Galactic Rotation Curves

Simplified Models / EFTs

Minimal models

Do not aim to be complete description

Parametrize phenomenology by a few masses and couplings

Simplified Models / EFTs

- Parametrize experimental results, sensitivities in the simplest and broadest possible way
 - cMSSM vs simplified models
 - framing the problem to lead to a more faithful mapping of boundaries of what is achievable
- Covering all bases -- lets us find a richer experimental observations, critical in experimental design
 - Dark photons, low-mass dark matter searches
- Model building -- point to new models which achieve a given phenomenology

WIMP Miracle

Thermal relic abundance only depends on annihilation rate

$$\langle\sigma_{Av}\rangle \sim \frac{\lambda^4 m_\chi^2}{32\pi m_\phi^4} \sim \frac{1}{2} \frac{(1.4)^4 (100 \text{ GeV})^2}{32\pi (500 \text{ GeV})^4} \sim 3 \times 10^{-26} \text{ cm}^3/\text{s}$$

Two problems

1. Tension between the WIMP miracle and direct detection signatures

$$\sigma^{(n)} \sim \frac{\lambda^4 m_n^2}{64\pi m_\phi^4} \sim \frac{(1.4)^4 (1 \text{ GeV})^2}{64\pi (500 \text{ GeV})^4} \sim 10^{-40} \text{ cm}^2$$

LUX limits on WIMP-nucleon cross section $\sim \text{zb}$ [10^{-45} cm^2]

2. Generic weak scale interactions severely constrained by flavor

WIMP Flavor Problem

Inherited from models simplified models are inspired from
e.g. SUSY flavor problem

Some simplified models are flavor safe by construction
s-channel vector

General solution parametrized by Minimal Flavor Violation

Minimal Flavor Violation

Flavor constraints strongly hint that flavor violation is encoded in Yukawa matrices

Assume SM flavor symmetry, treating Yukawa couplings as spurions

Assign flavor quantum numbers to all fields, construct invariant interactions

$$\lambda_j^i = (\alpha I + \beta y^\dagger y)_j^i$$

$$[m_\chi]_i^j = (m_0 I + \Delta m y^\dagger y)_i^j$$

Flavored Dark Matter model building

Phenomenology depends crucially on which SM fields DM couples to

b-flavored dark matter

ϕ colored

$$m_{\chi,b} < m_{\chi,s} \simeq m_{\chi,d}$$

$$\lambda_j^i = (\alpha I + \beta y^\dagger y)_j^i$$

$$[m_\chi]_i^j = (m_0 I + \Delta m y^\dagger y)_i^j$$

Tau-flavored dark matter

$$m_{\chi,\tau} < m_{\chi,\mu} \simeq m_{\chi,e}$$

or

$$m_{\chi,\tau} \simeq m_{\chi,\mu} \simeq m_{\chi,e}$$

Skew flavored dark matter

$$\epsilon^{ijk} \chi_i e_j^c \phi_k$$

Direct

Detection

Indirect

Detection

Colliders

Direct

Direct detection

For most models, DM arises at one loop through photon exchange

Can analyze form factors for coupling to the DM current

Example: Fermion dark matter

$$T^{\mu\nu} = \gamma^{\mu} \gamma^{\nu} F(p^2) + \frac{1}{2m^2} F_S(p^2) + \frac{1}{2m^2} F_T(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_A(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_P(p^2)$$

charge magnetic dipole moment electric dipole moment anapole moment

Direct detection

Self-conjugate particles

Real scalar, Majorana fermions, real vector

Example: Majorana fermion dark matter

$$T^{\mu\nu} = \frac{1}{2} \gamma^{\mu} \gamma^{\nu} F(p^2) + \frac{1}{2m^2} F_S(p^2) + \frac{1}{2m^2} F_T(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_A(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_P(p^2)$$

Only non-zero form factor is P-odd Anapole moment

Leads to velocity-suppressed scattering amplitudes

$$\chi^2 \propto v^4 \epsilon^2$$

Direct detection

Less significant only for complex scalar and Dirac fermion

Form factors: F_S, F_T, F_A, F_P

$$F_S = \frac{1}{2} \gamma^{\mu} \gamma^{\nu} F(p^2) + \frac{1}{2m^2} F_S(p^2) + \frac{1}{2m^2} F_T(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_A(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_P(p^2)$$

$$F_T = \frac{1}{2} \gamma^{\mu} \gamma^{\nu} F(p^2) + \frac{1}{2m^2} F_S(p^2) + \frac{1}{2m^2} F_T(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_A(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_P(p^2)$$

$$F_A = \frac{1}{2} \gamma^{\mu} \gamma^{\nu} F(p^2) + \frac{1}{2m^2} F_S(p^2) + \frac{1}{2m^2} F_T(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_A(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_P(p^2)$$

$$F_P = \frac{1}{2} \gamma^{\mu} \gamma^{\nu} F(p^2) + \frac{1}{2m^2} F_S(p^2) + \frac{1}{2m^2} F_T(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_A(p^2) + \epsilon^{\mu\nu\alpha\beta} \partial^{\rho} p^{\sigma} F_P(p^2)$$

Direct detection

$$M = \frac{1}{2} \sum_{\mu, \nu} \langle N_{\mu} \rangle \langle N_{\nu} \rangle \langle N_{\mu} \rangle \langle N_{\nu} \rangle$$

$$F = \frac{1}{2} \sum_{\mu, \nu} \langle N_{\mu} \rangle \langle N_{\nu} \rangle \langle N_{\mu} \rangle \langle N_{\nu} \rangle$$

$$F_S = \frac{1}{2} \sum_{\mu, \nu} \langle N_{\mu} \rangle \langle N_{\nu} \rangle \langle N_{\mu} \rangle \langle N_{\nu} \rangle$$

$$F_T = \frac{1}{2} \sum_{\mu, \nu} \langle N_{\mu} \rangle \langle N_{\nu} \rangle \langle N_{\mu} \rangle \langle N_{\nu} \rangle$$

$$F_A = \frac{1}{2} \sum_{\mu, \nu} \langle N_{\mu} \rangle \langle N_{\nu} \rangle \langle N_{\mu} \rangle \langle N_{\nu} \rangle$$

$$F_P = \frac{1}{2} \sum_{\mu, \nu} \langle N_{\mu} \rangle \langle N_{\nu} \rangle \langle N_{\mu} \rangle \langle N_{\nu} \rangle$$

Leads to velocity-suppressed scattering cross-section $\sim 4 \times 10^{-10} \text{ cm}^2$

Preparation for upcoming direct detection experiments

Detection

Direct detection

For most models, DD arises at one loop through photon exchange

Can analyze form-factors for coupling to the EM current

Example: Fermion dark matter

$$\Gamma^\mu = \gamma^\mu F_1(q^2) + \frac{i\sigma^{\mu\nu}q_\nu}{2m} F_2(q^2) + \frac{i\sigma^{\mu\nu}q_\nu\gamma^5}{2m} F_3(q^2) + (\gamma^\mu q^2 - \not{q}q^\mu)\gamma^5 F_A(q^2)$$

charge
form-factor

magnetic
dipole moment

electric dipole
moment

anapole moment

Direct detection

Self-conjugate particles

Real scalar, Majorana fermions, real vector

Example: Majorana fermion dark matter

$$\Gamma^\mu = \cancel{\gamma^\mu F_1(q^2)} + \cancel{\frac{i\sigma^{\mu\nu}q_\nu}{2m} F_2(q^2)} + \cancel{\frac{i\sigma^{\mu\nu}q_\nu\gamma^5}{2m} F_3(q^2)} + (\gamma^\mu q^2 - \not{q}q^\mu)\gamma^5 F_A(q^2)$$

Only non-zero form factor is P-odd Anapole moment

Leads to velocity-suppressed scattering amplitudes

$$\bar{\chi}\gamma^\mu\gamma^5\chi\bar{q}\gamma_\mu q$$

Direct detection

Limit significant only for complex scalar and Dirac fermion

Exception:

Dark matter and mediator are highly degenerate

[Kopp, Michaels, Smirnov 2014]

$$\mathcal{O}_1 = [\bar{\chi}\gamma^\mu(c + d\gamma^5)\partial^\nu\chi + \text{h.c.}] F_{\mu\nu},$$

$$\mathcal{O}_2 = [i\bar{\chi}\gamma^\mu(c + d\gamma^5)\partial^\nu\chi + \text{h.c.}] F^{\sigma\rho}\epsilon_{\mu\nu\sigma\rho}$$

$$\Gamma^\mu = \gamma^\mu F_1(q^2) + \frac{i\sigma^{\mu\nu}q_\nu}{2m} F_2(q^2) + \frac{i\sigma^{\mu\nu}q_\nu\gamma^5}{2m} F_3(q^2) + (\gamma^\mu q^2 - \not{q}q^\mu)\gamma^5 F_A(q^2)$$

$$\mathcal{M} = \tilde{\lambda} \sum_q \langle N_f | Q \bar{q} \gamma_\alpha q | N_i \rangle \bar{u}(p_2) \gamma^\alpha u(p_1)$$

$$\tilde{\lambda} \sim \frac{\alpha}{4\pi} \frac{\lambda^2}{m_\phi^2} \log \left[\frac{m_l^2}{m_\phi^2} \right]$$

Direct detection

$$\mathcal{M} = \tilde{\lambda} \sum_q \langle N_f | Q \bar{q} \gamma_\alpha q | N_i \rangle \bar{u}(p_2) \gamma^\alpha u(p_1)$$

$$\tilde{\lambda} \sim \frac{\alpha}{4\pi} \frac{\lambda^2}{m_\phi^2} \log \left[\frac{m_l^2}{m_\phi^2} \right]$$

$$\langle \sigma_{Av} \rangle \sim \frac{\lambda^4 m_\chi^2}{32\pi m_\phi^4} \sim \frac{1}{2} \frac{(1.4)^4 (100 \text{ GeV})^2}{32\pi (500 \text{ GeV})^4} \sim 3 \times 10^{-26} \text{ cm}^3/\text{s}$$

$$\sigma^{(n)} \sim \frac{\tilde{\lambda}^2 m_n^2}{4\pi} \sim \left(\frac{\alpha}{4\pi} \log \left[\frac{m_l^2}{m_\phi^2} \right] \right)^2 \frac{(1.4)^4 (1 \text{ GeV})^2}{64\pi (500 \text{ GeV})^4} \sim 10^{-45} \text{ cm}^2$$

LUX limits on WIMP-nucleon cross section $\sim \text{zb} [10^{-45} \text{ cm}^2]$

Promising for upcoming direct detection experiments

b-flavored dark matter

$$m_{\chi,b} < m_{\chi,s} \simeq m_{\chi,d}$$

Annihilation to b-quarks

"Safe" from direct detection

Colored mediator has stringent constraints

b-flavored dark matter

$$m_{\chi,b} < m_{\chi,s} \simeq m_{\chi,d}$$

Annihilation to b-quarks

"Safe" from direct detection

Colored mediator has stringent constraints

3.5 keV Line(s)

Dark matter couples to right-handed leptons

$$m_{\chi,\tau} \simeq m_{\chi,\mu} \simeq m_{\chi,e}$$

Mass splittings generated radiatively

$$\frac{\Delta m_{ij}}{m_\chi} \simeq \frac{\lambda^2 (y_{\ell,i}^2 - y_{\ell,j}^2)}{64\pi^2} \frac{v^2}{m_\phi^2} F(m_\chi^2/m_\phi^2)$$

3.5 keV Line(s)

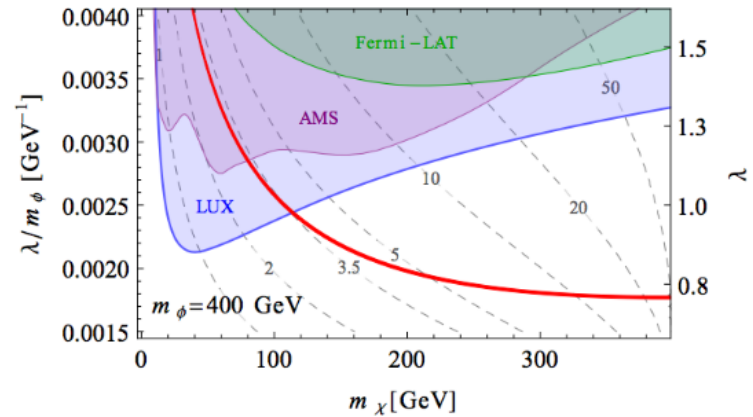

Heavier flavors can be cosmologically stable

Dipole transitions can produce lines

$$\delta\omega = \omega(\chi_\tau \rightarrow \chi_e) - \omega(\chi_\tau \rightarrow \chi_\mu)$$

$$\approx \omega_0 \frac{m_\mu^2}{m_\tau^2} = 12.4 \text{ eV}$$

Colliders

Collider constraints

Colored mediators have large rates
 Consider uncolored mediators

$m_{\chi_{i,1}} < m_{\chi_{i,2}} \approx m_{\chi_{i,3}}$

Production of the mediator like right-handed sleptons

Collider constraints
 Monophoton

$e^+e^- \rightarrow \chi\chi\gamma$

EFT approach for heavy mediators

(Fey, Hamik, Kepp, Tai 2011)

Need simplified models for Hadron colliders

Collider constraints
 LHC limits on right-handed sleptons

Two leptons + MET

CMS (1605.2530)

ATLAS (1605.0294)

Large room for discovery

Collider constraints
 Long decay chains with many leptons

Can identify Flavored Dark Matter by charge-flavor correlations

Summary

Flavored dark matter models are a generic possibility

Phenomenology of these models is distinct from WIMPs

Can naturally hide from direct detection

Can lead to promising indirect detection signatures,
interesting collider signals

Unconventional models are important to keep in mind to
fully utilize the potential of future experiments
