subversioned system configuration

Wednesday, 5 July 2006 11:00 (30 minutes)

Holger Krekel presents “vadm”, an open-source tool enabling full non-intrusive versioning of unix system configuration files and directories. Multiple administrators can collaborate and communicate over the setup of one machine. Under the hood, vadm uses subversion and the “py lib” and is easy to learn if you know how to use the “svn” command line already. The talk will also present future directions like supporting remote management of a cluster of machines.
