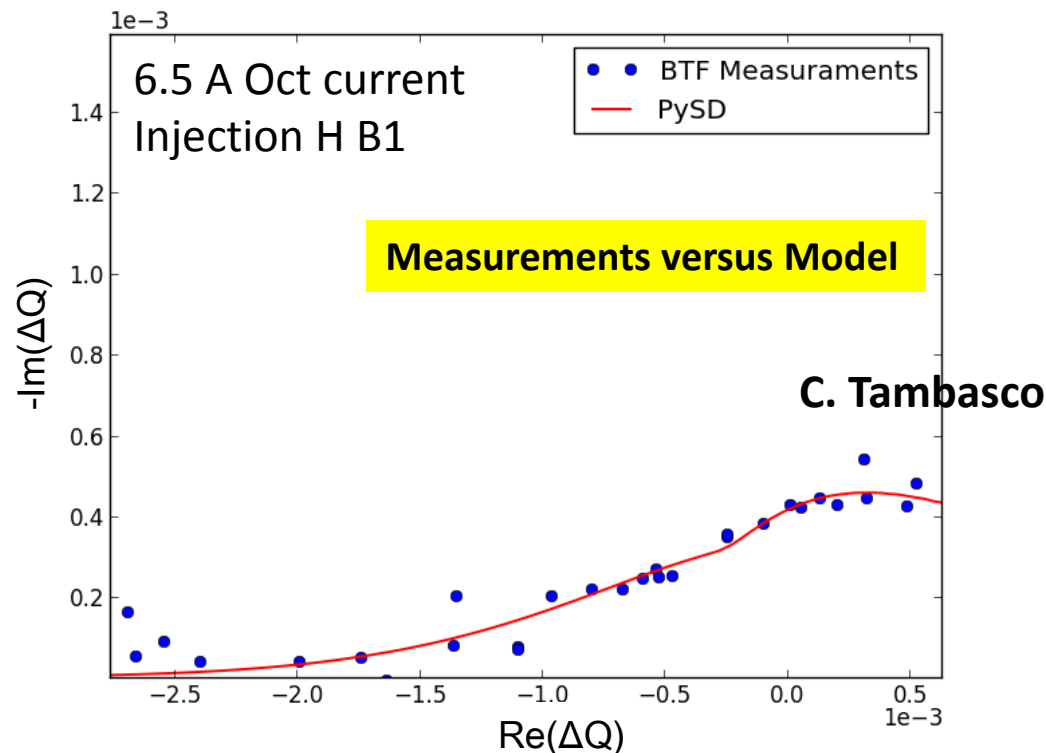

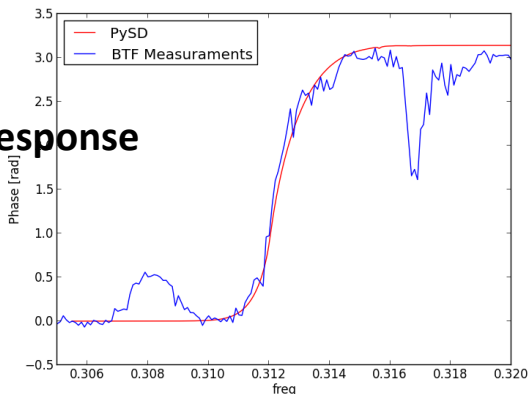

First attempt to reproduce Stability Diagram

- Very challenging already in simple cases, but powerful tool → octupole, chroma scans
- Spread from octupoles and Chromaticity effects still under study
- Transparent to beams!
- **Still need a lot of work to understand (kick amplitude, resolution)**
→ tools in place but need more data in 2016 !

Amplitude Response

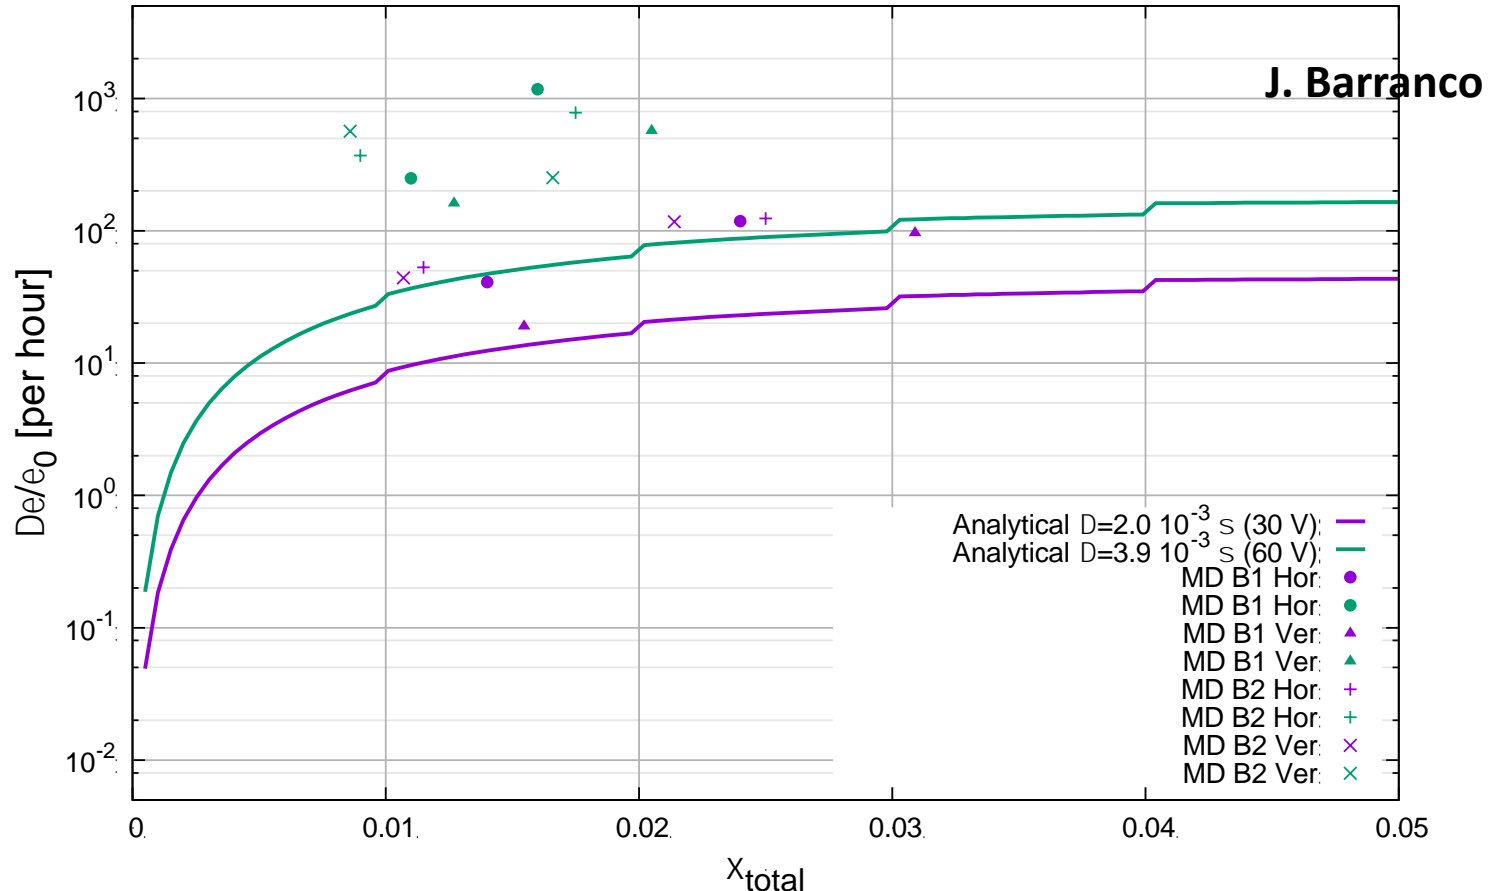

Phase Response

Noise on colliding beams at injection

1st Fill | Damper Gain $g_0=0.1$ (20 turns)

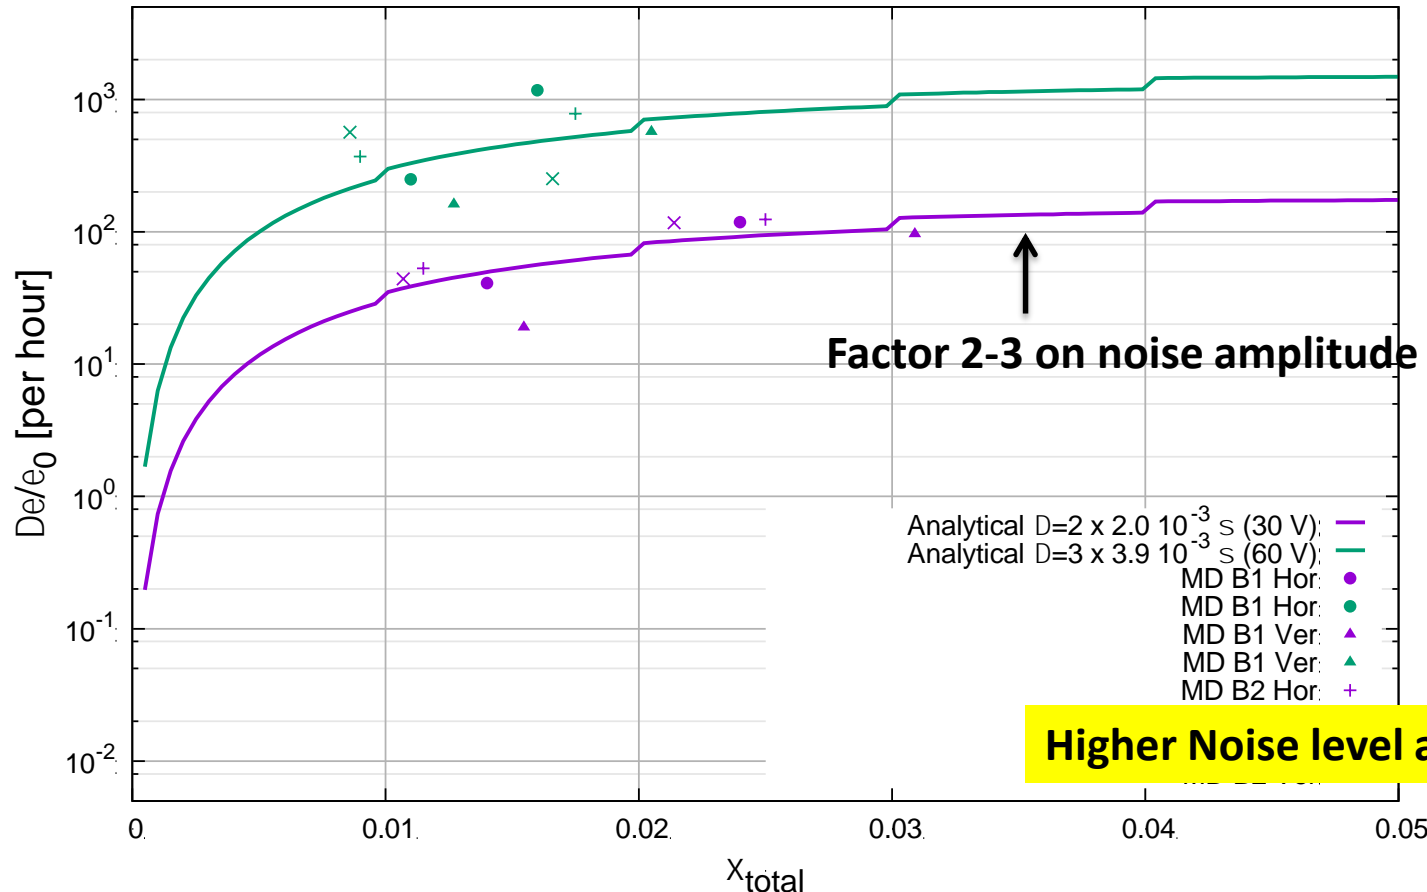

Injection Energy: introduce white noise different amplitudes
Single bunches with different BB parameter in collision
Different white noise amplitude used

Thanks to D. Valuch

Noise on colliding beams at injection

1st Fill | Damper Gain $g_0=0.1$ (20 turns)

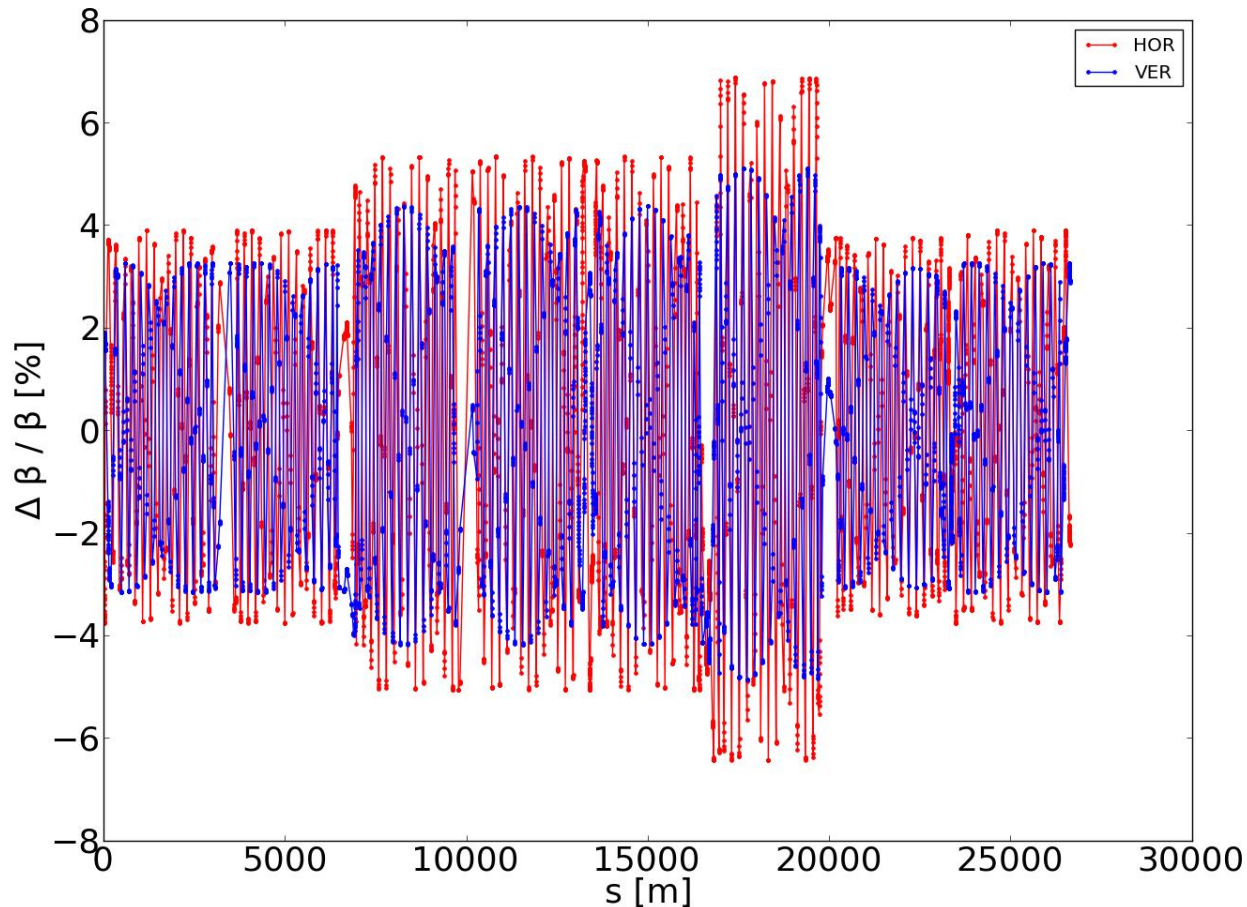

Missing ingredients in the model, beam-beam dependency consistent with expectations!

Very reproducible 3 case MD1!

To be understood to estimate HO limits → Is this the same at 6.5 TeV?

Growth present on non-colliding bunches ...

Beta beating from Beam-beam HO

The beam-beam head-on collisions IP1&5 provokes a beating around the accelerator of maximum 7 % 2015 case (very important for larger beam-beam parameters HLLHC 20%)

Very different for core and tail particles... needs further studies.

Summary

- **2012 luminosity lifetime was strongly affected by beam-beam effects** (together with Oct and Q') → **DA was very close to 4 σ limit** were losses increase and lifetime reductions are observed
- 2015 strategy was to allow for High Chroma and Octupole operation
 - **IP1&5 DA BB+Oct+Q' around 6 σ** (high brightness and nominal beams 290 μ rad)
 - **IP2& IP8 in the shadow** of IP1&5 → larger beam-beam separations (shift-spread 10^{-4})
 - **Identify Limit and Quantify the impact** of crossing angle on beam and lumi lifetimes
→ **Limit @ 4 σ Dynamical Aperture** → 8.4 s separation → **2.6 σ margins**
- 2016 apply same strategy (**50 and 40 cm optics are very similar**)
 - **10 σ beam-beam separation (330-370 mrad)** gives DA above 6 σ (40cm slightly smaller head-on improves)
 - **IP8 will stay identical** as 2015 RUN (500 μ rad external crossing in collisions)
 - **IP2 will need 400 μ rad external xing angle in stable beams** to allow for spectrometer polarity change (At Injection copy and paste of IP8 with proper xing V plane)
 - **If Octupoles and Chromaticity reduced in stable beams** → still room for reduction after quantifying impact on lifetimes and losses
 - Could **non-colliding bunches have reduced intensities?**

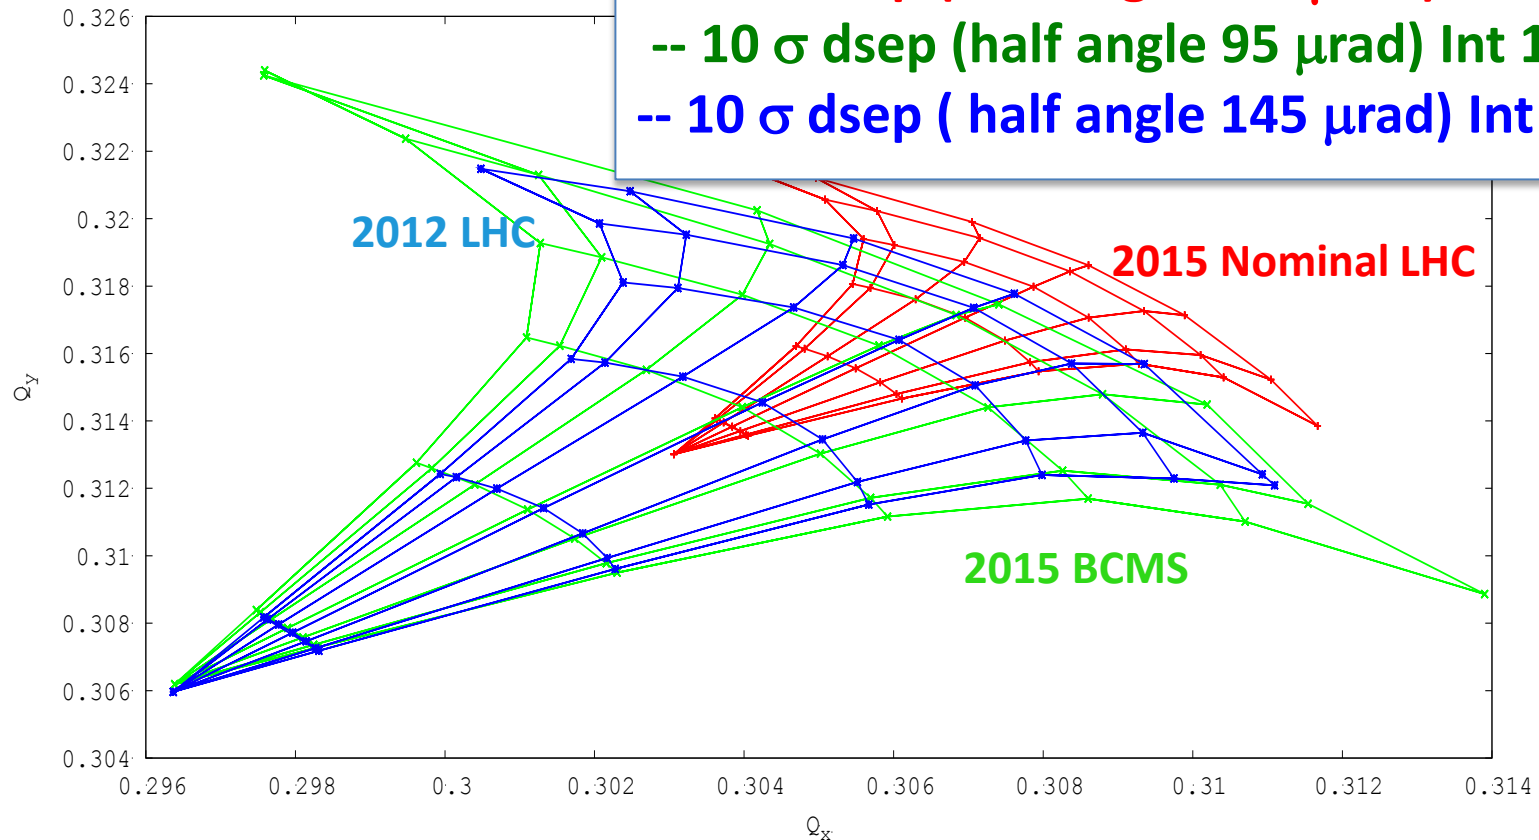

Summary

- **Colliding beams are rock stable**
 - **Weak-strong configuration** leaves strong beam without Landau damping from head-on collisions, colliding companions of unstable bunches will still be sensitive in stable beams
 - **Separated beams at 2σ** we will have **minimum of stability** → possible ADT gain reduction, reduced Octupoles and Chroma might lead to instability (beams should be separated with care!)
- **Beam Transfer Function Measurements with BB: powerful tool :**
 - Promising first results of amplitude response (Octupole and Q' scans)
 - Quantify long range effects (Stability diagrams, resonance excitation etc).

Need more systematic data in 2016 to explore the sensitivity to particle distribution variations and to understand possible use of this device.
- **Noise on colliding beams** had highlighted important missing ingredient at injection energy → needs to verify at top energy to identify head-on limit!
- **Beta beating from beam-beam** is not negligible in stable beams 7%
 - pushing the beam brightness will make it stronger → need to measure
 - On-going studies to understand the implications and the possible correction

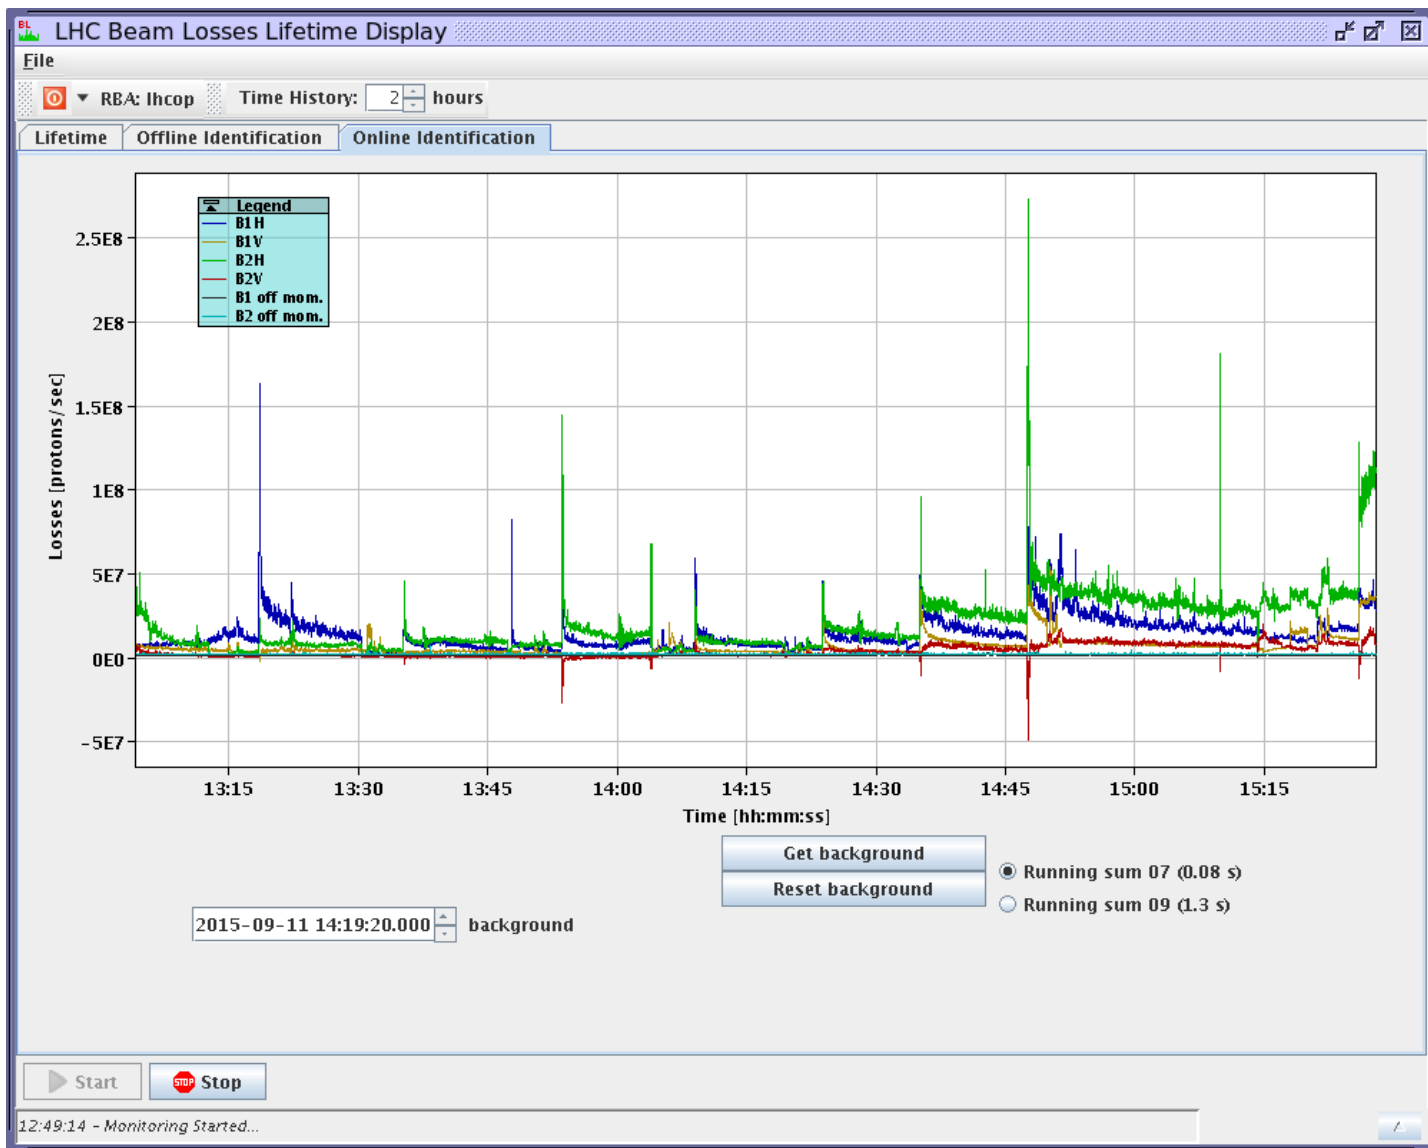

Footprints for 2012 run and 2015 Beams:

Intensities 1.3 e11

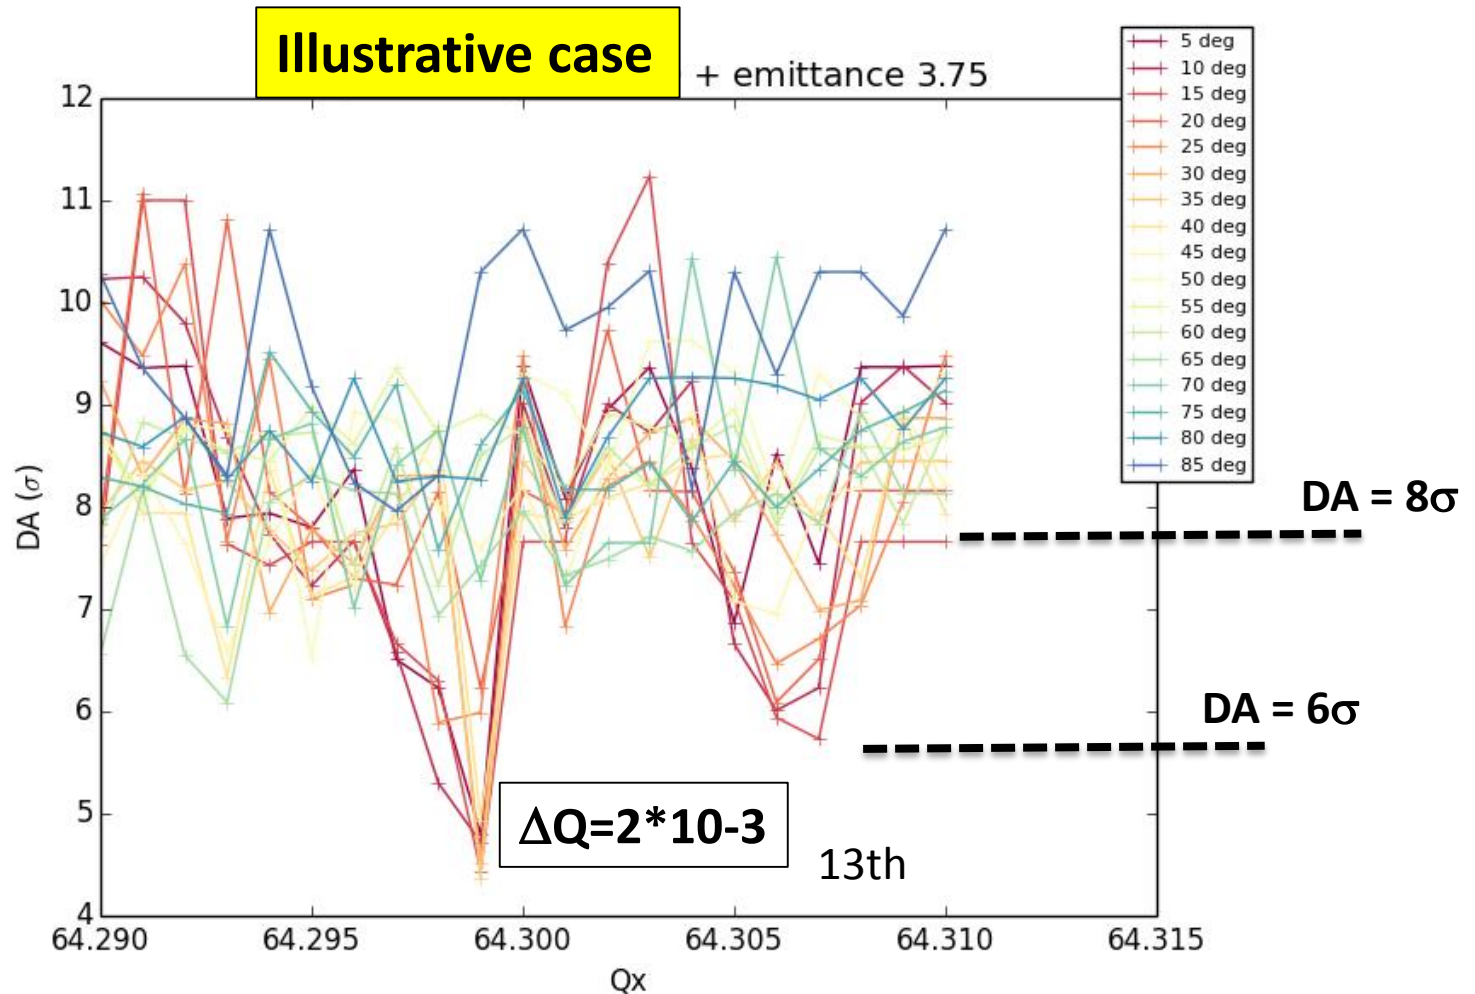

- **BB parameter half of 2012!**
- **Long Range Separation requires changes (10 to 15 σ) depending on the head-on to have similar configurations!**
- **Xing angle for LHC standard valid for BCMS beams**

Losses follows

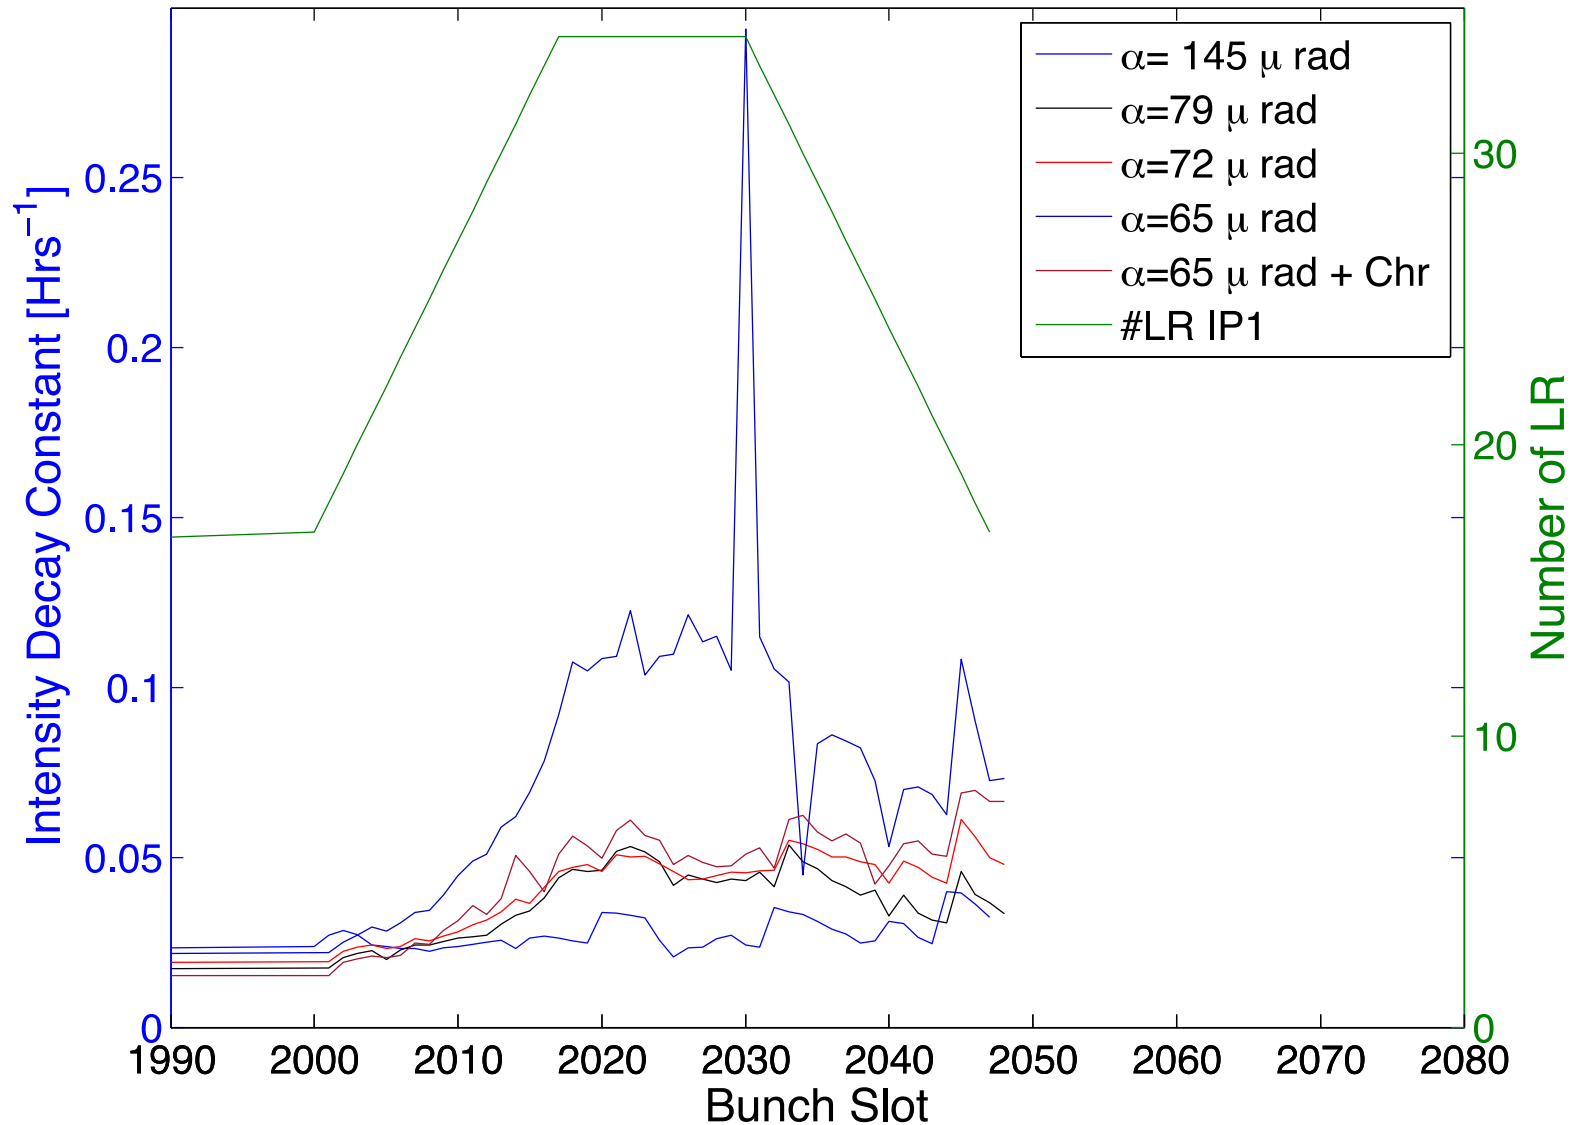

BB dynamics very sensitive to working point

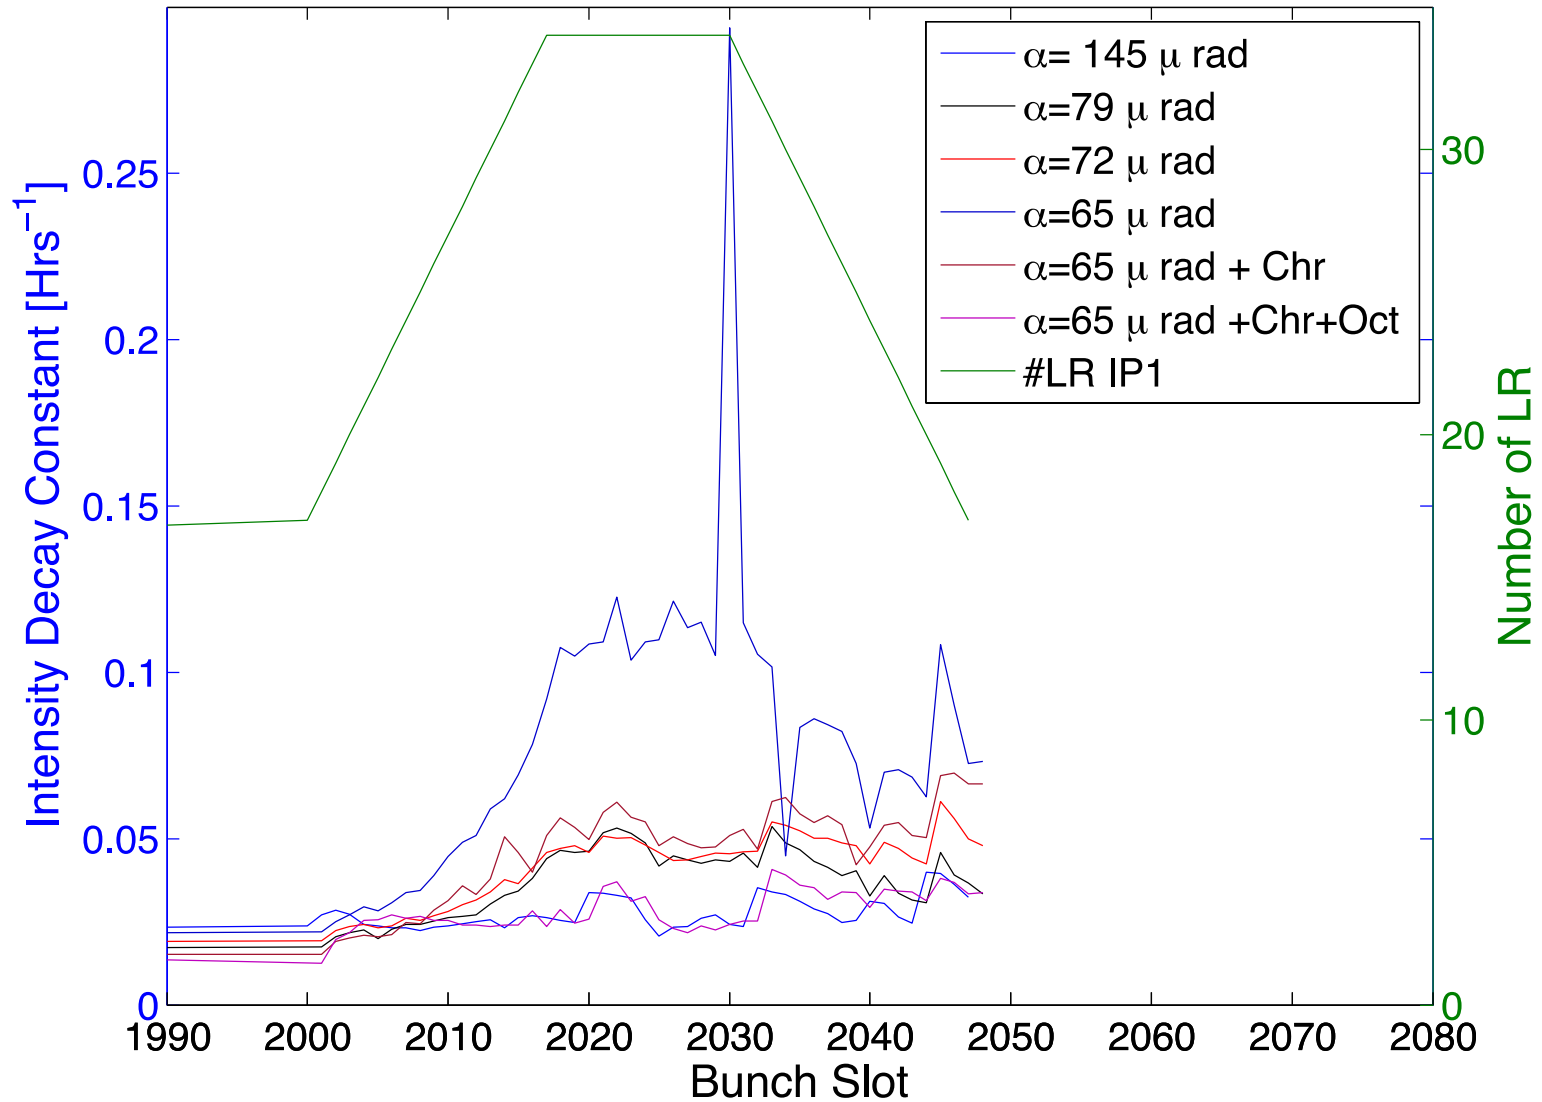

DA can easily drop by 2-3 σ for tune shift of $2 \cdot 10^{-3}$ 13th order resonance \rightarrow Keep IP2 and IP8 tune shift smaller than 10^{-4}

Beam 1 Intensity decay versus bunch

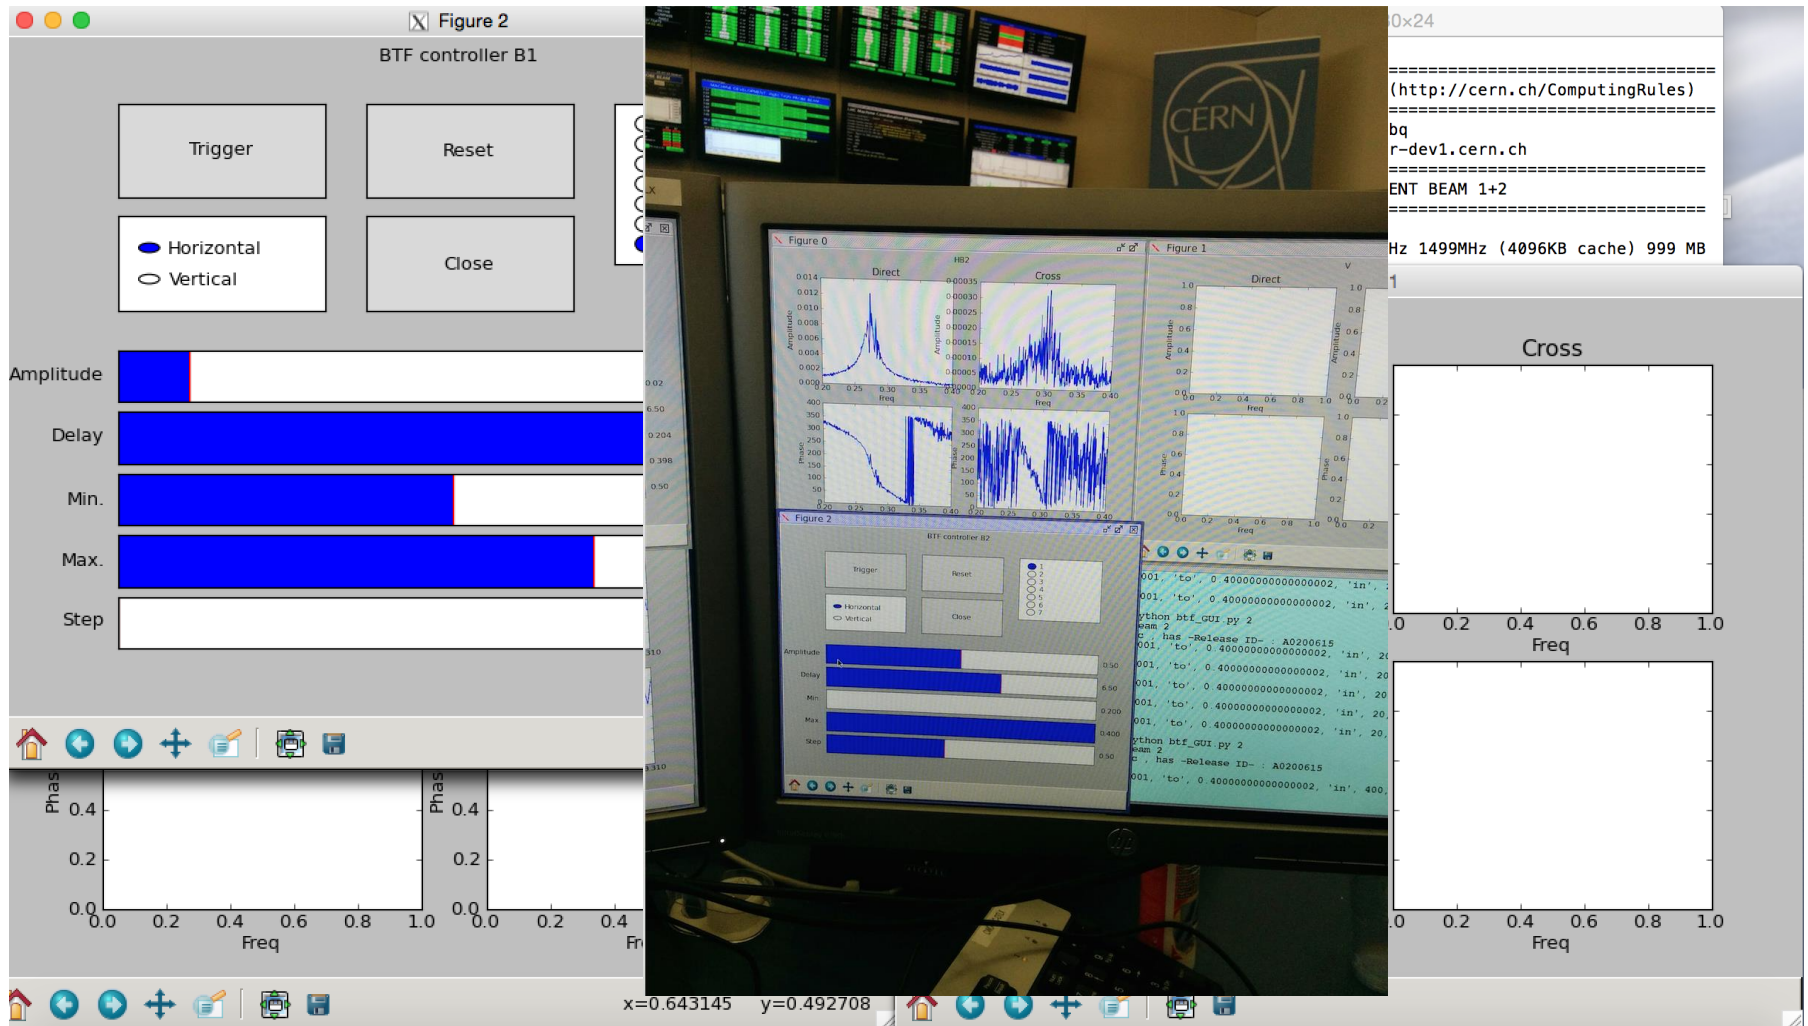

Reducing the crossing angle Beam lifetimes are reduced from 30→8-5 hours
Reducing Chromaticity

Beam 1 Intensity decay versus bunch

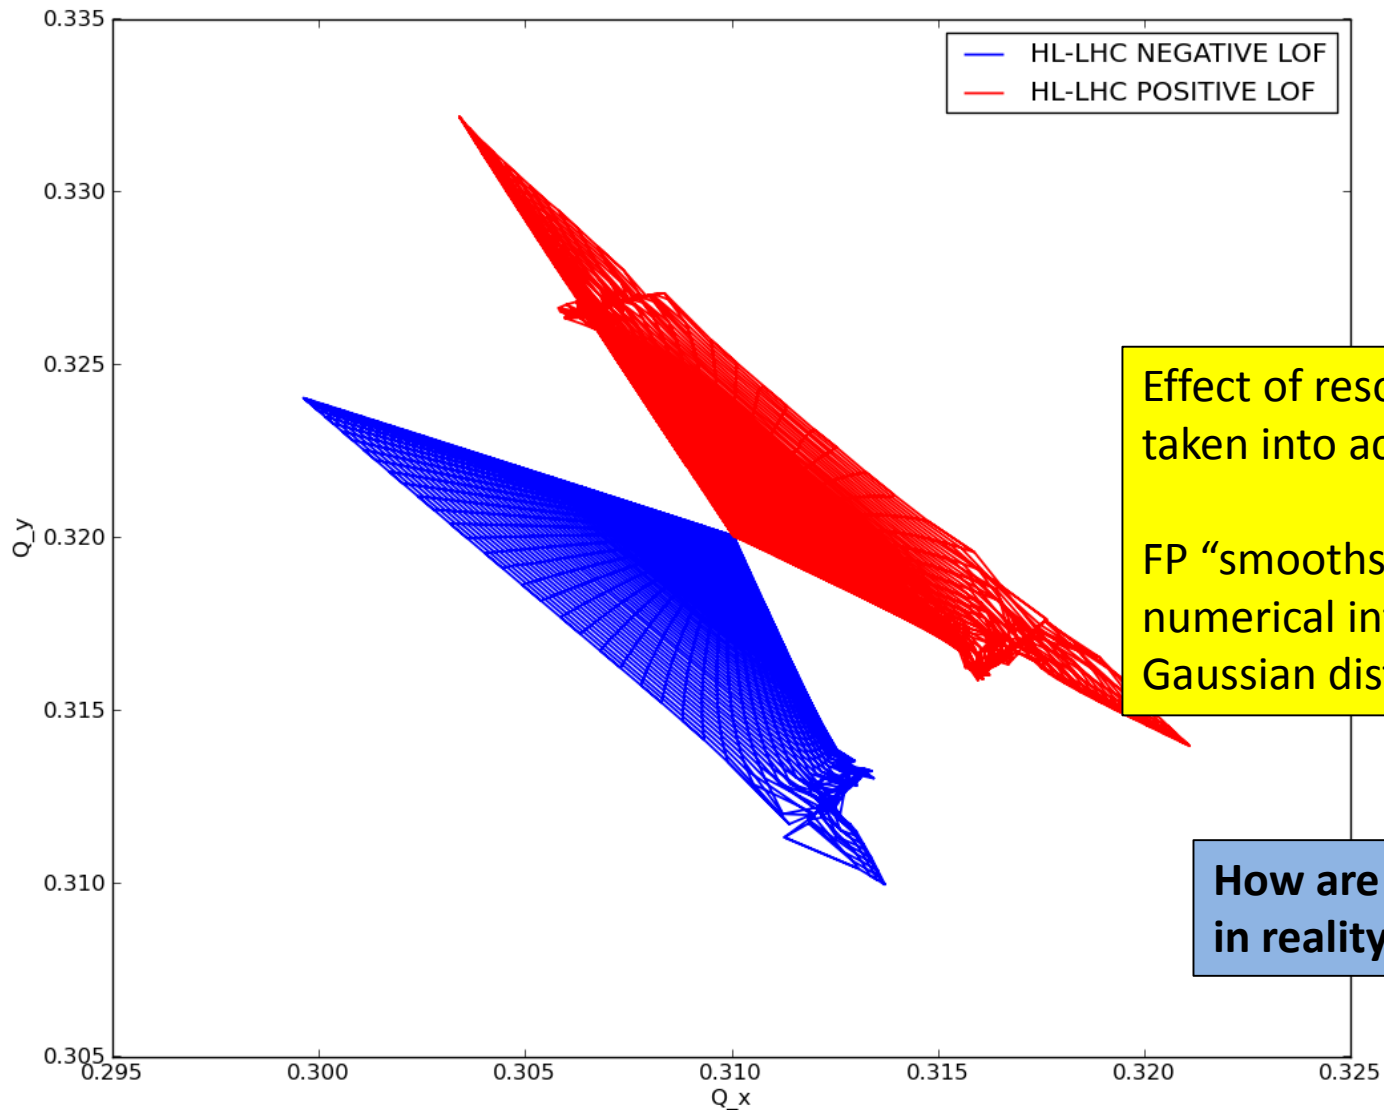

**Reducing $Q'_{15} \rightarrow 2$ units and Landau Octupoles from 476 $\rightarrow 0$ A
Lifetimes improves going back to 30 hours**

BTF GUI in the CCC: simple and expert based... not yet operational!

Modified distribution: Non-Linear Resonances

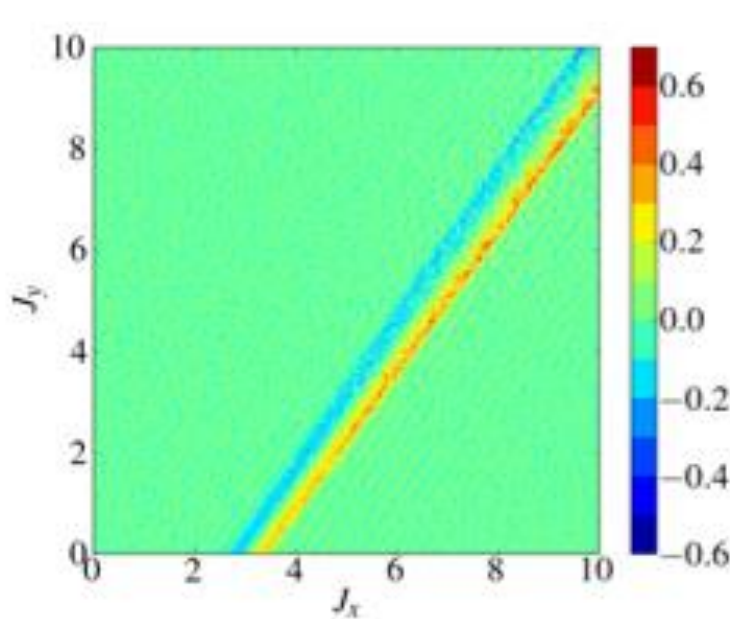

Effect of resonances are not fully taken into account

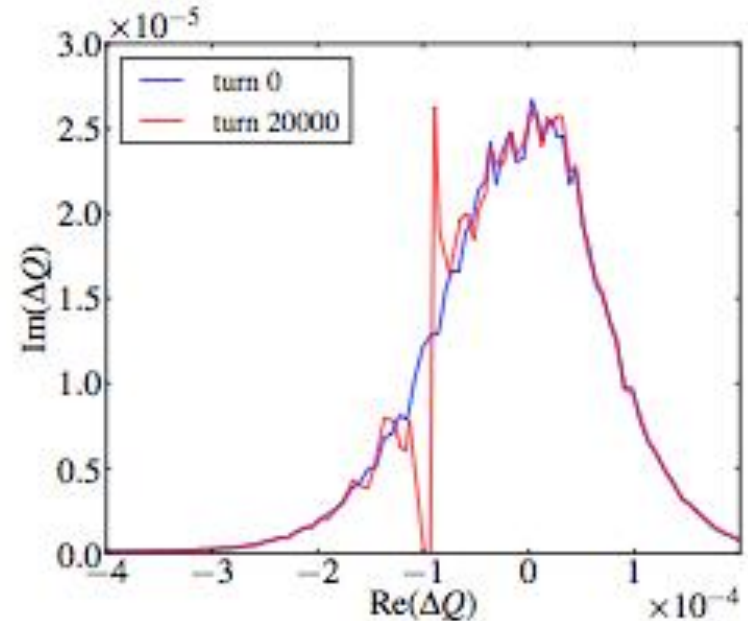

FP “smooths” the resonances and numerical integration assumes Gaussian distributions

How are particles distributed in reality along resonances?

What happens to SD (BTF) if particle distribution modified?

(a) Relative deviation from the initial distribution in action space

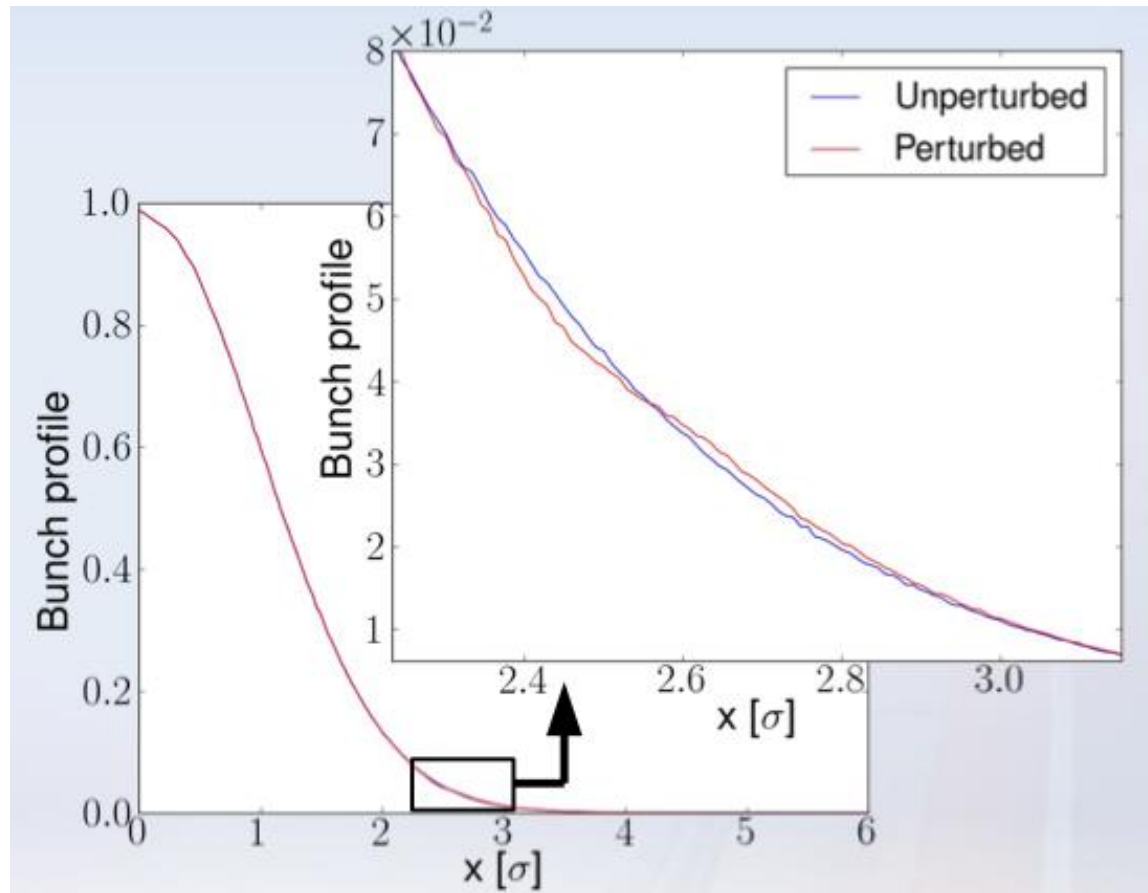

(b) Stability diagram before (blue) and after (red) the distortion of the distribution.

$$SD^{-1} = \frac{-1}{\Delta Q_{x,y}} = \int_0^\infty \int_0^\infty \frac{J_{x,y} \frac{d\Psi_{x,y}(J_x, J_y)}{dJ_{x,y}}}{Q_0 - q_{x,y}(J_x, J_y) - i\epsilon} dJ_x dJ_y$$

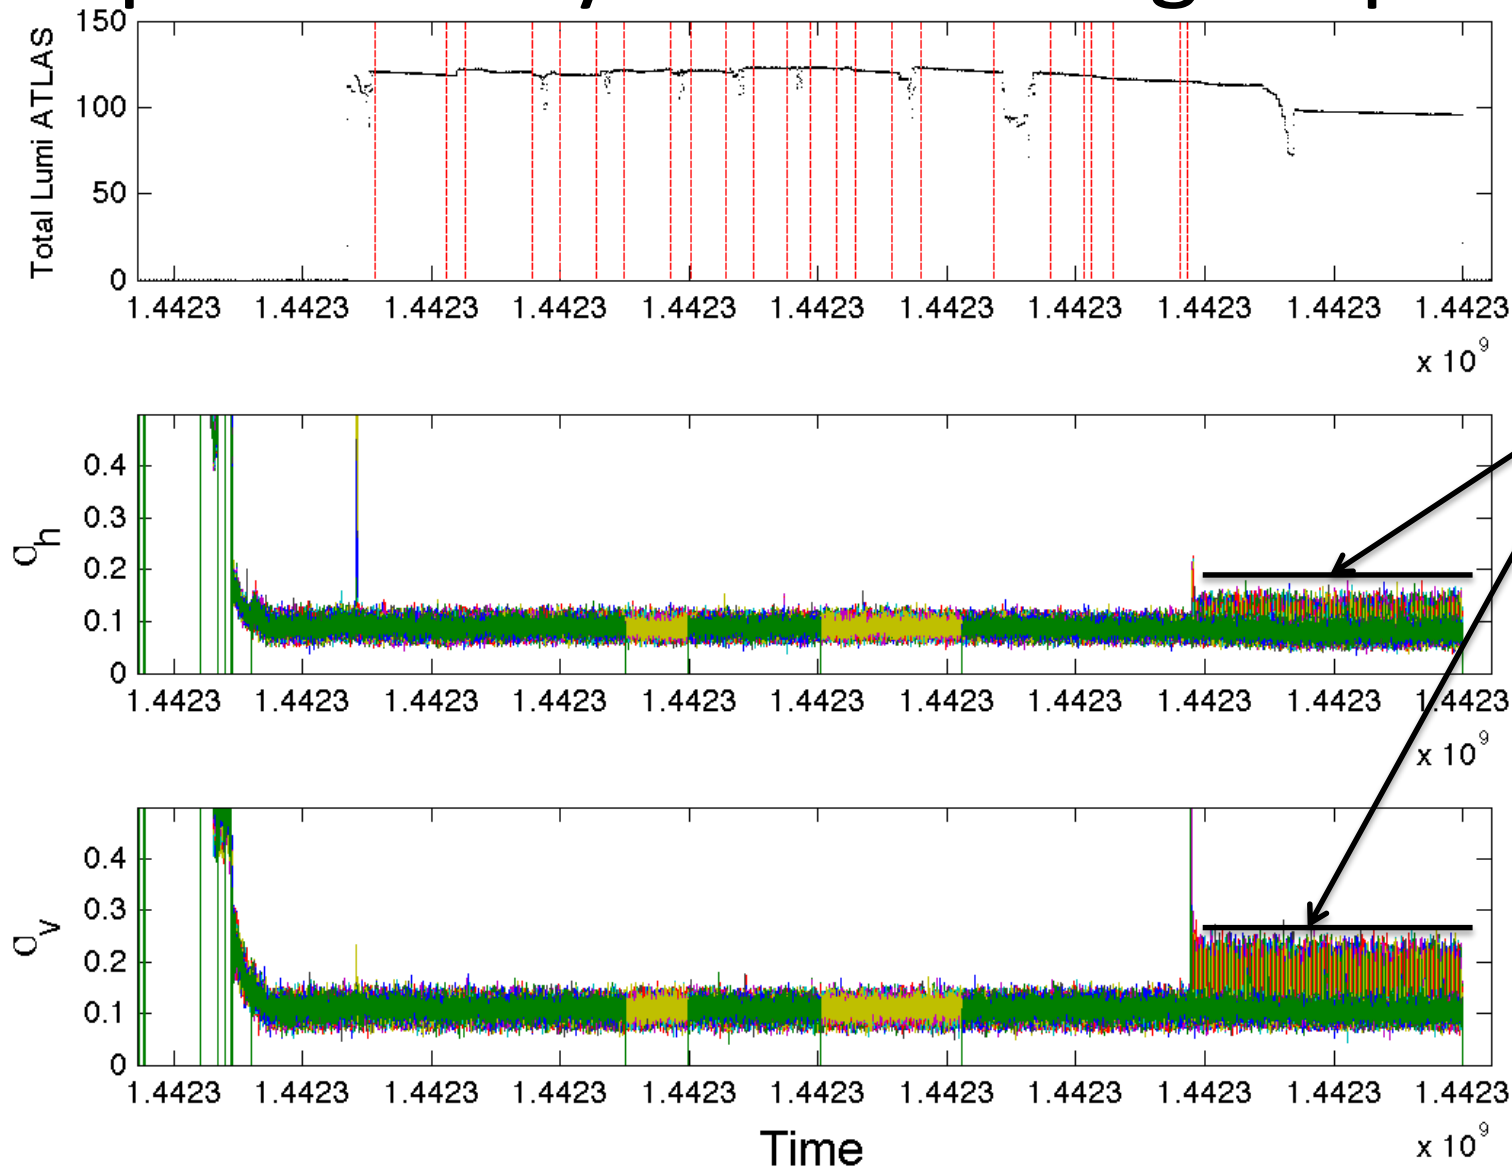

- Colored Noise source \rightarrow Diffusion of resonant particles
- Modification of particle density in action space with time
- **Strong effect on stability diagram at edge of variation (derivative of distribution)**

Modified distribution: Colored Noise

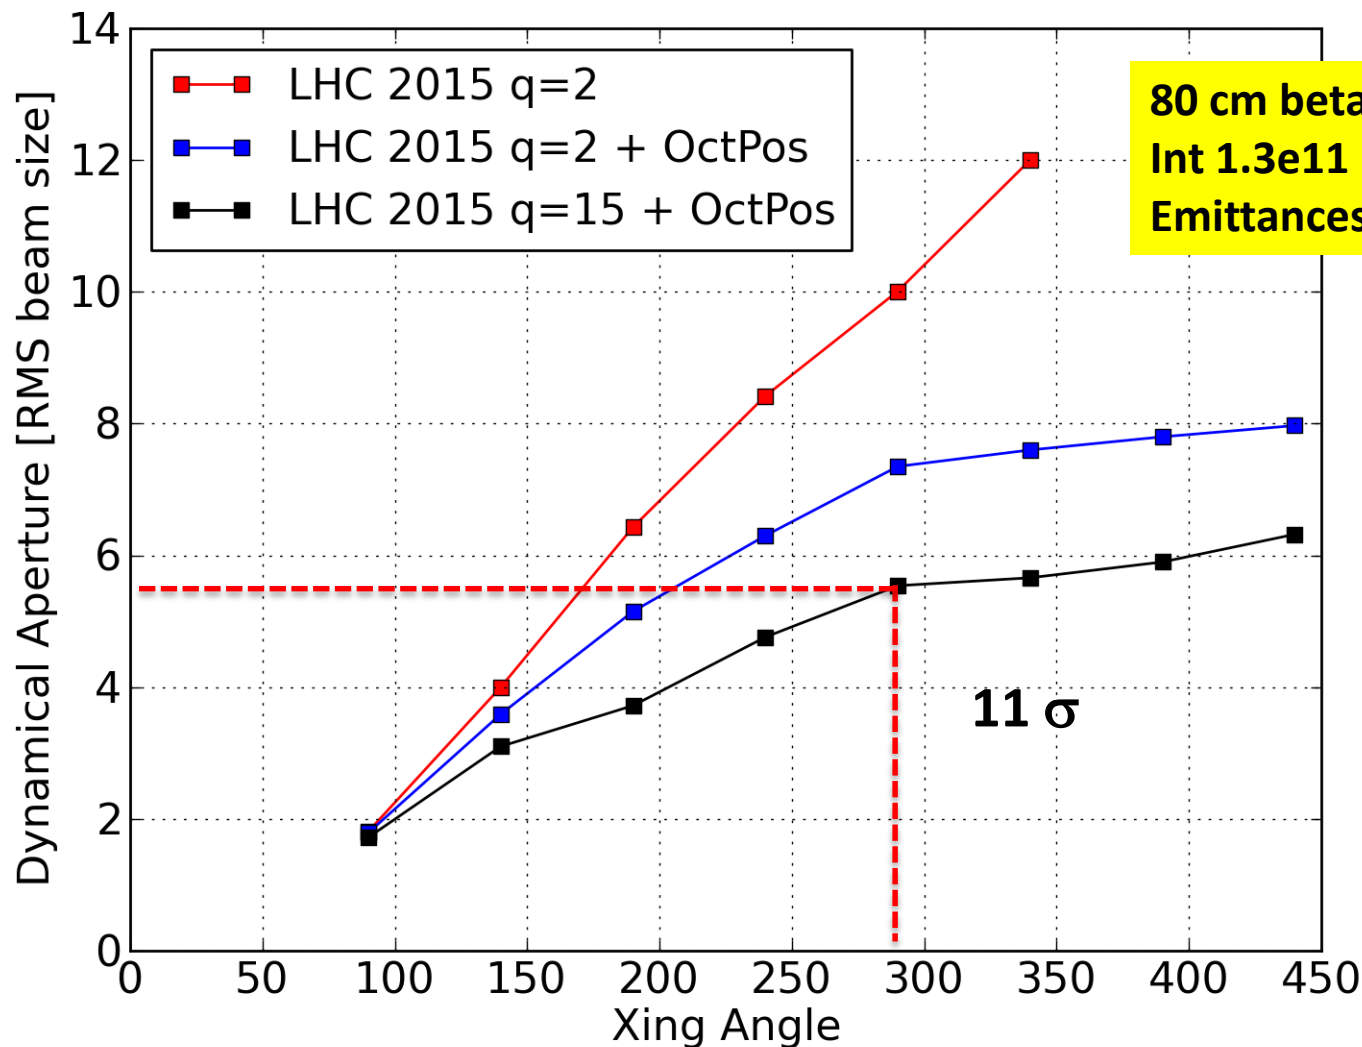

- Effect on particle distribution very small (% level)
 - Profile measurement dominated by core of beam
- Impossible to measure the effect with profile measurement!**

Preliminary emittance plots (only qualitatively correct of sigma planes)

2016 Xing angles IP1&5

2015 Set-up
