

Rasmus Ischebeck

Diagnostics for FELs and ERLs

CERN Accelerator School: Free Electron Lasers and Energy Recovery Linacs
2016-06-08

Usage of Diagnostics: Measurement and Optimization of Beam Parameters

- Optimization of the emittance from a photocathode gun
- Figure of merit: emittance measured on screen
- Optimization of magnetic fields in the gun, and of RF parameters

Rasmus Ischebeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs

Simona Bettoni, PSI 2

Measure and optimize beam parameters
 > Optimization of one or several parameters, summarized in a figure of merit
 > Manual or automatic optimization possible

Usage of Diagnostics: Find Errors

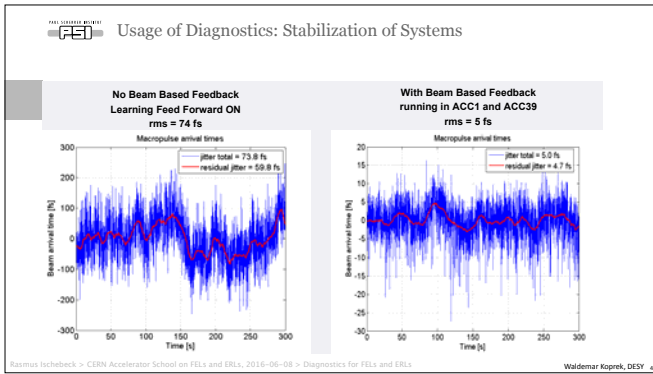

- Asymmetry in the beam caused by mis-alignment

Rasmus Ischebeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs

3

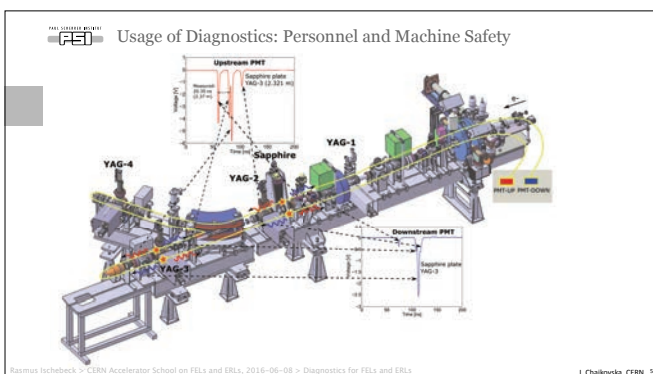

Find errors
 > Errors in beam setup (alignment, phase, ...)
 > Mistakes in hardware setup

Stabilization of systems

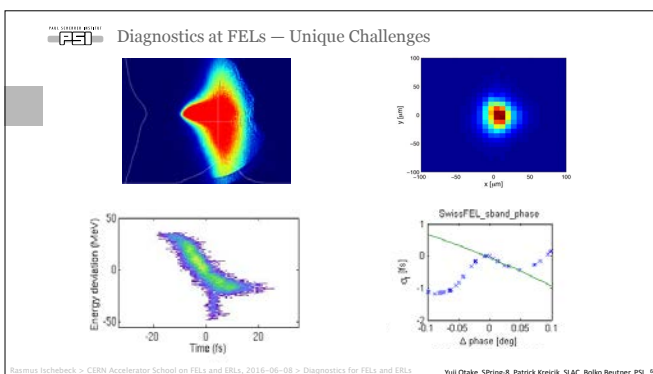

- > measure parameter and automatically adjust accelerator parameters
- > feed-backs
- > here: beam-based feedback of arrival time, acting on RF parameters

Note the different scale on the plots!

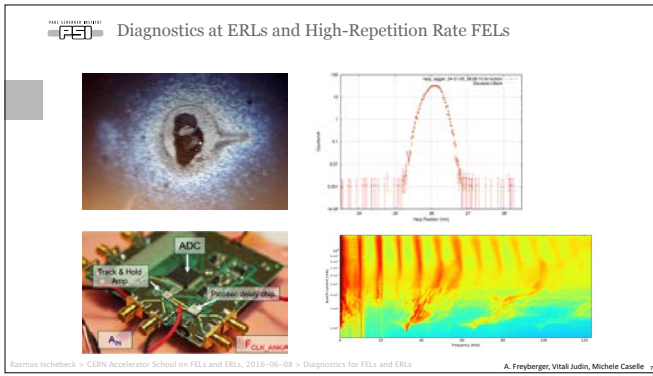

Personnel and machine safety

- > Beam loss detection by Cherenkov radiation in optical fiber
- > Mapping of arrival time to position through propagation speed in the fiber

- > Top left: High brightness: coherent optical transition radiation spoils the usage of OTR as beam profile monitors
- > Top right: Small beam diameters: beam of 14 μm rms size measured in the SwissFEL Injector Test Facility
- > Bottom left: Short pulses shown in this measurement of electron phase space after the undulator at LCLS
- > High accuracy requirements: Simulated dependency of the pulse length on S band phase in the SwissFEL injector

Special challenges:

- > High repetition rate may destroy anything inserted into the beam
- > Halo measurements require large dynamic range
- > Large data sets require special processing

When designing an accelerator, we can carefully choose an instrumentation suite that lets us

- > set up the accelerator
- > measure beam properties
- > control the stability of the machine via feedbacks

Thus, let us distinguish longitudinal and transverse diagnostics. It is not a clear distinction, as we can transform the phase space dimensions, but it's a start.

Let's first have a look at the object of study, the beam.

This beam can be represented by the particle distribution in the six-dimensional phase space, extended by transverse coordinates x and y , transverse angles x' and y' , time t and energy δ .

When we speak about the longitudinal phase space, we mean the projection on these last two dimensions, and in particular the time, which is very difficult to measure with femtosecond accuracy.

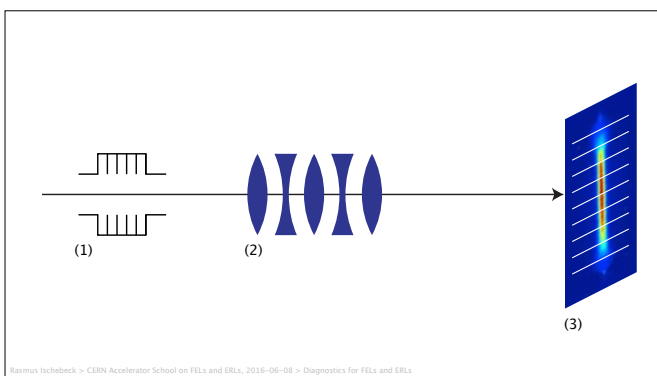

No diagnostics exists for the entire distribution.

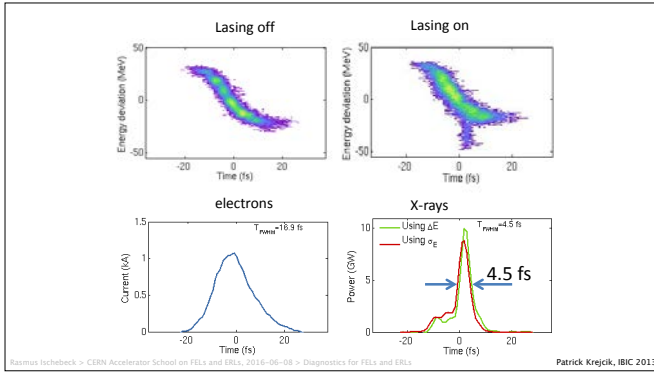

Phase space transformation with RF deflecting cavity
Reference for all longitudinal diagnostics
Shown here: installation in LCLS

Quadrupole magnets result in a phase space transformation between x and x' , and between y and y'

Beam transport
Phase advance with quadrupoles
Detection on screen

Measurements of full phase space possible!
 Femtosecond resolution,
 depending on:
 — emittance
 — streak strength

Skew quadrupoles couple the horizontal coordinates $x-y'$ and $y-x'$
 Skew quadrupoles in dispersive sections (pictured here: bunch compressor) couple energy and transverse coordinates

Integral Measurements
 > Bunch charge
 > Photon pulse energy

Integral Measurements

Rasmus Irschbeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs

Integral measurements

- > Let's first look at diagnostics for integral properties of the beam, i.e. number of electrons / photons
- > Of course, many diagnostics in the next two chapters also measure integral properties
- > What is important here: absolute calibration

Current Transformer

Rasmus Irschbeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs

Wikimedia Commons

Integrating current transformer (ICT)

- > acts like a transformer, but the primary coil is the beam
- > response on secondary coil depends on the number of windings

Photon Pulse Energy

Rasmus Irschbeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs

Kai Tiedtke

X-ray pulse energy measurements

- > Photodiode (for low intensities)
- > Back-scattering from thin membrane
- > Transparent measurement of X-ray pulse energy by ionization of a gas

Absolute measurement of losses:
leakage current in field effect
transistor (FET)

Transverse Diagnostics
 > Beam position monitors
 > Profile monitors:
 > Scintillator
 > Synchrotron radiation
 > Optical transition radiation

Beam position monitors: cavity
pickups

Signal processing, digitization and digital data processing

Very low noise readout of cavity BPMs results in sub-micrometer accuracy

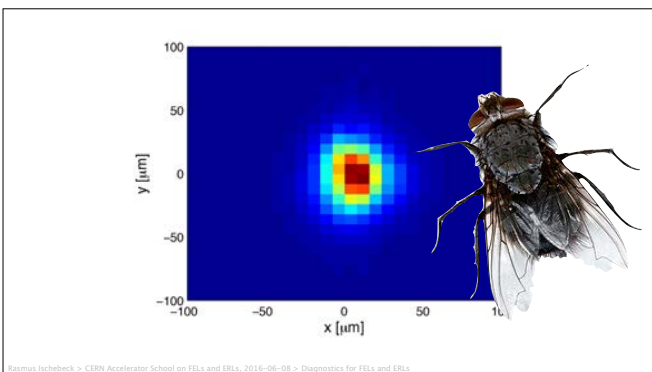

- Low charge: Position-noise \cdot charge = const = 15pC $\cdot\mu$ m
- Q=135pC: Noise <0.8 μ m RMS, \pm 1mm range.
- Charge noise <0.1% (<0.1pC RMS at Q=135pC).

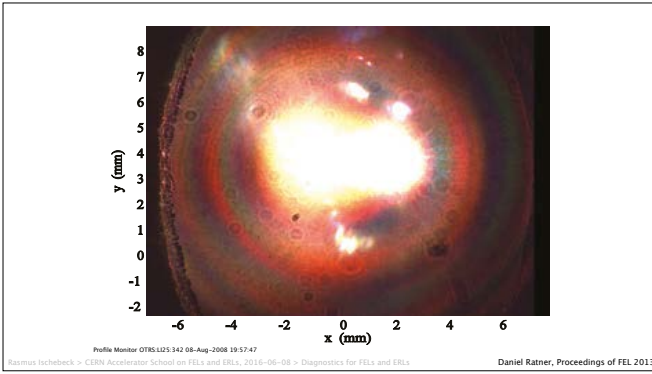

Rasmus Irbachbeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs

Boris Keil

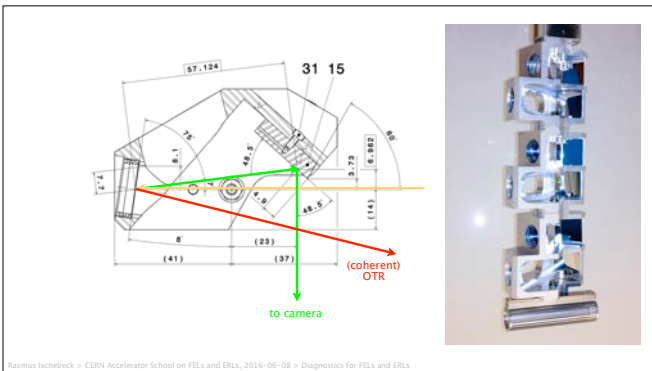

Beams in modern accelerators are small!

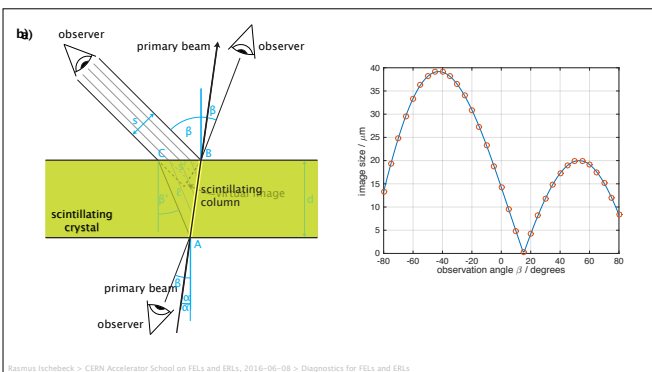

Rasmus Irbachbeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs

...but now: COTR!
 Intense light, has made all the high-energy OTR monitors at LCLS useless

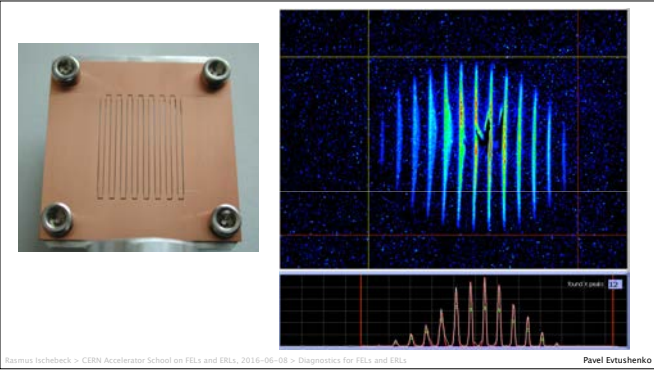

Direct COTR away from the imaging system!
 At the same time, observe
 > Snell's law of refraction
 > Scheimpflug imaging condition

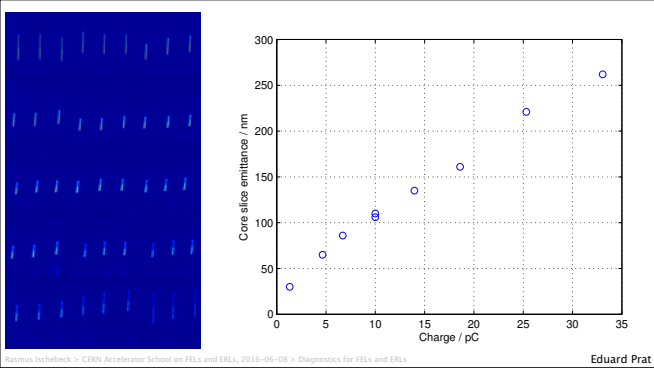

Snell's law of refraction results in an angle-dependent broadening of the virtual image

Measurement of emittance by slits

Rasmus Ischebeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs Pavel Evtushenko

Measurement of small emittances by quadrupole scan
 RF deflector allows measurement of time-resolved beam properties
 > slice emittance
 > beam optics (matching)

Rasmus Ischebeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs Eduard Prat

At high repetition rates (European XFEL):
 Kicking the beam sideways to the screen

Rasmus Ischebeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs J. Wychowaniak et al., Proceedings of FEL 2014

Measurement at ERL: making use of high repetition rate beam to measure emittance by scanning beam across slits

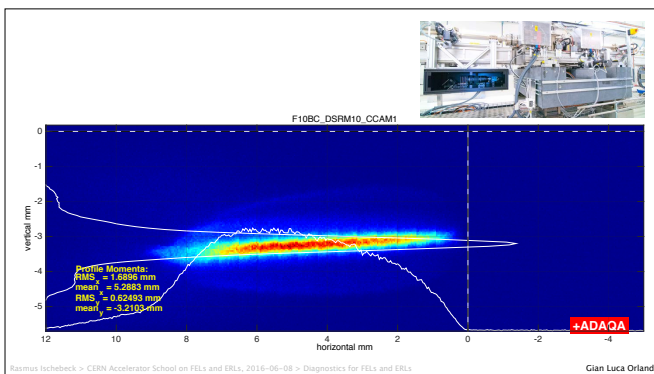

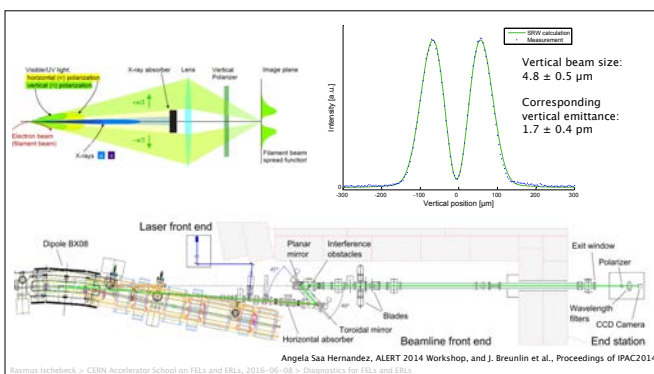

Image from synchrotron radiation monitor

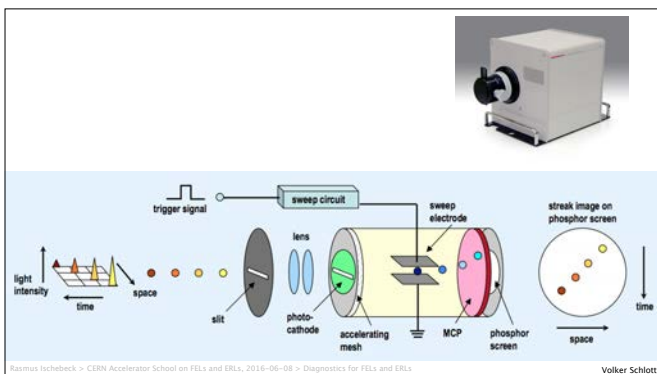

Measurement of synchrotron radiation in storage ring
 > Measurement principle: interference of vertically polarized synchrotron light
 > Measurement of very small beams possible, even at a large distance
 > Requirement: very good knowledge of the beam shape (here: Gaussian)

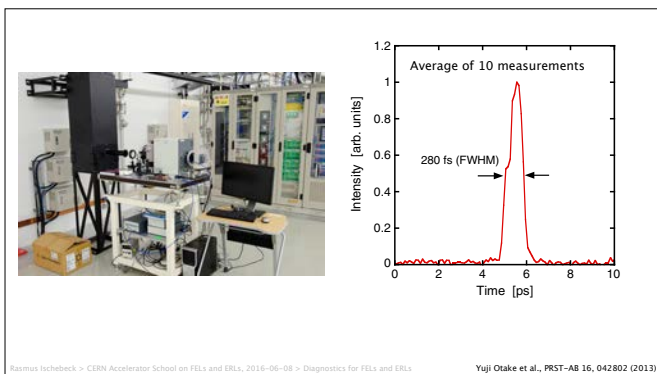

Time-resolved instrumentation is especially challenging at FELs, due to the very short bunches

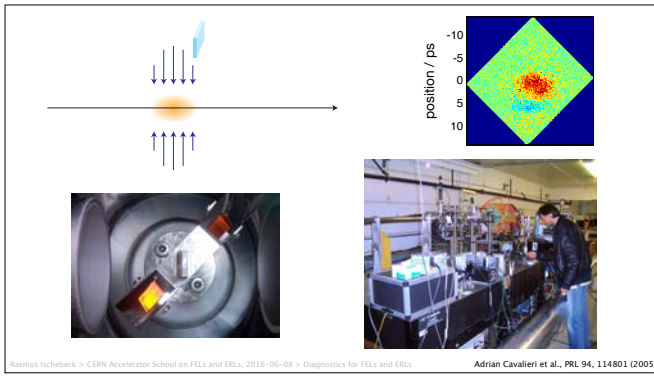

Let's first look at direct time domain methods!

Streak Camera
Traditional method to determine pulse length
Resolution down to ~ 1 ps possible
Commercially available devices

A sub-picosecond time resolution can be achieved with the latest generation streak camera. Shown here: a measurement at SACLA

Rasmus Ischebeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs

Adrian Cavalleri et al., PRL 94, 114801 (2005)

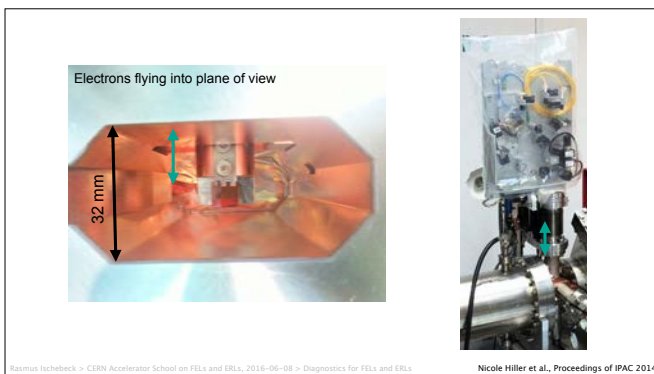

Another method to achieve sub-picosecond resolution is to probe directly the transverse electromagnetic field of the electron bunches. An electro-optic crystal, i.e. one that exhibits the Pockels effect, is introduced into the vacuum chamber, and the change in birefringence is probed by a short laser pulse.

Rasmus Ischebeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs

Bernd Steffen, AFS Inc.

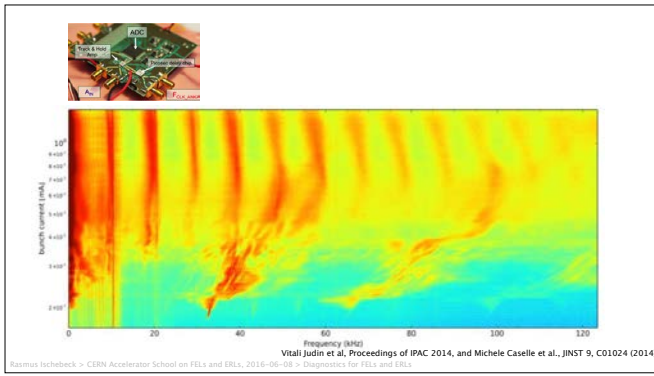

Cross-correlation with an external laser pulse
 Pockels effect allows to cross-correlate coherent THz fields with laser
 Reflectivity change allows to cross-correlate X-rays with laser
 Measure: Bunch arrival time & Bunch length
 Also known as “Electro-optical effect”
 Electric field induces birefringence in crystal
 Birefringence can be probed with a polarized laser
 Pockels Effect can probe down to time scales of 10...100 fs
 Effect is totally reversible

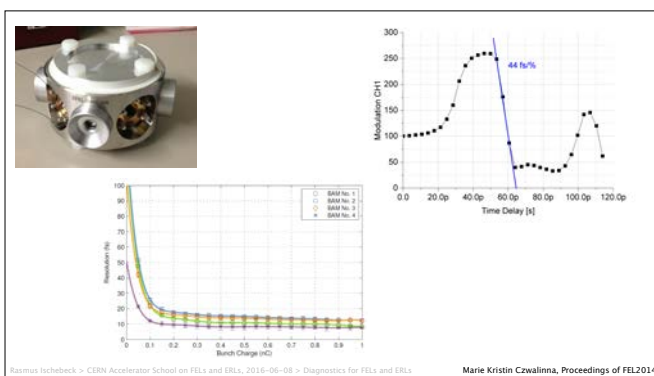

Rasmus Ischebeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs

Nicole Hiller et al., Proceedings of IPAC 2014

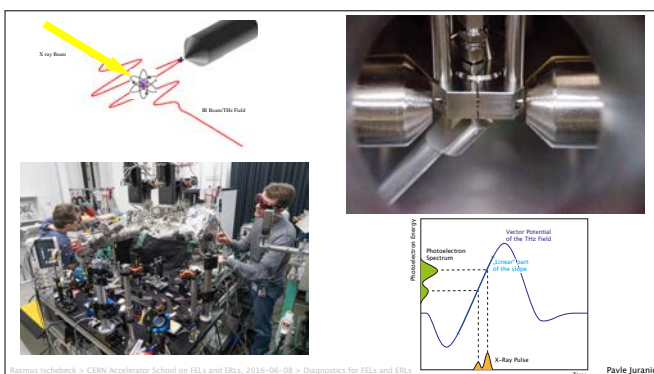

The setup has been transformed from an experiment to a reliable diagnostics. Shown here: electro-optical monitor at the ANKA storage ring, designed in a KIT-DESY-PSI collaboration.

Interesting detail: fast readout of the detector.
 Measurement of instabilities as a function of beam current in a storage ring

Another possibility: put the electro-optical crystal in a box outside the accelerator vacuum, and transmit the EM field through cables.
 —> Possibility to measure arrival time

THz Streak Camera installed at SACLA
 Measurement principle: X-ray photons ionize a gas
 Photoelectron spectrum is equal to photon spectrum minus binding energy
 Additional electromagnetic field (THz) streaks the photoelectrons

Measurements at LCLS confirm sub-cycle pulse length

Spectral Techniques

Another possibility: ignore the phase of the spectrum of the bunch, and measure only spectral amplitude
 —> Stabilization for feedbacks

Reminder: bunch compression

Calculated spectrum, assuming Gaussian bunches, for different compression stages, and for different operation modes of SwissFEL.
Note logarithmic scales on both axes!

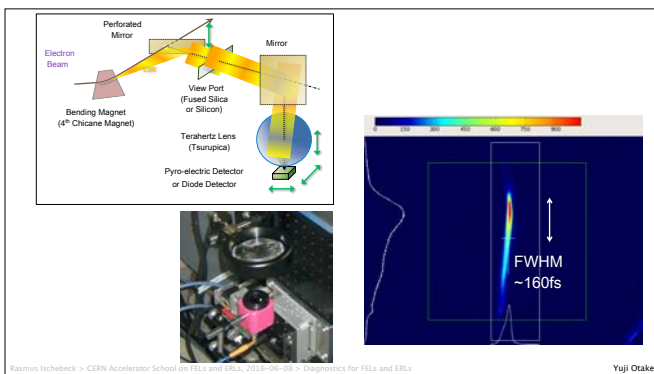

Careful! Ignoring the phase of the radiation means that generally, you cannot reconstruct the bunch length from the spectrum.

Setup at LCLS
Detection of coherent edge radiation from the bunch compressor

Signal peaks at maximum compression

Similar setup at SACLA (free electron laser at SPring8 in Japan)
I will now show a comparison of CSR measurement with bunch length measurements using transverse deflecting cavity

The bunch length observed with the CSR monitor was calibrated by using the RF-deflector's data. Electron beam was bypassed through BC3. Bunch length was changed by the RF phase of the S-band accelerating structures. Estimated bunch length measurement sensitivity is about 6% at a bunch length of 170fs.

CSR intensity as a function of the RF Phase of the C-band accelerating structures before BC3. CSR intensity was linearly changed by the RF phase of the C-band (5712 MHz) accelerating structure before BC3. Estimated bunch length measurement sensitivity is less than 0.1 deg., which is better than that of the RF deflector.

Coming back to the power distribution of CSR, we see that we could improve resolution if we detect selectively near an edge

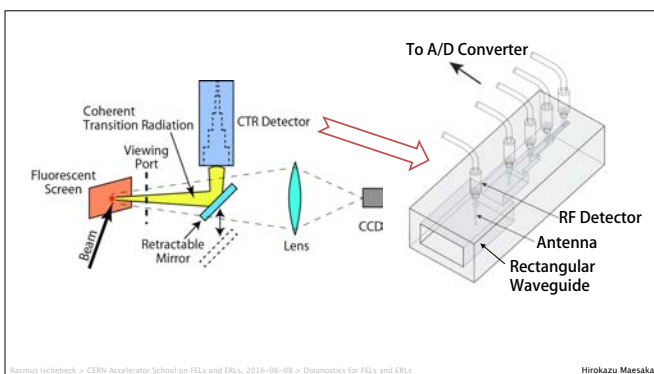

Setup installed at the SwissFEL Injector Test Facility
Beam splitters, then using grids as edge pass filters

Indeed, sensitivity to X-band phase changes (i.e. compression changes) increased when using only high-frequency radiation

This detector is very fast: detection of two bunches separated by 28 ns easily possible

Similar idea: detect different frequency components. Here: five channels separated by waveguides, for GHz frequencies (SACLA after first compression)

Dependency of different frequency signals on compression

THz spectrometer with 120 channels implemented at DESY, for FLASH

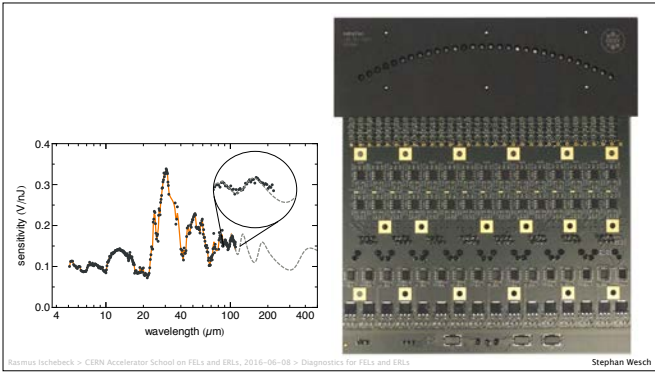

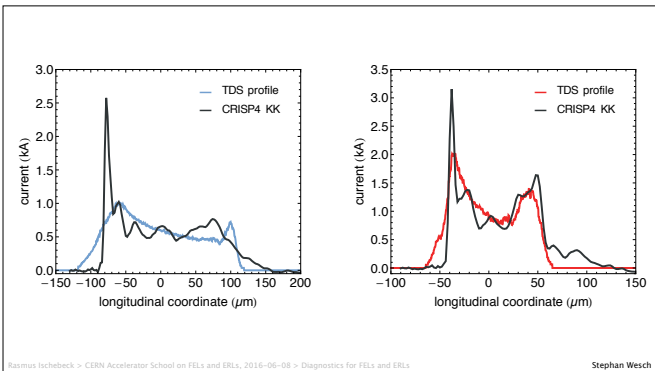

Photo of the setup

Parallel readout of a total of 120 channels in pyro detector arrays

Rasmus Ischebeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs
Stephan Wesch

Rasmus Ischebeck > CERN Accelerator School on FELs and ERLs, 2016-06-08 > Diagnostics for FELs and ERLs
Stephan Wesch

Reconstruction with Kramers-Kronig relation.
Keep in mind: this is the shortest pulse compatible with the spectrum.
The spectrum in itself is also compatible with a bunch length of 4.6 billion years!
