for the invaluable support

- **Introduction**
- **Scrubbing at 450 GeV**
- **Intensity ramp-up with 25 ns beams**
 - Beam dynamics observations
 - Heat loads
 - Conditioning observations
- **De-conditioning and re-conditioning observations**
 - Effect of Technical Stops and Special Runs
- **Experience with exotic bunch patterns**
 - Doublets
 - 8b+4e
- **First lessons to retain and possible strategy for 2016**

- One of the **main goals** of the 2015 run was to explore operation at **6.5 TeV** with **25 ns** beams
- Expected **challenges from e-cloud effects** (as anticipated from 25 ns pilot run in 2012)
 - Plenty of time allocated for **scrubbing**
- Decided to operate with **~nominal bunch parameters** (injecting 1.1×10^{11} ppb in 2.5 μm)

(*) Limited to ~450b. by radiation induced faults in QPS electronic boards (fixed during TS2)

- Introduction
- **Scrubbing at 450 GeV**
- Intensity ramp-up with 25 ns beams
 - Beam dynamics observations
 - Heat loads
 - Conditioning observations
- De-conditioning and re-conditioning observations
 - Effect of Technical Stops and Special Runs
- Experience with exotic bunch patterns
 - Doublets
 - 8b+4e
- First lessons to retain and possible strategy for 2016

- **After LS1 the SEY was practically reset** w.r.t what was observed at the beginning of Run 1
 - e-cloud induced instabilities were observed even with 50 ns
- During **(1+2) weeks** of scrubbing at 450 GeV,
 - Regularly filling the machine with **up to ~2500b. with 25 ns spacing** at 450 GeV
- Main **limitations to the scrubbing efficiency**:
 - **e-cloud instabilities** (dump from BLM or interlocked BPM dumps), evidently getting better with scrubbing
 - **Transients on beam screen temperatures** → long waiting time between injections (should be better now with the new CM rules)
 - Vacuum spikes at the **TDI8** limiting the intensity for beam 2 (see talk by A. Lechner)
 - Pressure rise in the **MKIs** (required close follow-up by TE-ABT and TE-VSC team, interlock changes)

Scrubbing for 25 ns operation

Follow-up and **optimization** of the process heavily based on lost of **non-standard diagnostics** (heatload, RF stable phases, data from ADT pickups)

→ **many thanks** to the different teams for the **great preparation work!**

SEY was reconstructed comparing **heat load** and **RF stable phase** measurements against **PyECLOUD** simulations

→ **Observed reduction of the SEY** confirmed by steadily **improving beam quality**

Intensity ramp-up with 25 ns beams: beam dynamics

- Scrubbing Run provided **sufficient mitigation against beam degradation** at 450 GeV but **full suppression of the e-cloud was not achieved**
 - During the physics intensity ramp-up we had to learn how to **run the machine in the presence of the e-cloud**
- **Tricky to ensure beam stability at 450 GeV**: need for high chromaticity and octupoles settings and for full transverse damper performance (see talk by L. Carver)
- Slightly **changed working point at injection** to better accommodate large tune footprint from Q' , octupoles and e-cloud

Intensity ramp-up with 25 ns beams: heat loads

- In the first stages, even with relatively low number of bunches, strong **transients of the beam screen temperatures** were observed, leading to loss of cryo-conditions :
 - Intensity ramp-up performed in “**mini-steps**” for fine tuning of cryo-regulations
 - During the first stages, **injection speed often decreased** to control beam screen temperatures
 - Limitation from transients strongly **mitigated over the year by** (see talk by K. Brodzinsky):
 - ➔ **Modified Cryo Maintain rules** to allow for larger temperature excursion
 - ➔ Improvement on **cryogenic feed-forward** control

Intensity ramp-up with 25 ns beams: heat loads

- Around $\sim 1450\text{b.}$ (1.5×10^{14} p) we started approaching the **limit of the available cooling capacity** on the arc beams screens. Additional margin gained by:
 - Increased **longitudinal emittance blow-up** on the ramp
 - **optimized filling scheme** to gain additional margin
- By the end of the proton run **reached 2244b.** (in trains of 36 b.) with 1.2×10^{11} ppb

Scrubbing accumulated during the physics run

- Heat load per bunch **significantly decreased during the physics run**
→ **Reference fill** performed at the end of the run in order to disentangle contributions from scrubbing and beam tuning

Scrubbing accumulated during the physics run

At the end of the p-p run we repeated an early fill of the intensity ramp-up

- **Very similar beam conditions** (filling pattern, bunch intensity, bunch length)
- After 2 months, significant **reduction visible in all arcs** (30% to 60% depending on the sector)

14 September – Average arc half cells

4 November – Average arc half cells

Scrubbing accumulated during the physics run

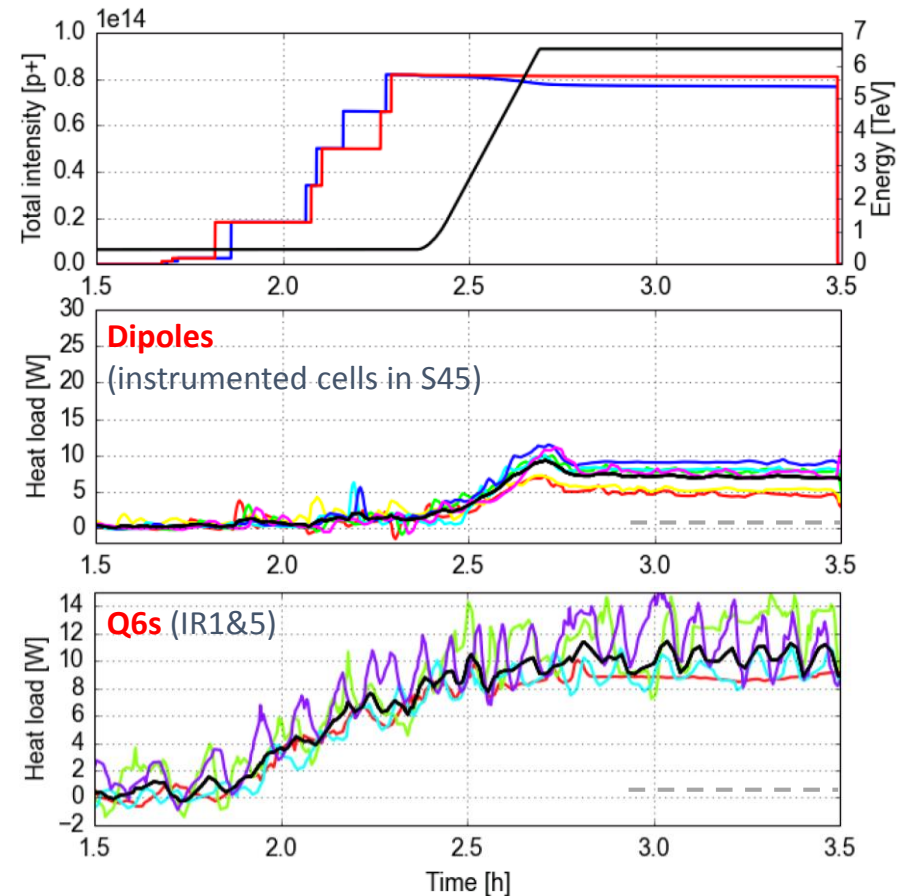

At the end of the p-p run we repeated an early fill of the intensity ramp-up

- **Very similar beam conditions** (filling pattern, bunch intensity, bunch length)
- After 2 months, significant **reduction visible in all arcs** (30% to 60% depending on the sector)
- Reduction observed **mainly in dipole magnets** (higher SEY threshold compared to quads)

Scrubbing accumulated during the physics run

At the end of the p-p run we repeated an early fill of the intensity ramp-up

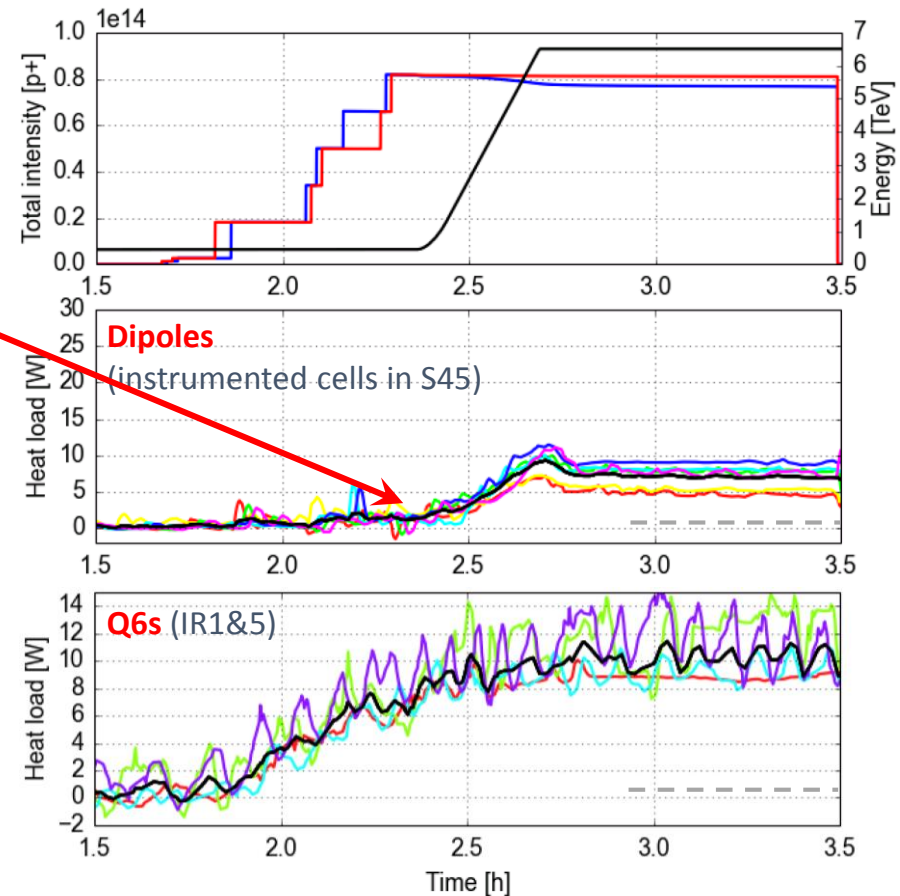

- **Very similar beam conditions** (filling pattern, bunch intensity, bunch length)
- After 2 months, significant **reduction visible in all arcs** (30% to 60% depending on the sector)
- **magnets** (higher SEY threshold compared to quads)

Practically **no measurable heat load in the dipoles at 450 GeV** (at least in S45)

→ **SEY** should be below **1.4**

4 November

— Average

-- Impedance+synch. rad

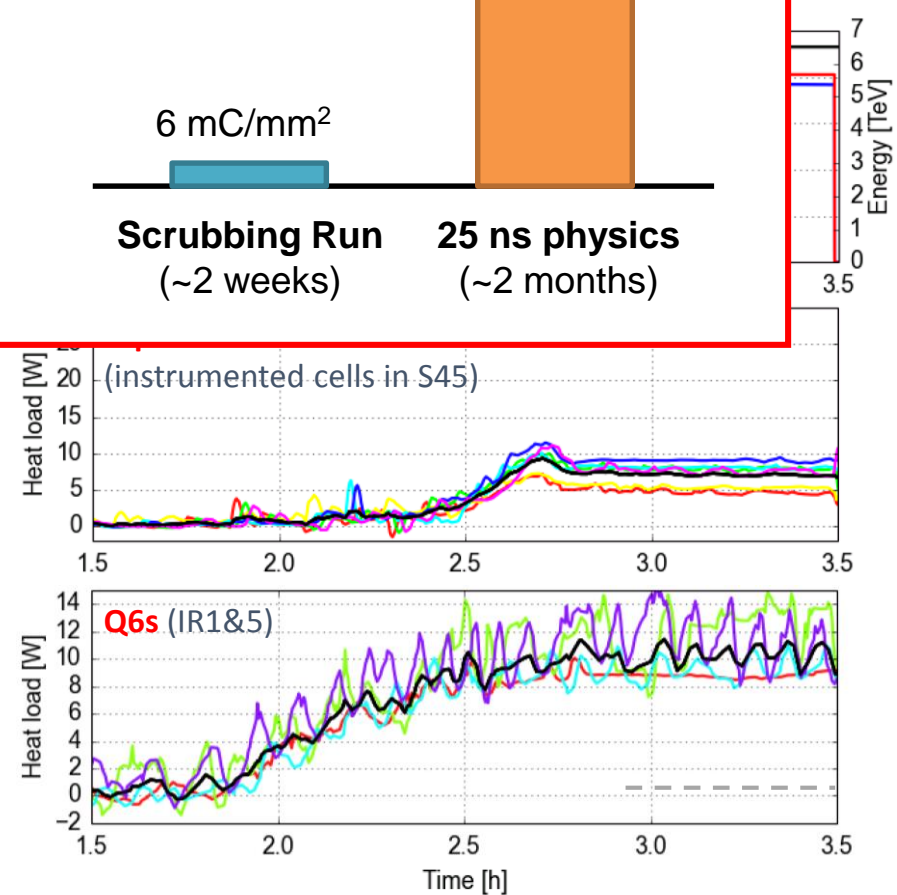

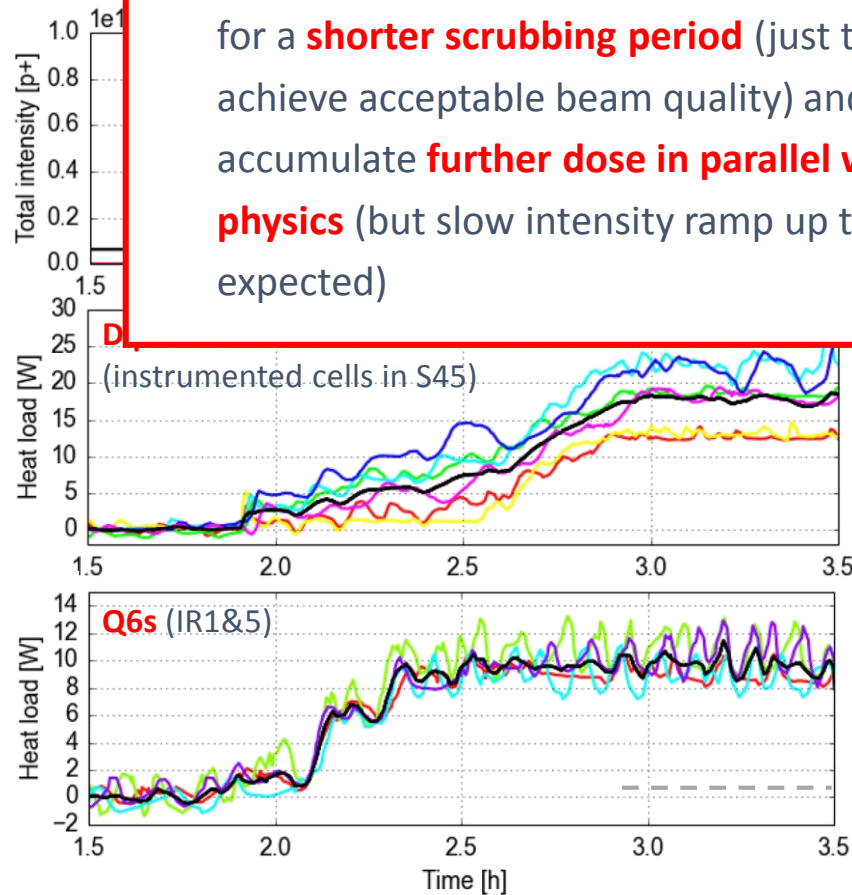

Scrubbing accumulated during the physics run

Electron dose needed to achieve factor two reduction on the heat load at flat top is **very large**:

- Difficult to accumulate in a reasonable time with dedicated scrubbing run
- In the future (e.g. after LS2) we might go for a **shorter scrubbing period** (just to achieve acceptable beam quality) and accumulate **further dose in parallel with physics** (but slow intensity ramp up to be expected)

Accumulated e^- dose

— Average
-- Impedance+synch. rad

Situation at the end of the p-p run

Achieved in 2015: 2244b. in trains of 36b.

Nominal: 2748b. in trains of 72b.

22% more bunches but **40% less gaps**
→ expected **~50% more heat load**

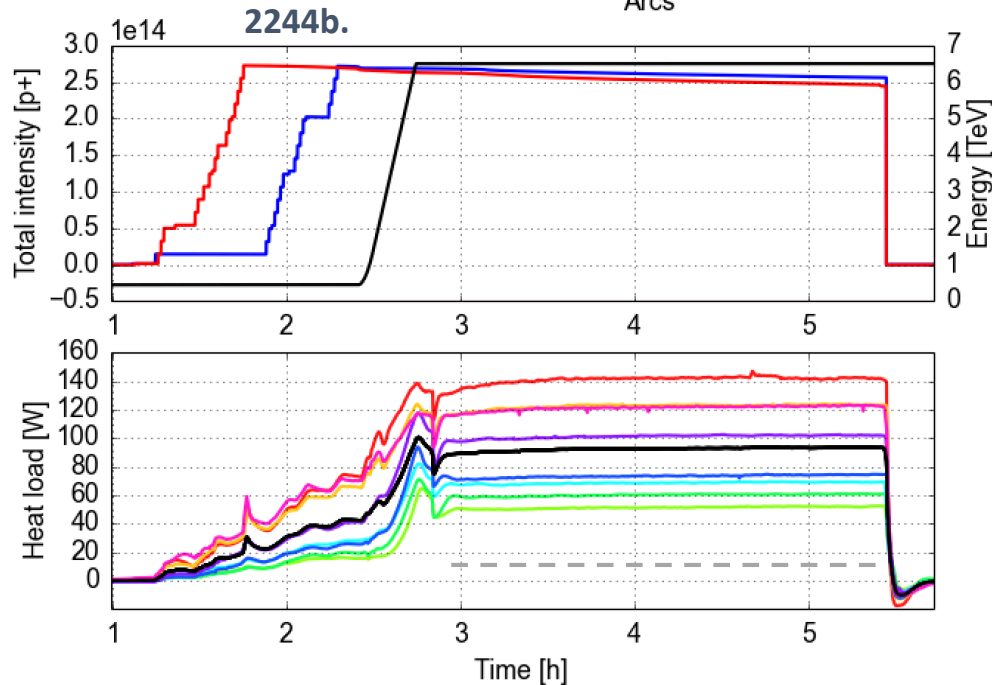

Situation at the end of the p-p run

Achieved in 2015: 2244b. in trains of 36b.

Factor 3 spread among heat loads in different sectors! - reason not clear

- Sectors **81, 12 and 23** close to the **limit** with this filling scheme
- Sectors 34, 45, 56, 67 have already enough margin to accommodate the nominal beam

Situation at the end of the p-p run

Achieved in 2015: 20000 bunches

On the **difference among sectors:**

- It is **not a measurement artefact** (test cells calibrated with heaters)
- In **2012** distribution was different (S45 and S56 were the worse at the time)
- It is there with **only beam 1** (and gives half the value)
- It was observed also with **50 ns**, then disappeared with scrubbing
- It was observed with **doublets** (see later)
- Difference is **increasing with time** (good sectors condition faster)
- There is **no dependence on the radial position** of the beam (tested +/- 0.2 mm)
- **Thermal cycle** of the beam screen has **no effect** on the heat load
- High heat load sectors seem to have **larger integrated BLM signals**

Doublets

Similarly to scrubbing with 25 ns beams to ensure ecloud-free with 50 ns beams, the **doublet** would **boost scrubbing for 25 ns beams**

Similarly to scrubbing with 25 ns beams to ensure ecloud-free with 50 ns beams, the **doublet** would **boost scrubbing for 25 ns beams**

Preparation work done in 2015:

- Careful **setup in the injectors** → doublets available for the LHC with **$\sim 1.6 \times 10^{11}$ p/doublet**
- First tests with doublets in the LHC** allowed to gain experience on the **behavior of the different LHC systems** (instrumentation, RF, damper, MP) with this bunch pattern
- Interlocked BPMs** (expected to give false readings) were characterized with doublets
→ Interlock windows adapted in order to allow reliable operation

Doublets: instabilities and beam degradation

With doublets, **fast e-cloud induced instabilities** were observed, difficult to control even with high Q' and octupole settings and ADT ON

→ **strong emittance blow-up** and particle **losses**

B2 - Vertical

- Trains **up to 48 doublets could be injected** in the LHC but, due to the instabilities, it was possible to **accumulate only trains of 24 doublets** (up to ~250 doublets in total)
- Despite the strong beam degradation, the **e-cloud enhancement could be observed** on the arc heat load
- But **impossible to inject enough beam** and keep sufficient beam quality **for efficient scrubbing** with doublets

Standard 25 ns beam

"Doublet" beam

- As long as in physics we are **running at the cryogenics limit** (with strong load in the dipoles) by definition there is **no way to increase the scrubbing efficiency**
- On the other hand, when we will have lowered significantly the SEY in the dipoles, doublets **could become interesting** to **bring the SEY below the threshold for 25 ns**
- To achieve a good efficiency with doublets **we need a better control on e-cloud instabilities** and to achieve acceptable beam lifetimes → more bunches in longer trains
- For this purpose:
 - Doublet should be tested **after having accumulated enough scrubbing** with nominal beam (i.e. not at the beginning of the run)
 - Operate with **high Q' to stabilize** and **lower tunes to preserve lifetime**
 - Optimize **ADT configuration** for doublet intensity and working point

- Filling pattern designed to **suppress the e-cloud build-up** (lower thresholds expected from simulations, and verified in SPS MD) → **confirmed experimentally in the LHC** in 2015

Up to ~1850b. in the LHC

Standard 25 ns beam

“8b+4e” beam

— Average
-- Impedance+synch. rad

- Filling pattern designed to **suppress the e-cloud build-up** (lower thresholds expected from simulations, and verified in SPS MD) → **confirmed experimentally in the LHC** in 2015

Standard 25 ns beam

"8b+4e" beam

- Introduction
- Scrubbing at 450 GeV
- Intensity ramp-up with 25 ns beams
 - Beam dynamics observations
 - Heat loads
 - Conditioning observations
- De-conditioning and re-conditioning observations
 - Effect of Technical Stops and Special Runs
- Experience with exotic bunch patterns
 - Doublets
 - 8b+4e
- First lessons to retain and possible strategy for 2016

- **Scrubbing** at 450 GeV allows to **mitigate e-cloud instabilities** and **beam degradation** occurring at low energy
- After this stage, relying on ADT, and high Q' and octupoles, it is **possible to preserve good beam quality from injection to collision** in spite of the e-cloud still present in the machine as witnessed by the heat load in the arcs
- **Parasitic scrubbing** accumulated during the physics run has **lowered the heat load** in the dipoles by roughly a factor two (in two months)
 - The **doses needed** to see an evolution at this stage are **very large**, practically incompatible with a dedicated scrubbing run
 - Possible **recipe for the future**: relatively **short scrubbing at injection** to get the beam under control, then accumulate **further dose in parallel with physics** (but slower intensity ramp up)

- Arcs will be kept under vacuum → **scrubbing should be at least partially preserved** during the YETS
- Scrubbing **requirements for 2016**:
 - **4 days scrubbing run** should be reasonable to recover high intensities at 450 GeV
 - A few **“refresh” scrubbing fills during first 1-2 weeks of intensity ramp up** in physics (to avoid problems with deconditioning)
 - Accumulate **further scrubbing in physics**:
 - **“aggressive” filling scheme**, with up to **288b. per injection**, should be used until we hit again limitations from cryo
 - **Doublet test** to be performed when **SEY is sufficiently low** (e.g. after recovering the 2015 situation) to check whether good beam quality can be preserved
 - In case of positive outcome, **first scrubbing stores with doublets**

Thanks for your attention!
