This surface is called the “stationary” surface of order k and denoted by Σ_k .

$C^\infty(\Sigma_k)$ is the space of smooth functions on that surface.

When we do not specify k in the statement of a property, it means that this property is valid for all k 's.

The phase space Π of a gauge theory can be covariantly described as the space of solutions to the equations of motion modulo the gauge transformations.

Formally, Π is the quotient space $\Pi = \Sigma / \mathcal{O}$ of the stationary surface Σ by the gauge orbits \mathcal{O} generated by the gauge transformations.

The recognition of the antifields as related to a resolution of the stationary surface is key to the formulation of BRST theory beyond Yang-Mills.

(1) When the gauge transformations are reducible, one needs ghosts of ghosts and their conjugate antifields to maintain the resolution property.

(2) When the gauge transformations are "open" (on-shell closure only), the construction is more elaborate because $\gamma^2 \neq 0$, but $\gamma^2 \approx 0$ (only on-shell). This requires additional terms in s ,

$$s = \delta + \gamma + s_1 + s_2 + \dots$$

to guarantee $s^2 = 0$.

Conclusions

The recognition of the antifields as related to a resolution of the stationary surface is key to the formulation of BRST theory beyond Yang-Mills.

(1) When the gauge transformations are reducible, one needs ghosts of ghosts and their conjugate antifields to maintain the resolution property.

(2) When the gauge transformations are “open” (on-shell closure only), the construction is more elaborate because $\gamma^2 \neq 0$, but $\gamma^2 \approx 0$ (only on-shell). This requires additional terms in s ,

$$s = \delta + \gamma + s_1 + s_2 + \dots$$

to guarantee $s^2 = 0$.

This is the Batalin-Vilkovisky construction, which works because the Koszul-Tate complex is a resolution.

Conclusions

A crucial element in the computation of $H_m(s|d)$ is the homology $H_m(\delta|d)$, defined similarly through

$$\delta\omega + da = 0 \quad \text{and} \quad \omega = \delta\psi + db$$

Now, while $H_m(\delta) = 0$ for $m > 0$,

it turns out not to be true that $H_m(s|d) = 0$ for $m > 0$.

A crucial element in the computation of $H_m(s|\mathcal{d})$ is the homology $H_m(\delta|\mathcal{d})$, defined similarly through

$$\delta\omega + da = 0 \quad \text{and} \quad \omega = \delta\psi + db$$

Now, while $H_m(\delta) = 0$ for $m > 0$,

it turns out not to be true that $H_m(s|\mathcal{d}) = 0$ for $m > 0$.

For instance an abelian ghost C^* fulfills $\delta C^* = \partial_\mu A^{*\mu}$ and defines a non-trivial element of $H_2(\delta|\mathcal{d})$.
