## IMPORTANCE OF THE RESEARCH

Rutherford cables wound with Nb<sub>3</sub>Sn strands will be used in all the high field superconducting magnets required for upgrades to the large hadron collider:

- (1) The high luminosity LHC (High Lumi LHC, HL-LHC, 11 and 12T),
- (2) A higher energy LHC (HE-LHC, 16 T),
- (3) A very high energy future circular collider (FCC, 16 T).

The numerous planned accelerator applications will demand a continuous supply of Nb<sub>3</sub>Sn strand and cables accompanied by vigorous magnet and cable design programs directed towards high field quality magnets.

For this reason we are studying one of the essential components of cable magnetization-- the ramp-rate dependent coupling magnetization,  $M_{coup}$ ,

which is based on the effective interstrand contact resistance,  $R_{eff}$

## Measurements

In support of the US LHC Accelerator Research Program (LARP) the magnetizations of eight LARP high gradient quadrupole cables designated HQ and QXF were measured.

The total magnetization losses ( $Q_{total} = Q_{coupling} + Q_{persistent\ current}$ ) of the cable stacks were measured by **pickup coil magnetometry** at 4.2 K in FO fields,  $B_m$ , of  $\pm 400$  mT at frequencies,  $f$ , of up to 60 mHz.

Based on  $Q_{total}(f)$  i.e.  $Q_{coup}(f)$ , the effective interstrand contact resistance,  $R_{eff}$ , was derived and presented as a function of core cover,  $W$  %.

## Strand and Cable Details

## Data and Analysis for $R_{eff}$ and $M_{coup}$

Figure 1: Total magnetization loss,  $Q$ , as function of frequency,  $f$ , for the H series and QXF series cables. The persistent current components,  $Q_p$ , are the  $f=0$  intercepts. The EO loss was measured calorimetrically

$$Q_{coup(FO)} = \left(\frac{4}{3}\right) \left(\frac{w}{t}\right) L_p B_m \left(\frac{N^2}{20}\right) \left[\frac{1}{R_c} + \frac{20}{N^3 R_a}\right] \left(\frac{dB}{dt}\right) \quad (1)$$

$$Q_{coup(FO)}(f) = \left(\frac{\pi^2}{30}\right) \left(\frac{w}{t}\right) L_p B_m^2 N^2 \left[\frac{1}{R_c} + \frac{20}{N^3 R_a}\right] \cdot f \quad (2)$$

$$= \left(\frac{\pi^2}{30}\right) \left(\frac{w}{t}\right) L_p B_m^2 N^2 \left[\frac{1}{R_{eff}}\right] \cdot f \quad (3)$$

Using Eqn. (3)  $R_{eff}$  is obtained from the experimental  $dQ_{total}/df$ .

Table 3 Experimental  $R_{eff}$  and derived  $R_a^*$

| Cable type              | HQ   |      | QXF  |      |      |      |      |      |
|-------------------------|------|------|------|------|------|------|------|------|
| Stack name              | H1   | H2   | Q1   | Q2   | Q3   | Q4   | Q5   | Q6   |

\* Based on  $R_a = (20/N^3) \cdot R_{eff}$  given an "infinite"  $R_c$

## Acknowledgments

The cables were wound by H.C. Higley (LBNL), heat treated at LBNL (QXF cables) and Brookhaven National Laboratory (A.K. Ghosh, HQ cables). J. Yue and R. Avonce (HyperTech Research) performed the vacuum impregnation.

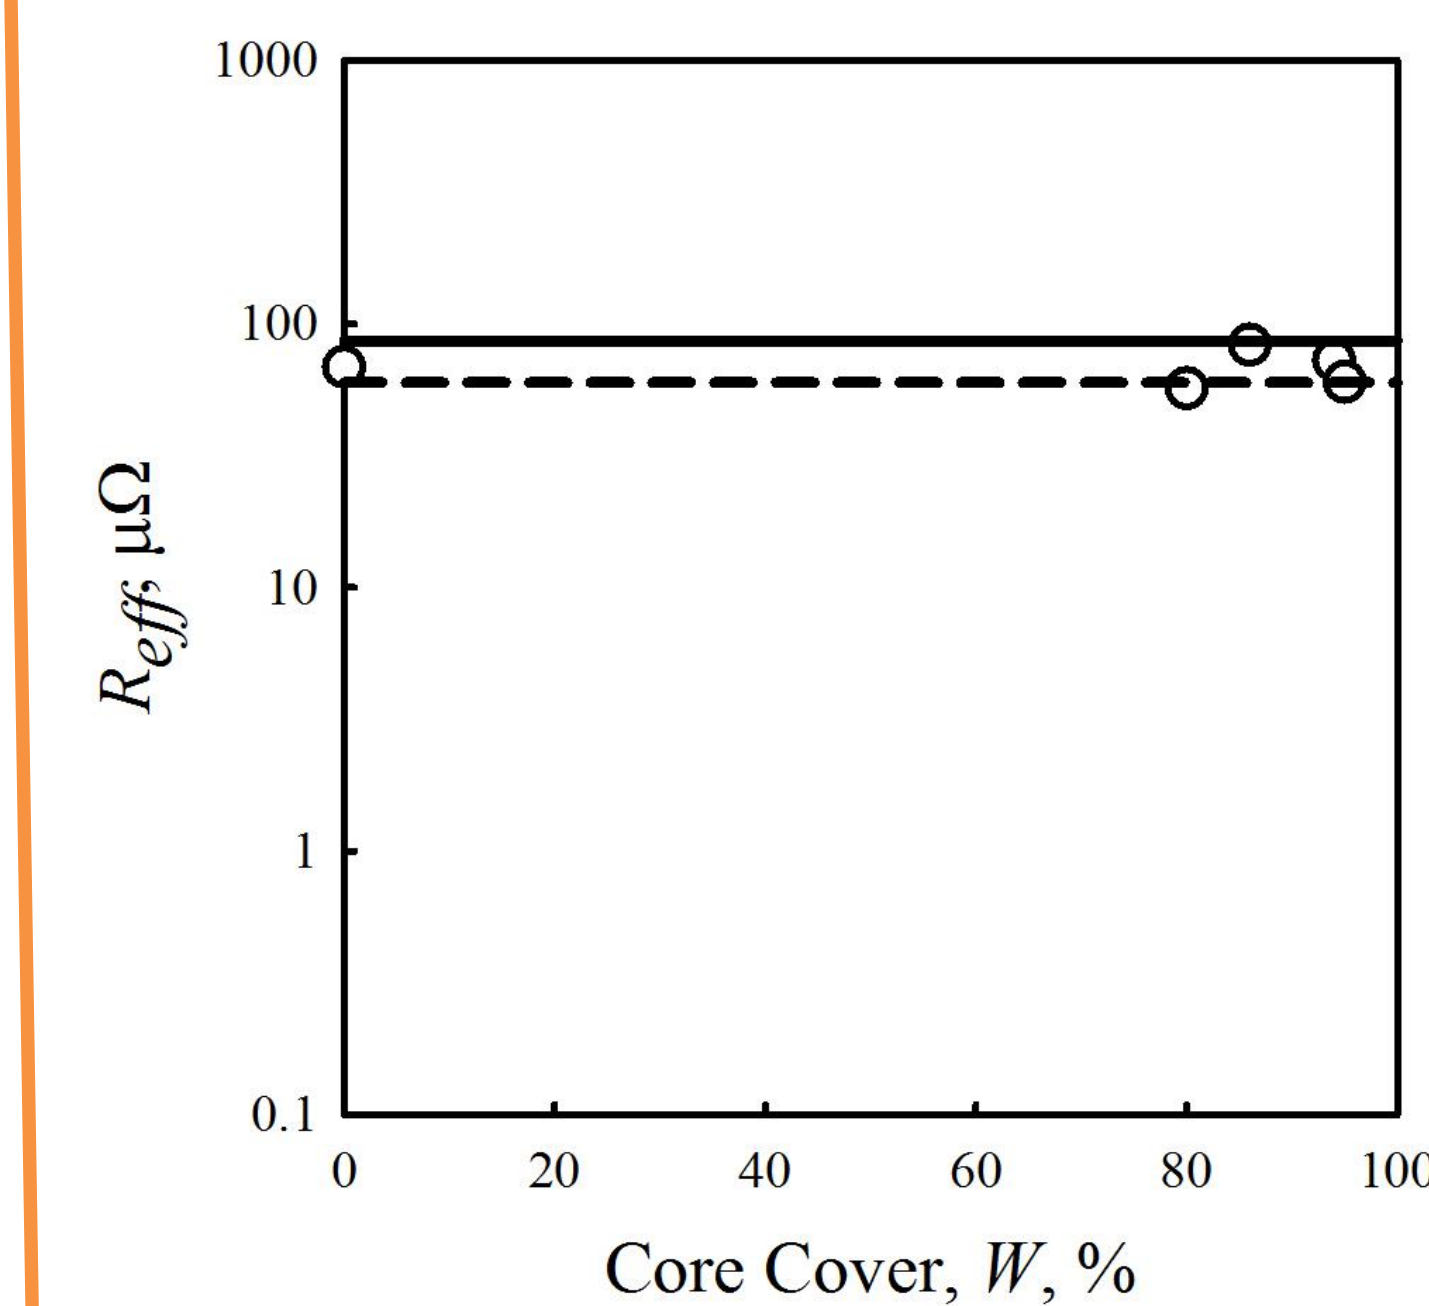

Funding was provided by the U.S. Department of Energy, Office of High Energy Physics, under Grants No. DE-SC0010312 and DE-SC0011721 (OSU) and DE-AC02-05CH11231 (LBNL).

## CUDI<sup>®</sup>-calculated plots of $R_{eff}$ versus core-coverage, $W$ %

## Compacted Cables

Figure 2:  $R_{eff}$  versus core cover for a previously studied assortment of compacted Nb<sub>3</sub>Sn cables (o), the present compacted cables H1 and H2 (■) (see Table 3), and a CUDI<sup>®</sup> simulation (—) based on  $R_c = 0.26 \mu\Omega$  and  $R_a = 0.2 \mu\Omega$

## Uncompacted Cables

Figure 3: Experimental  $R_{eff}$  versus core cover data for QXF cables Q2-Q6 (o).

The lines are CUDI<sup>®</sup> simulations based on  $R_c = 0.1 \Omega$  with  $R_a = 26 \text{ n}\Omega$  (—) and  $18 \text{ n}\Omega$  (---); they represent  $W$ -independent  $R_{eff}$  values of  $86 \mu\Omega$  and  $60 \mu\Omega$ , respectively

## Conclusions

Measurements of the LHC NbTi quadrupoles have yielded  $R_c$  values around  $160 \mu\Omega$ . To raise the  $R_c$  of Nb<sub>3</sub>Sn cables to this level from its "compacted value" of  $0.26 \mu\Omega$  would require the insertion of an insulating core. Removing  $R_c$  from the equations calls for an  $R_a = (20/N^3) \cdot 160 = 50 \text{ n}\Omega$ , consistent with the present results, Table 3.

The **compacted** cable needs a full core to remove  $R_c$  from the equation. Since in the **uncompacted** case the crossing strands are separated by a thick epoxy layer  $R_c$  is essentially "infinite" whether the core is present or not;  $R_c$  is independent of core width, Figure 3. Since there is no guarantee that such a condition could be reproduced from winding to winding it would be advisable to include a full width core.

Still to be determined are the influences of the above  $R_c$  and  $R_a$  values on current sharing and stability.
