## The LZ Dark Matter detector

*Monday, 7 December 2015 18:30 (3 minutes)*

LZ is a second-generation dark-matter experiment designed to achieve unprecedented sensitivity to weakly interacting massive particles (WIMPs) of masses from a few GeV/c to hundreds of TeV/c<sup>2</sup>. With total liquid xenon mass of about 10 tonnes, LZ is planned to achieve a sensitivity to WIMP-nucleon spin-independent cross section approaching  $\sim 2 \cdot 10^{-48}$  cm<sup>2</sup> in 3 years of operation. This represents an improvement of almost three orders of magnitude over current results, covering a substantial range of theoretically-motivated dark matter candidates. We will present aspects of LZ's designs that permit achievement of this planned sensitivity.
