

ASTROPARTICLES

ESIPAP - 2016

François Montanet

Plan of the course

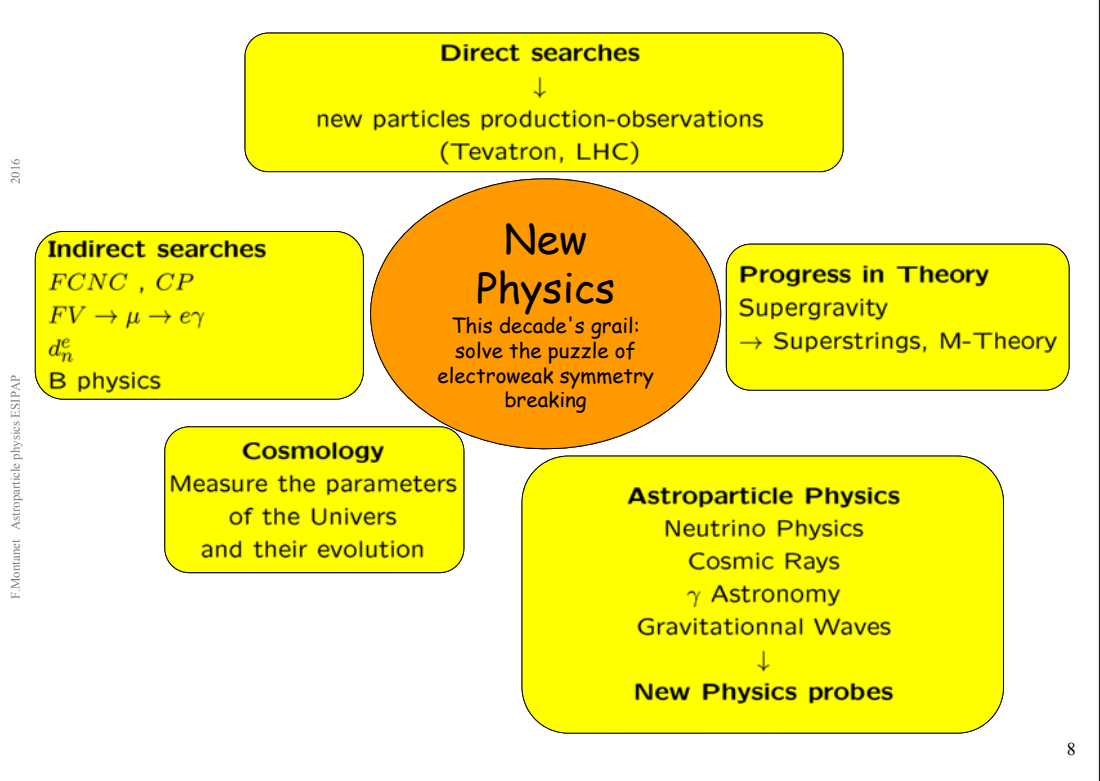

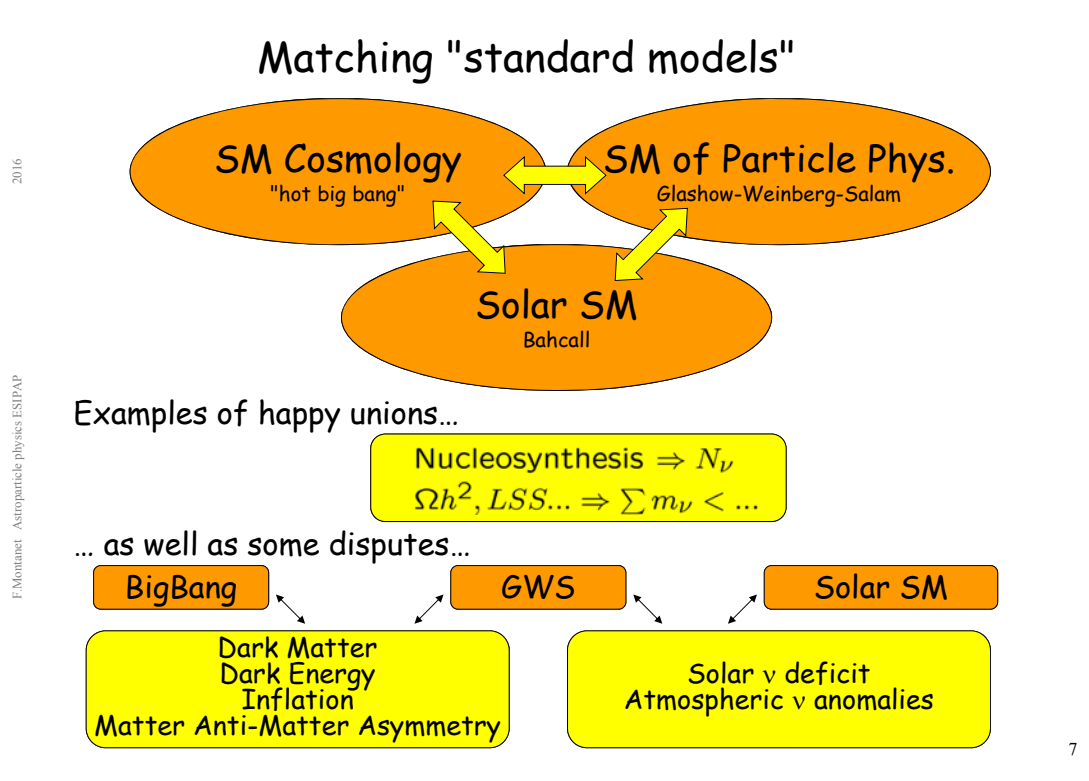

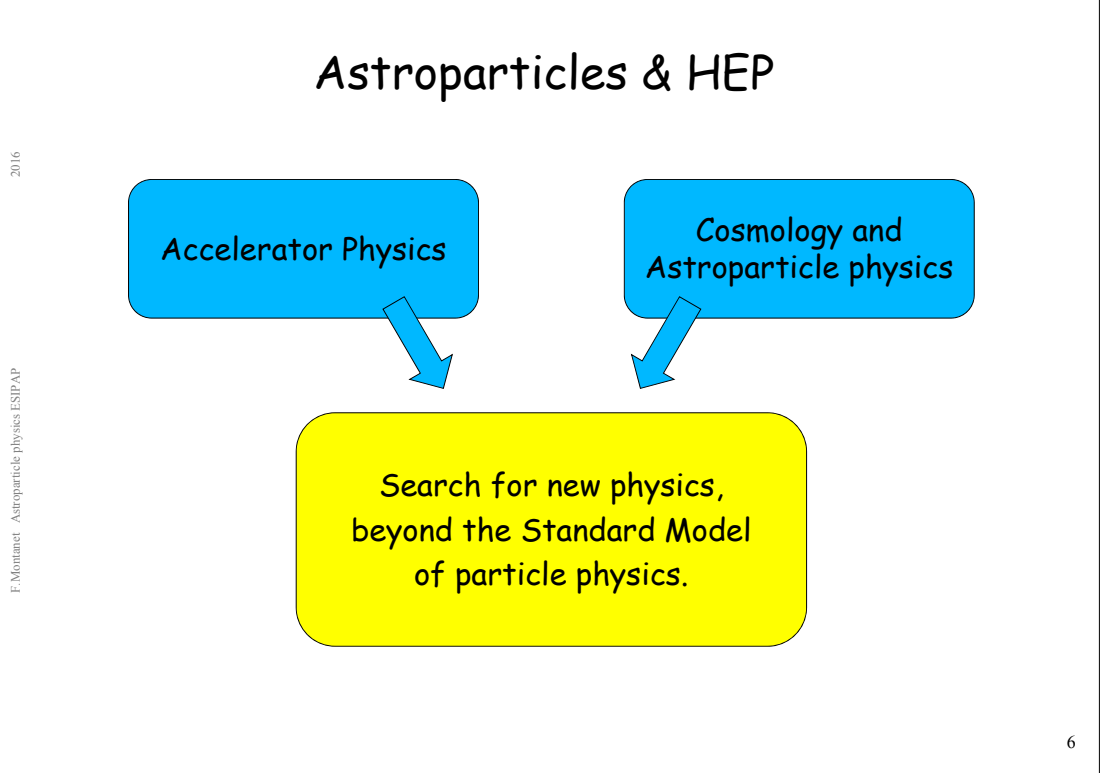

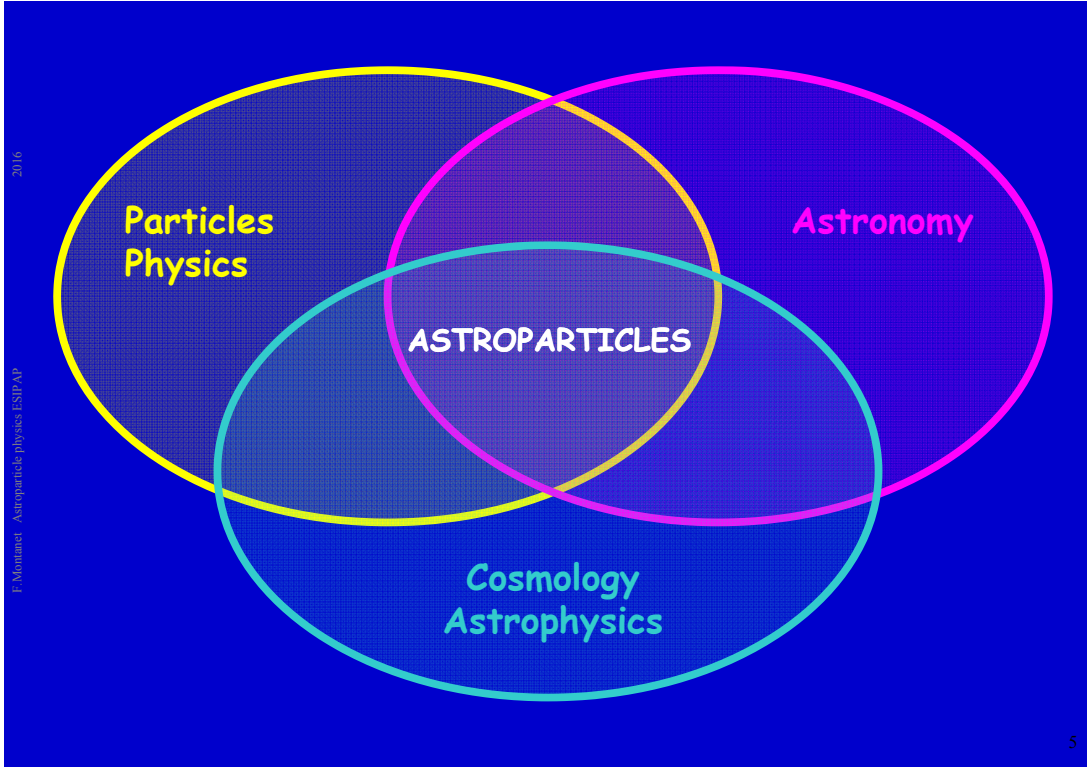

- Introduction + very brief History
- Nature and properties of Astroparticles
- Propagation medium, IGM, ISM and atmosphere
- Astrophysical Sources
 - Astrophysical shocks
 - Fermi acceleration
 - Standard Model for the production of galactic CR, SNR
 - Gamma-ray sources, pulsars
 - AGN and other extragalactic sources
 - Neutrinos sources
- Cosmological Sources
 - Cosmological implications
 - Dark Matter as a source of CR
 - "top-down" type of sources at UHE
- Propagation
 - CR propagation in the Galaxy: The Leaky box model
 - VHE γ -rays propagation
 - UHECR propagation
 - Air Showers Development
- Observables & Observations
 - Primary CR detection (on top of atmosphere)
 - Gamma-ray (EM) induced showers detection => my lecture on Cherenkov det.
 - Hadronic Showers Models and Detection
 - UHECR detection => my lecture on Cherenkov det
- Dark matter search (very briefly on this, covered by J.Macias + U.Oberlack)
- Neutrino Physics with astroparticules (briefly on this, overlaps with other lecturers & detection discussed in my lecture on Cherenkov det)
- Gravitational waves (not covered, very specific)

Why studying Astroparticles

Open questions

Understand our Universe at extreme scales

- The Higgs boson or the origin of mass
- Nature and mass of Neutrinos
- Fundamental symmetries: CP, supersymmetry
- New dimensions in physical space?
- What is our Universe made of?
- Sources and propagation of cosmic rays?
- New Physics at $E \gg E(\text{LHC})$?

13,8 BILLION YEARS AGO,
A FEW SECONDS BEFORE THE
CREATION OF OUR UNIVERSE...

MREU

2016 F. Montanet - Astroparticle physics ESPAP

What are "Astroparticles"

What we know

Let there be light !

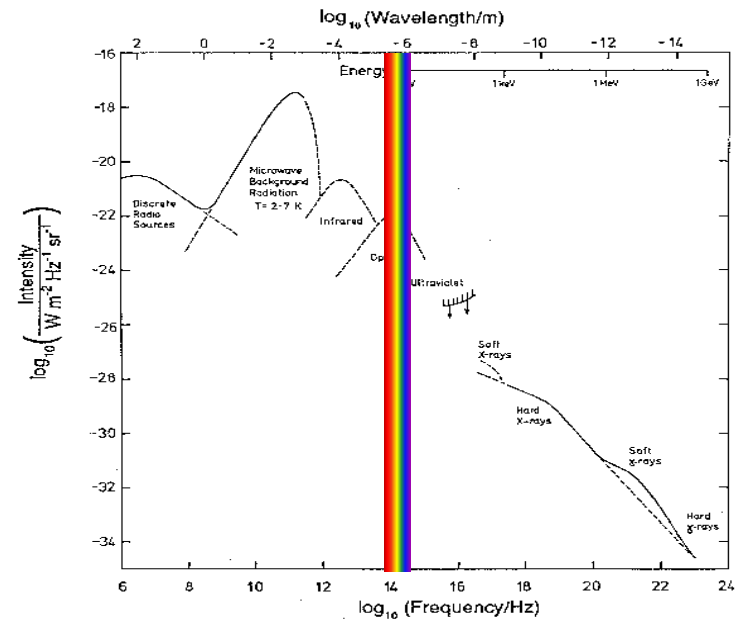

All what we know in astrophysics is thanks to the light !

- Temperatures, stars masses, galaxies, magnetic fields, chemical composition, age of stars and structures...
- Nuclear reactions, galactic and extragalactic hydrodynamics, MHD, explosions, nucleosynthesis, past, future... EVERYTHING !

Well, almost everything...

2016 F. Montanet - Astroparticle physics ESPAP

A multi-wavelength sky

2016 F. Montanet - Astroparticle physics ESPAP

Our Galaxy

The optical Milky Way

Our Galaxy

The optical Milky Way

Our Galaxy

The Milky Way : Radio at 73cm

408 MHz / 73.5 cm / $1.6 \cdot 10^{-6}$ eV

Essentially from the movement of ultra relativistic electrons probably issue from supernovae remnants in the galactic magnetic field.

Our Galaxy

The Milky Way : Radio at 21 cm

(~ 1.42 GHz / 21.1 cm / $5.9 \cdot 10^{-6}$ eV)

Hyperfine transition of hydrogen. Structures are due to the column density of atomic hydrogen clouds along the line of sight.

Our Galaxy

The Milky Way : Radio at 2,6mm

Millimetric waves (115 GHz / 2.6 mm / $4.7 \cdot 10^{-4}$ eV)

Rotation mode ray of carbon monoxide. One assumes that CO abundance is proportional to that of cold molecular hydrogen (directly undetectable).

Our Galaxy

Infra red

Infrared (3 10^3 to 25 10^3 GHz / 100 to 12 μ m / 0.01 to 0.1 eV)

Thermal emission, due to interstellar dust heated by starlight.

Our Galaxy

It structure is clearly visible in IR (COBE satellite).

Near Infrared (86 10^3 à 240 10^3 GHz / 1.25 à 3.5 μ m / 0.35 à 1 eV).

Giant stars emission in the disk and in the bulb

Our Galaxy

Optical

Visible (460 10^3 GHz / 0.65 μ m / 2 eV – red)

Visible light is absorbed by interstellar dust clouds. Only stars close enough to the solar system (few parsec) are seen.

Our Galaxy

X-rays

X-rays ($60 \cdot 10^6$ to $360 \cdot 10^6$ GHz / 5 to 8.3 nm / 0.25 to 1.5 keV).

Diffuse X-ray emission from overheated and shocked gas.

Our Galaxy

Gamma-rays

Gamma-rays ($> 2.4 \cdot 10^{13}$ GHz / < 12.5 fm / > 100 MeV).

Photons (gammas) from the decay of neutral pions produced in the interaction of CR with interstellar matter, from the Bremsstrahlung of CR and from the inverse Compton of relativistic electrons with ambient photons.

Our Galaxy

HE gamma-rays (> 100 MeV EGRET satellite)

Resolved point-like sources:

Binary systems, pulsars, SN remnants...

Centaurus A

Let there be light !

All what we know in astrophysics is thanks to the light !

- Temperatures, stars masses, galaxies, magnetic fields, chemical composition, age of stars and structures...
- Nuclear reactions, galactic and extragalactic hydrodynamics, MHD, explosions, nucleosynthesis, past, future... EVERYTHING !
- Well, almost everything...
 - Non-luminous messengers : CR !
 - Rare but precious : $\sim 4 \text{ CR/cm}^2/\text{s}$
 $\sim 30 \mu\text{g/s}$ on entire earth (1kg per year !)
- CR astronomy is impossible...
 - Directions randomized by magnetic fields
 - What we would know if it was the same for photons !

...but not astrophysics !

- Energy spectra and chemical composition tells us a lot...

Cosmic-rays spectrum

The "all particles" spectrum

- Regular spectrum over 12 decades in energy, and 32 decades in flux !!!
- Small break near $3 \times 10^{15} \text{ eV}$: the "knee"
- An other one near 10^{18} eV : the "ankle"
- Spectrum badly known at the two extremities
 - Geomagnetic "shield" + Solar modulation
 - Extreme rareness...

CR Spectrum above a TeV

Charge cosmic rays composition

2016
F.Montanet - Astroparticule physique ESPAP

Identified spectra

Overview of CR data on composition

- **Chemical composition**
 - Nuclei = 98% (H = 87%, He = 12%, "metals" = 1%)
 - Electrons = 2%
 - More or less standard composition (i.e. solar system) except for fewer H and He, presence of secondary nuclei, and a few "anomalies"...
- **Secondary atoms**
 - Li, Be, B : spallation of C, N, O (+ nuclei below the Fe peak)
 - Nuclear thicknesses traversed by CR : $X_{CR} = 6$ to 10 g/cm²
- **Isotopic anomalies**
 - ²²Ne → link with massive stars
- **Cosmic clocks**
 - ¹⁰Be → ¹⁰B, $\tau \approx 4 \times 10^6$ years (as well as ²⁶Al, ³⁶Cl, ⁵³Mn, ⁵⁴Mn, ⁵⁹Ni)
 - $\tau_{RC} \approx 2 \times 10^7$ years
 - $\frac{X_{RC}}{c\tau_{RC}} \approx 0.2 \text{ part/cm}^3 \Rightarrow$ CR halo extention ($\approx 3-7$ kpc)

2016
F.Montanet - Astroparticule physique ESPAP

Nature of cosmic rays

Abundances different in CR and local measurements (Li Be B and Sub-Fe)

CR undergo spallations and produce secondary CR

2016
F.Montanet - Astroparticule physique ESPAP

Nature of primary cosmic rays

Solar modulation

Data from AMS on ISS

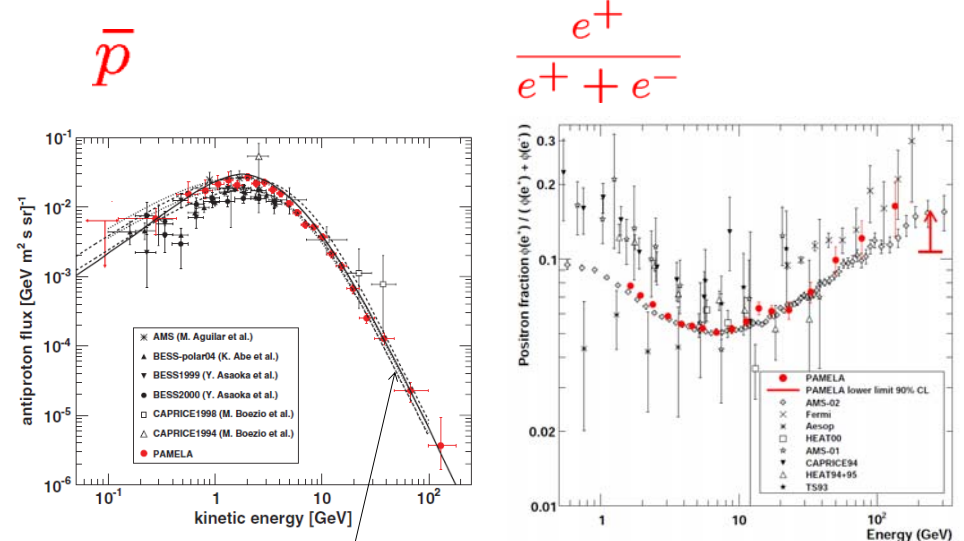

Electron primary flux

Nature of primary cosmic rays

Antimatter ?

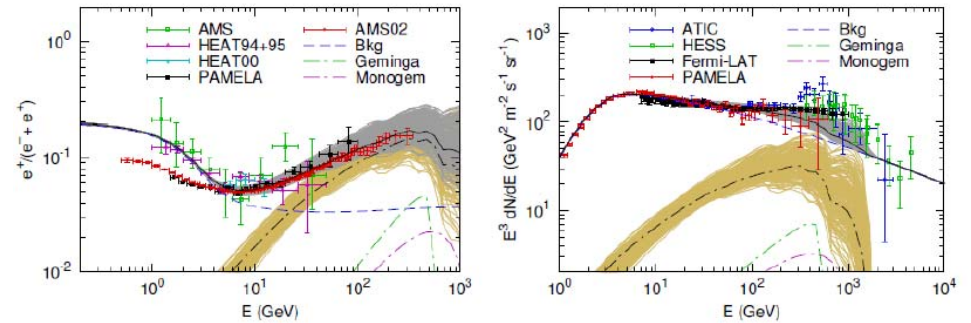

Pure secondary (standard) propagation

Positron fraction in primary flux

Antimatter search (Dark Matter ?)

... or rather a boring "local" pulsar spoiling physicists dreams !

Gamma rays

- Gamma-rays observed → TeV
- Spectrum ± understood up to MeV.
- Above, the diffuse spectrum and that of sources are very "hard", in $1/E^2$ and of still unclear origin...

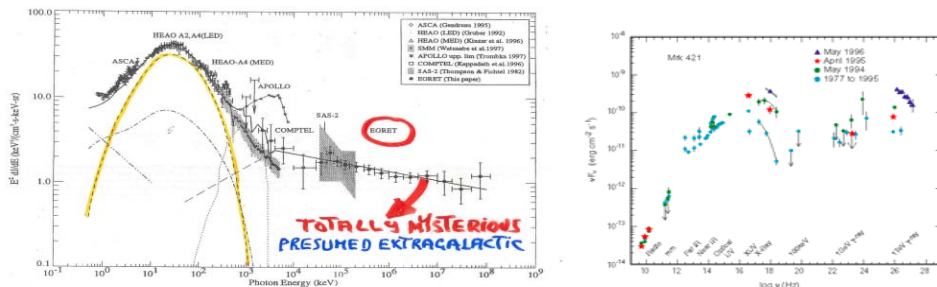

FIG. 10.—Multiwavelength spectrum of the extragalactic gamma-ray spectrum from X-rays to high-energy gamma rays. The estimated contribution from SNR 420 (blue-dashed line), and SNR 420 (black-dotted line) from the model of *Chen et al. (1999)*. The spectrum shows a transition from a power-law (dotted line) to a steeply falling spectrum (dashed line) from *Chen, Falgarone, & Greenberg (1997)*. Type Ia supernovae (dotted line) from *Chen et al. (1993)*. The linear contribution below 4 MeV (dashed-dotted line) is derived assuming the average linear spectrum breaks around 4 MeV (*McNeehan-Brown et al. 1990*) to a power law with an index of $\alpha = -1.7$. The thick solid line indicates the sum of all the components.

Why all this non thermal equilibrium radiation?

Gamma, diffuse emission

Emission due to:

- the interactions of cosmic electrons with:
 - the magnetic fields (**synchrotron radiation** dominates the radio emission of the Galaxy up to a few GHz)
 - interstellar Matter (ISM); **bremsstrahlung** important below 100 MeV
 - Interstellar photon: **Inverse Compton** above GeV
- the **decay of π^0** produced when CR interact with protons and nuclei
 - $\pi^0 \rightarrow \gamma\gamma$ above 100 MeV
 - Concomitant emission of ν in the decay of π^\pm

Gamma, diffuse emission

408 MHz

100 MeV

Galactic or Extragalactic CR ?

Definite answer from EGRET in 1993 !

Hypothesis: if CR are extra or metagalactic, the density of CR is identical in our Galaxy and in its satellites

- Radio observations radio give the mass of gas M_H in the SMC
- M_H implies a measurable flux for SMC of: $2.5 \times 10^{-7} \text{ cm}^{-2} \cdot \text{s}^{-1}$
 $F_\gamma \propto M_H N_{CR} R_q$
- EGRET gives an upper limit (at 95%CL): $< 0.5 \times 10^{-7} \text{ cm}^{-2} \cdot \text{s}^{-1}$
- The CR density is 5 times smaller within SMC

Cosmic rays are indeed Galactic !

The general problematic

- Thermal speeds \rightarrow RCUHE (few 10^{20} eV)

Produce them

- From top to bottom (decay...)
- From bottom to top (acceleration)

Preserve them

- Energy losses (Synch., IC, π , pairs...)
- Destruction (photo-dissociation...)
- Escape probabilities

Propagate them

- Propagation in ISM and IGM (mag fields: deflection, confinement...)
- Re-acceleration

Detect them

- Balloons, satellites...
- Air showers...
 - Cherenkov telescopes
 - Surface & Fluorescence Detectors

Propagation medium,
IGM, ISM and
atmosphere

Dimensions of the Milky Way

$1 \text{ pc} \approx 3 \text{ l.y.} \approx 3 \times 10^{16} \text{ m}$

Milky Way, a spiral galaxy

Milky Way, a spiral galaxy

Local spur and neighboring arms
 ⇒ local matter and B field inhomogeneity.

Mean "regular" B field
 ~ 3 μG roughly parallel to spiral arms, more intense in between arms.

Milky Way, a spiral galaxy

Local spur and neighboring arms
 ⇒ local matter and B field inhomogeneity.

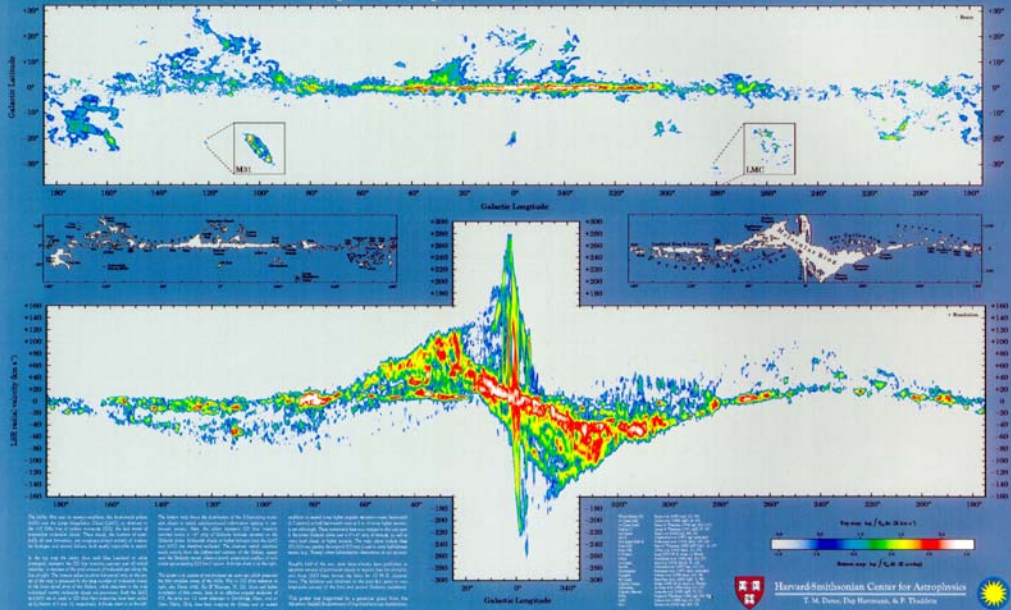

Mean "regular" B field
 ~ 3 μG roughly parallel to spiral arms, more intense in between arms.

Measured from Faraday rotation of the polarized emission and dispersion measurements on pulses from radio pulsars.

A thick target...

The Milky Way in Molecular Clouds

A thick target

- Diffuse gamma-ray emission from galactic CR interaction with matter (mostly molecular H clouds).

2016

F. Montanet - Astroparticle physics ESPAP

54

The nearby islands...

Andromeda (M31)
A twin of our Milky Way slightly larger and (only) distant by 780kpc.
Many small (dwarf) galaxies are orbiting around these twins.

The local group and the Virgo cluster

Our local group is at the periphery of the large Virgo supercluster (~2000 galaxies) at ~20Mpc

2016

F. Montanet - Astroparticle physics ESPAP

Another super cluster: Abel 1689

2016 F. Monnet - Astroparticule physique ESPAP

A 300Mpc horizon

2016 F. Monnet - Astroparticule physique ESPAP

The "GZK" sphere

Large scale filamentary structures

2016 F. Monnet - Astroparticule physique ESPAP

Vacuum is not emptiness !

- Inter Galactic Medium contains:
 - Magnetic fields (regular + random) are highly speculative and range from $2 \cdot 10^{-6}$ nT (20pG) to 10^{-4} nT (1nG).
 - Very little matter (p, He, and a few electrons): ≤ 1 proton / m^3
 - Electromagnetic radiations:
 - 413 CMB photons per cm^3
 - Also IR, radio photons...
 - Neutrinos:
 - Mostly $C\nu B$ neutrinos (decoupled when universe was only 2" old!)
 - Today 1.95°K i.e. $1.7 \cdot 10^{-3}$ eV
 - 336 ν (all species) per cm^3
- + Many mysterious dark matter WIMPs ...

2016 F. Monnet - Astroparticule physique ESPAP

The earth atmosphere

- An evident characteristic of the atmospheric medium is that of being inhomogeneous.
 - Its density, diminishes six orders of magnitude when the altitude above sea level passes from zero to 100km, and another additional six orders for the range 100km to 300km.
 - Although up to ~100km, the composition is nearly constant: 78.47% N, 21.05% O, 0.47% Ar and 0.03% other elements.
 - It follows a quasi exponential profile ("quasi" because T is not quite constant!)

$$\rho(h) = \rho_0 e^{-gMh/RT}$$

The earth atmosphere

Figure 2.3. Density of the air as a function of the vertical altitude. The dots represent the US standard atmosphere data [14], while the full green line corresponds to Linsley's model [16] and the dashed red one to the isothermal atmosphere $\rho(h) = \rho_0 e^{-gMh/RT}$ with $\rho_0 = 1.225 \text{ kg/m}^3$, $M = 28.966$ and $T = 288 \text{ K}$.

$$\rho(h) = \rho_0 e^{-gMh/RT}$$

Scale height $gM/RT \approx 9 \text{ km}$

The earth atmosphere

Figure 2.4. Vertical atmospheric depth, X_v , versus vertical altitude over sea level, h , accordingly with Linsley's model [16].

The earth atmosphere

- In terms of particle/radiation interaction with matter, the atmosphere is:
 - A total of $\approx 1000 \text{ g/cm}^2$ at sea level
 - So 1 atm ~ 12 interaction lengths ($\lambda_N \approx 85 \text{ g/cm}^2$)
 - A vertical proton first interacts at $h \sim 15 \text{ km}$
 - One radiation length (at 1 atm) $X_0 = 36.6 \text{ g/cm}^2 \approx 300 \text{ m}$
 - One Moliere radius (at 1 atm) is $\rho_M \approx 78 \text{ m}$
 - The Lorentz factor for a muon produced at $h = 10 \text{ km}$ to reach ground before decaying is $\Gamma > 15$ ($> 1.6 \text{ GeV}$)
 - Critical energy (EM) $E_c = 84,2 \text{ MeV}$

Interaction and radiation lengths in atmosphere

65

Shower development

Physics well out of reach of colliders !

At each step energy is shared by more numerous particles

"Hadronique" shower

"Electro-Magnétique" shower

$\lambda_{interaction} < \beta \gamma c \tau_{decay}$

$\lambda_{radiation} < \lambda_{ionisation}$

Maximum of développement

Critical Energy E_c

No more multiplication, decrease by decay and energy loss

$\lambda_{interaction} > \beta \gamma c \tau_{decay}$

$\lambda_{radiation} > \lambda_{ionisation}$

At ground, essentially $\mu^\pm \gamma e^\pm$

Time structure

Astrophysical Sources Cosmic Accelerators

General ideas on acceleration

- Take the necessary energy somewhere...
 - Kinetic energy:
 - Translation: shock waves, moving clouds...
→ Fermi acceleration
 - Rotation : pulsars, black holes, neutron stars
 - Gravitational energy
 - via accretion (→ jets...): accretion disks (divers)
 - Electromagnetic (EM)
 - From turbulence, from compression, or from rotating magnets...
- In fine, charged particles interact with EM fields: $f = q (E + v \times B)$
- Remember: Astrophysical shocks are collisionless.
→ Energy transfert through EM fields !

E and B fields in Universe

- * In ISM as on earth, $\langle E \rangle \approx 0$
 - ISM is neutral or conducting
- * Transient electric fields:
 - Magnetic re-connections (e.g. solar flares...)
 - EM waves
- * Producing E fields in EM "engines"
 - Astrophysical dynamos, induction machines
- * Magnetic fields :
 - $\epsilon_B \approx 1\text{eV}/\text{cm}^3 \approx \epsilon_{\text{optique}} \approx \epsilon_{\text{CMB}} \approx \epsilon_{\text{CR}} !!!$
 - Astrophysical plasmas :
ISM, stars, accretion disks, IGM, jets, etc...

Magnetic field production

- Large scale movements of ionized media
→ generating magnetic fields, magnetized clouds...
- Turbulence in interstellar medium
→ Magnetic turbulence, inhomogeneous B fields, plasma waves...
- Hydro and MHD instabilities
 - e.g. Rayleigh-Taylor in supernova remnants
- "Streaming" instabilities
 - CR generates waves in a magneto-active plasma
→ creating the conditions for their own diffusion

Magnetic field production

In many cases, **equipartition** can be reached

- for ex: behind a shock wave :
thermal en. \sim kinetic en. \sim magnetic en.

\Rightarrow Energy exchange between macroscopic structures and individual particles

\Rightarrow individual particles may reach very high energies!

Magnetic fields and acceleration !

• How is it possible at all?

magnetic fields don't work ! ($\vec{F} \perp \vec{B}$)

• Well, variable $\vec{B}(t)$ fields do ! (example: *Betatron*)

$$\vec{\nabla} \times \vec{E} = -\frac{\partial \vec{B}}{\partial t}$$

• In a different reference frame, a pur \vec{B} field is feeled as a \vec{E} field...

$$\vec{E}' = \vec{v} \times \vec{B} \text{ (for } v \ll c\text{)}$$

• In principle, one can always identified an effective \vec{E} field that works, but the description in terms of \vec{B} fields is often simpler (and more physical !)

\rightarrow Acceleration by "change of reference frame"

Principle of Fermi acceleration

The Ingredients :

- **A magnetic field \vec{B}**
= with a regular component \vec{B}_0
+ and irregular component $\delta\vec{B}$
- **A plasma** i.e. a good electrical conductor :
 $\vec{E} + \vec{u} \times \vec{B} = 0$ and $|E| \approx 0$
 \Rightarrow the magnetic field is "frozen" and moves with the plasma (Alfven).
- **A CR population** coupled to the medium via the magnetic field \vec{B} . They scatter on the field irregularities. This diffusion processes are **collisionless** i.e. they conserve the particle energy. The MHD or Alfven waves act as massive scattering centers (recoilless).

Fermi 1949 :

- first hypothesis of converging movements of MHD perturbations
 \Rightarrow "first order" acceleration, but where ?
- second more realistic hypothesis at that time: random mouvement of interstellar gas clouds (observed) or MHD perturbations
 \Rightarrow "second order acceleration.

Where to accelerate

• **At creation :**

- For example: e^- extracted from the surface of a neutron star by an intense E field.

• **Within the source neighborhood :**

- For example: Fermi acceleration in plasma shocks in a SNR.

• **During transport:**

- "reacceleration" by shock waves and excitation of Alfven waves during diffusive transport in the Galaxy.

Power laws and stochastic processes

- The power laws observed in differential energy spectra follow naturally from cyclic acceleration mechanisms with constant energy gain and constant escape probabilities:

- Initial energy: E_0
- Energy gain at each cycle: $\Delta E = \varepsilon E$
- Particle energy after n iterations: $E_n = E_0(1 + \varepsilon)^n$
- Escape probability from the acceleration zone: P_{esc}
- Probability to remain in the acceleration zone: $(1 - P_{esc})^n$

A small analogy...

- A tennis ball bouncing on a wall
 - neither gain nor loss of energy...

bounce = speed unchanged

Same thing with a motionless racquet...

Then how does one accelerate a tennis ball ?!

Power laws and stochastic processes

- Particle energy after n iterations: $E_n = E_0(1 + \varepsilon)^n$
- Probability to remain in the acceleration zone: $(1 - P_{esc})^n$

Number of iterations to reach an energy E :

$$n = \frac{\ln(E/E_0)}{\ln(1 + \varepsilon)}$$

Proportion of particles accelerated up to an energy equal or greater than E :

$$N(\geq E) = N_0 \sum_{m=n}^{\infty} (1 - P_{esc})^m = N_0 \frac{(1 - P_{esc})^n}{P_{esc}}$$

thus :
$$\frac{\ln(P_{esc}N/N_0)}{\ln(1 - P_{esc})} = n = \frac{\ln(E/E_0)}{\ln(1 + \varepsilon)}$$

eliminating n :

$$N(\geq E) \propto \left(\frac{E}{E_0}\right)^{-\gamma}$$

with $\gamma = \frac{-\ln(1 - P_{esc})}{\ln(1 + \varepsilon)} \approx \frac{P_{esc}}{\varepsilon} = \frac{1 T_{cycle}}{\varepsilon T_{esc}}$

Power laws are natural !

- Moving racquet

- Neither gain nor loss of energy... in the racquet reference frame !

Speed unchanged with respect to the racquet

→ acceleration through a change of reference frame

- A drop shot:

Particle deceleration !

81

Fermi Acceleration

- Ball \rightarrow charged particle
- Racquet \rightarrow "magnetic mirrors"

Magnetized clouds ($M \gg m_p$), with a typical speed wrt ISM $\sim 10\text{km/s}$

- Magnetic inhomogeneities or plasma waves also work...

82

The essence of stochastic de Fermi acceleration

- 1 When a particle bounces on an **incoming** magnetic mirror, in a **head-on** collision, it **gains** energy.
- 2 When a particle bounces on a **receding** magnetic mirror that it catches back, it **loses** energy.
- 3 Head-on collisions are **more frequent** than receding collisions.

\Rightarrow Net energy gain in average (stochastic process)

83

Add a second player...

- Converging flows...

84

Shocks hydrodynamics

- Shock waves (e.g. supernova explosion) : expending plasma flow with a speed V_R much larger than the sound speed in the interstellar medium (ISM).

Shocks hydrodynamics

- Shock wave:

- The shock moves at a speed V_S which depends on V_R and the specific heat of both media.
- For an ionized ISM: $V_S \approx \frac{4}{3}V_R$

Shocks hydrodynamics

- Onde de choc :

- The shock intensity is characterized by the compression factor:

$$R = \frac{V_S/V_R}{V_S/V_R - 1} \approx 4$$

Shocks hydrodynamics

In the shock frame

- In the shock frame, the upstream (non-shocked) medium flows toward the shock at a speed V_S and the downstream (shocked) medium flows away with a speed reduced by the compression factor (mass flow conservation) :

$$V_S/V_d = R \approx 4$$

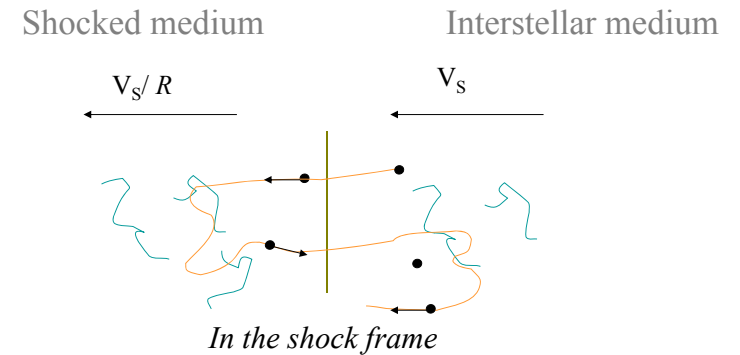

Shock wave diffusive acceleration

- Shock wave (e.g. supernova explosion)

- Magnetic wave generation:**
 - Downstream:** by the shock (compression, turbulence, hydro and MHD instabilities, shear, etc.)
 - Upstream:** by the accelerated cosmic rays themselves!
- 'isotropization' of the distribution (in the local frame)

A win-win process !

- At each shock crossing, one way or the other, the particle hits a "magnetic wall" with a relative speed:

$$V = (1 - 1/R)V_s$$
 → only head-on collisions...

Summary on acceleration

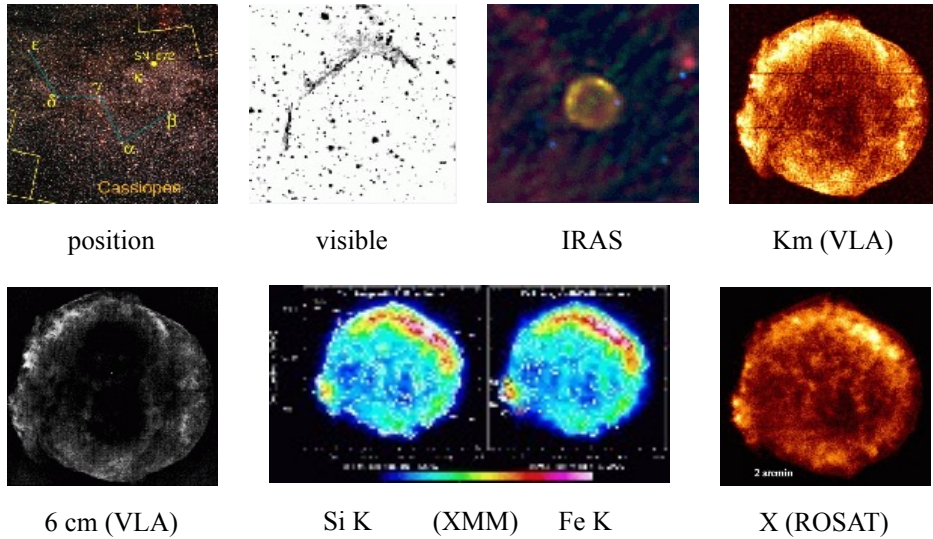

- Acceleration from interaction with fields**
 - E field:** e.g. induced by spinning magnets such as neutron stars (pulsars) or black holes...
 - B field:** inhomogeneous moving fields
 - MHD waves**
- Acceleration by reference frame transformation**
 - Fermi stochastic acceleration (2nd order)
 - Diffusive shock acceleration diffusive (1st order)
- Power law are natural**
 - Fermi type process ($\Delta E \propto E, P_{ech}$)
 - Universal power law for non relativistic shocks ($N(E) \propto E^{-2}$)
- Cosmic rays up to the knee**
 - CR power = power of SNe, $E_{max} \approx 10^{14} \text{ eV}$ hardly 10^{15} eV

The CR standard model

- Analytic calculations, simulations and observations show that diffusive shock acceleration works !
- Supernovae and GCRs
 - Estimated efficiency of shock acceleration :... **10 – 50%**
 - Power required to sustain CR energy density: $\epsilon_{CR} \times V_{conf} / \tau_{conf} \sim 10^{41} \text{ erg/s !}$
 - Power injected by SN power in the Galaxy: **10^{42} erg/s !**

→ Enough power for Galactic CR

Tycho, 11 November 1572...

The CR standard model

- Proposed acceleration site, **isolated SNR**
 - Supernovæ : ejection of many solar masses of nuclear matter at supersonic speeds ($\sim 10\,000$ km/s) following massive star explosion.
 - Formation of a quasi spherical expanding shock wave that wipes out the interstellar medium (ionized beforehand by the progenitor's radiation).
 - Total kinetic energy injected by the explosion: 10^{51} erg (= 10^{44} J).
 - Roughly 3 SNe per century within our Galaxy, which corresponds to an averaged power of 10^{42} erg/s (10^{35} W)
 - SNR are observed at all wavelengths.
 - SNe explosion is essential to the Galaxy chemical content: heavy elements enrichment.

The CR standard model

- Shock waves in isolated SNe (SNR)
 - Source composition source \sim interstellar medium + modifications (ionizability, volatility, Z/A effects, ^{22}Ne ...)
 - Source spectrum: E^{-2} power law
 - Maximal energy reached: $E_{\text{max}} \sim 10^{15}$ eV
- Energetics :
 - Measured flux / speed = CR density
 - CR density \times mean energy = energy density
 - Energy density \times confinement volume = total energy
 - Total energy / confinement time = necessary injected power
 - $P_{\text{CR}} \sim 1.5 \times 10^{41}$ erg/s
- Required efficiency $\sim 10\text{-}30\%$...

Finite size

Finite size of confinement magnetic field
 \updownarrow
 Larmor radius

$$r_g \leq R$$

$$\Leftrightarrow \frac{p}{ZeB} \leq R$$

$$\Leftrightarrow E \leq Ze \times B \times R$$

$$\Leftrightarrow E \leq (10^{17} \text{ eV}) Z B_{\mu G} R_{pc}$$

log(R/km)

CR SM with $E_{max} \propto Z$

Hard to explain a single power law above the knee. Need probably another component up to 10^{17} eV
 See for ex : M. Hillas
 J. Phys.: Conf. Ser. 47 (2006) 168
 (<http://iopscience.iop.org/1742-6596/47/1/021>)

The knee

- Is the knee simply the consequence of an energy cut-off of accelerators (SNR) or is it due to :
 - a propagation effect ?
 - different CR sources ?
 - a physics threshold at $\sim E_{LHC}$?

⇒ The CR SM implies a change in composition at the knee energy.

SNR energy limit : $E_{max} \sim Z \cdot 10^{15}$ eV

- Data:
- Proton4 sat
 - Akeno
 - Yakutsk
 - Haverah Pk

Explaining the ankle is much easier...

- Two components with two different slopes...

- For exemple, galactic and extragalactic...

DIFFUSE GAMMA-RAY SOURCE

VHE gamma-rays sources

γ-rays production processes:

- Electro-Magnetic processes :

- Bremsstrahlung
- Synchrotron radiation
- Inverse Compton

- Hadronics processes:

Hadronic production of gamma-rays

Source function [TK Gaisser]

$$q_k(E_k, r) = \int \frac{d\sigma_{i \rightarrow k}(E_k, E_i)}{dE_k} \left(\frac{c\rho(r)}{m} \right) \left(\frac{4\pi}{c} \phi(E_i) \right) dE_i$$

Fluxes on earth (neutrals)

$$\phi_{k=\gamma} = \frac{dN_k}{dAdE_k d\Omega} = \int \frac{q_k(E_k, r)}{4\pi r^2} d^3r = \int_0^{r_{max}} \frac{q_k(E_k, r)}{4\pi} dr d\Omega$$

Scale invariance : $E_\gamma/E_i = Z$ (Z indep. of E)
 (for $E_k \gg m_i/2 = m_\pi/2 \approx 70 MeV$)
 (system mass scale).

$$\left. \begin{array}{l} \text{Scale invariance} \\ \text{(for } E_k \gg m_i/2 = m_\pi/2 \approx 70 MeV) \\ \text{(system mass scale).} \end{array} \right\} \Rightarrow \phi_k \propto \phi_i$$

Parent spectral density power law $\phi_i \propto E_i^{-\alpha}$
 [Gaisser, Halse, Berezhinsky, Stanev]

$$\phi_\gamma = 4\pi\rho \left[\frac{\sigma_{inel}}{m_N} \right] \left[\frac{2Z_{N \rightarrow \pi^0 \rightarrow \gamma}}{\alpha} \right] \phi_{CR}(E)$$

$$\frac{\phi_\gamma}{\phi_{CR}} \approx 6 \times 10^{-4} \times \left(\frac{\rho R}{[g.cm^{-2}]} \right) \rho R = \text{target column density}$$

Bremsstrahlung

$$\frac{d\sigma_{e \rightarrow \gamma}(E_\gamma, E_e)}{dE_\gamma} = \frac{1}{E_e N_A X_0} \phi(z)$$

where $\phi(z)$ is a function of $z = E_\gamma/E_e$

For energies $> 70 MeV/c^2$, there is a scaling relation between the γ energy and that of the parent electron. (the only mass scale in the problem is the electron mass, much lower than 70 MeV).

\Rightarrow the differential spectrum of the progenitor electrons ($\phi_e(E_e) \propto E_e^{-\alpha}$) is transmitted to the γ differential spectrum:

$$\phi_\gamma(E_\gamma) \propto E_\gamma^{-\alpha}$$

For $dN/dE_e = a_e E_e^{-\alpha}$ and $\alpha = 2.7$

$$q_{br} \approx 1.2 \times 10^{-25} a_e n E_\gamma^{-2.7} \text{ photons GeV}^{-1} \text{ s}^{-1} \text{ cm}^{-3}$$

VHE Gamma sources

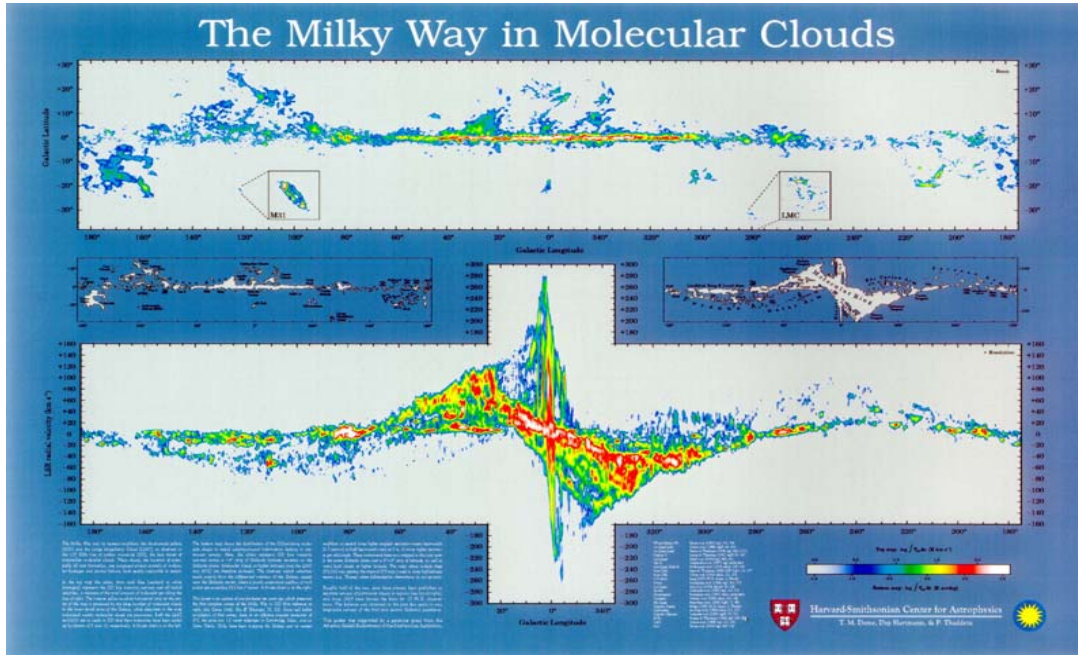

- Productions of $\gamma > 10 MeV$
- Synchrotron radiation negligible.
- Inverse Compton

For $\phi_e \propto E^{-\alpha}$
 the IC spectrum is much flatter
 $\propto E^{-(\alpha+1)/2}$

but $N_e \ll N_p$ and the electron spectrum drops \searrow above a few GeV (synchrotron radiation energy losses)

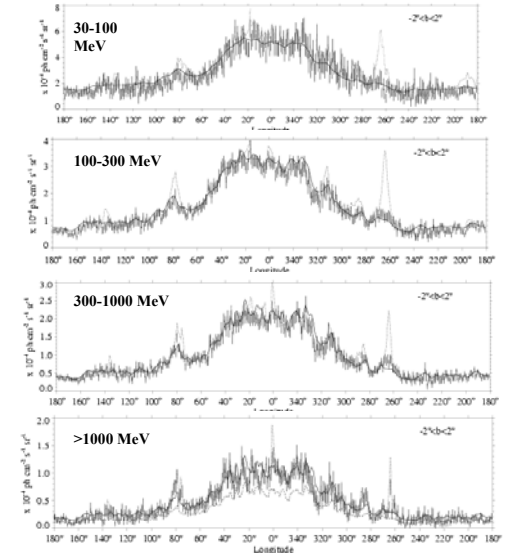

The target...

Tracking back the CR flux elsewhere in the Galaxy

- Knowing the target column density from radio 21cm measurements and fitting the diffuse γ flux, one can map the density, spectrum and composition of CR elsewhere in the galaxy.

- S.D.Hunter et al, ApJ 481 (1997) 205
- M.Pohl and J.A.Esposito ApJ, 507 (1998) 327
- S.LeBohec et al, astro-ph/0003265
- Strong, A.W., Moskalenko, I.V., ApJ 509:213-228, 1998

Tracking back the CR flux elsewhere in the Galaxy

- Other constrains
 - Protons local spectrum and flux (altered <10GeV solar magnetic field)
 - Electrons local spectrum and flux (influenced by the local bubble of matter under-density)
 - Radio measurements of the synchrotron emission

Tracking back the CR flux elsewhere in the Galaxy

- Refined predictions based on detailed simulations (magnetic model of the galaxy, CR diffusion equation, matter density maps...):
for ex: GALPROP program

COMPACT OBJECT ENVIRONMENT : NEUTRON STARS AND PULSARS BLACK HOLES

109

Neutron stars, Pulsars

Journey into the
Crab nebula.

Here is radio pulsar...

PSR0329+54
~1,40 Hz

Vela
PSR0833-45
~11Hz

Crabe
PSR0531+21
~30 Hz

PSR1937+21
~641 Hz

Neutron stars

- Ultra compact objects:
 - Density ~ nuclear matter ($10^{13} \times$ water !)
 - sphere ~ 10 km radius
 - gravitation at surface ~ $5 \times 10^{10} \times$ gravitation on earth
- Density and structure varies with :

- Iron core (0,3km)
- Neutrons and Nuclei (0,6km)
- Neutrons forming an superfluid ocean (8km)
- Unknown (1km)

Magnetic field of a neutron star

- Most celestial bodies bear a magnetic field (i.e. the sun: 10^{-3} Tesla)
- At the surface of a neutron star, it is ≈ 10 million Tesla
- This value is intrinsically linked to the rapid rotation (conservation of rotation kinetic energy and magnetic energy \rightarrow concentration)
- A kind of giant **COSMIC DYNAMO** : rotation of $\vec{B} \Rightarrow \vec{E} \Rightarrow 10^{18}V$!!
- The electric force at the surface is \gg gravitational force !
 \rightarrow charged particles are **expelled** and **accelerated**
 $\Rightarrow 10^{38} e^-$ per second radiating synchrotron light.
- The strong anisotropy of the radiation is badly understood but probably due to the intense \vec{E} and \vec{B} fields near the "polar caps".

- Two distinct components

Preliminary evaluation from CELESTE data of the Crab Nebula around 60 GeV

VHE photons sources

- γ -ray production:
 - Electro-magnetic processes :

- Bremsstrahlung

- Synchrotron radiation

- Inverse Compton scattering

- Hadronic processes :

The Crab Nebula a case study for VHE gamma-rays VHE

- TeV emission is based on **Inverse Compton** scattering
- The e^- producing **synchrotron radiation** can interact with these synchrotron photons.
- If $\lambda_{\text{target photon}} \ll \lambda_{\text{compton}} = \frac{h}{m_e c}$ it is possible to transfer most of the incident e^- energy to the photon.
ex: A $10^{13} \text{ eV } e^-$ can boost an I.R. photon I.R. into a VHE gamma-ray.
- These "Self Synchrotron Compton" models reproduce both GeV and TeV spectra.

The Crab Nebula a case study for VHE gamma-rays

Model SSC : Synchrotron Self Compton

PWN emission mechanisms: the Crab Nebula

Many recently discovered sources in the Galactic plan by HESS, MAGIC and VERITAS large angle surveys

ApJ 636, 777 (2006)

Galactic Longitude (°)

THE ENVIRONMENT OF SUPERMASSIVE BLACK HOLES: ACTIVE GALACTIC NUCLEI

AGN: a unified scheme

Active Galactic Nuclei

- Galaxies with an important activity of its nucleus
- Numerous classes of objects:
 - Radio-galaxies
 - Radio-quasars
 - BL Lac objects
 - Violently Variables objects (VVO)
 - Radio Quiet Quasars
 - Seyfert Galaxies of type 1
 - Seyfert Galaxies of type 2
 - Low Ionization Nuclear Emission-Line Regions (LINERs)
 - Nuclear HII Regions
 - "Star Burst" Galaxies
- Arbitrary categories et badly mal defined.

What is an AGN

• Elementary AGN model:

Discovered in the early 60ties when trying to identify the sources in the 3rd Cambridge Catalogue.

- Superluminous objects
 - Spectral redshift → cosmological distances
 - For 3C273 → $P \approx 10^{40}$ Watts ≈ 10000 the Milky Way ≈ 1000 SN/year
- Very small objects
 - Variability criteria → $d \approx$ solar system size !!

What is an AGN

• Elementary AGN model:

Discovered in the early 60ties when trying to identify the sources in the 3rd Cambridge Catalogue.

- Objects from the past
 - The most distance quasars observed ($z \approx 5$) are at distances of the order of the radius of the **observable universe!**
 - No such objects in our close environment → must be linked to a phase of the galaxy evolution.

The Quasar 3C 273

In 1963, 3C 273, the first quasar, was discovered. They can be up to **1000 more luminous** than the massive host galaxy. The emission originates in the **active nucleus** of the galaxy.

What is an AGN

• Necessarily a gravitational engine

Thermonuclear falls short by a factor 10 to 100 !

Form of energy release	Efficiency of energy production (wrt mc^2)
• Chemical energy	10^{-9}
• Nuclear energy	10^{-2}
• Accretion of mass onto non-rotating black holes	6×10^{-2}
• Accretion onto maximally rotating Kerr black holes	0.42
• Rotational energy of maximally rotating Kerr black holes	0.29

What is an AGN

- Necessarily a gravitational engine

$$E_{tot} = 0 \Rightarrow E_{cin} = \frac{GmM}{R} \Rightarrow R \text{ must be small}$$

Huge mass, small volume \Rightarrow BLACK HOLE !!!

$$\text{With } R_S = \frac{2GM}{c^2} \Rightarrow E_{rad.max} \approx \frac{GM R_S}{R_S R} m = \frac{1 R_S}{2 R} mc^2$$

Accounting for relativistic corrections and ergosphere rotation
 \rightarrow conversion efficiency $m \rightarrow E$ few 10%

133

What is an AGN

- Necessarily a gravitational engine

One gets 10^{40} Watts with $15M_{\odot}$ /year.

Over 10^8 years (age measured from radio lobes) $\Rightarrow 10^9 M_{\odot}$
 $\Rightarrow R_S \approx 10^{13} m$ compatible with variability.

More over, one is below **Eddington** luminosity
(radiation pressure = gravitational forces)

$$\left(L \approx \frac{4\pi c}{\sigma_T} GMm_H \right) \text{ de } \left(\frac{\sigma_T L}{4\pi R^2} = \frac{GMm_H}{R^2} \right)$$

\Rightarrow PLAUSIBLE.

134

What is an AGN

- Accretion of matter:

- In absence of angular momentum:

$$\vec{v}_{\infty} \text{ directed toward the BH: } \frac{GMm_H}{R} = kT$$

\Rightarrow almost all is radiated in X or γ rays

INCOMPATIBLE with MEASUREMENTS

- With angular momentum:

Intense radiation in the UV : OBSERVED

\Rightarrow **Anisotropic Accretion**

in the shape of an ACCRESTION DISK

135

What is an AGN

- Jets:

Relativistic particles constituting the jets are accelerated when reflecting on the boundaries of a magnetic "tunnel" induced by the rotating plasmas near the BH.

- Hot spots

Terminal shocks (jet-IGM): large size moderate field regions
 \Rightarrow plausible place for UHECR production.

\rightarrow explains many observed phenomena with both leptonic and hadronic models.

136

What is an AGN

• Jets:

Formation of extragalactic jets from black hole accretion disk

Cygnus A

The Radio Galaxy Cygnus A

Cygnus A - X-ray image

FERMI 2nd LAC catalogue

886 AGN with a clear GeV gamma-ray signal, identified with comprising 395 BL Lacertae objects (BL Lac objects), 310 flat-spectrum radio quasars (FSRQs), 157 candidate blazars of unknown type (i.e., with broadband blazar characteristics but with no optical spectral measurement yet), 8 misaligned AGNs, 4 narrow-line Seyfert 1 (NLS1s), 10 AGNs of other types, and 2 starburst galaxies

EGRET

- Before EGRET : 3C273
- After EGRET : 33 AGN a more than 5σ all Blazars

Third EGRET Catalog
 $E > 100$ MeV

EGRET

- AGN basic results :
 - The γ -ray energy flux is often dominant
 - A naive estimate $(4\pi d^2 L) \approx 10^{47} \rightarrow 10^{49} \text{ ergs.s}^{-1}$
 - $0,03 \leq z \leq 2,28$
 - $(30 \text{ MeV} - 30 \text{ GeV})$ spectrum \sim a power law:
 $\frac{dN}{dE} \propto e^{-\alpha}$ with $1,3 \leq \alpha \leq 3,0$
 - Many sources are strongly and rapidly variables on time scales ~ 1 month.
 - Many known AGN are not detected in γ -rays.

EGRET

Variability:

- Most EGRET Blazars are variable on time scales \sim days or months.

Source	T_{var} (jours)	T_{var} AGN (jours)
0208-512	8	4
0235+164	<90	<46
0446+112	15	...
0528+134	2	0,65
1253-55	2	1,3
1406-076	6	2,4
1633+382	2	0,7
2251+158	4	2,2

- Short time scales are **constraining the source size**:
1 day \Rightarrow Scharzchild radius of a $10^{10} M_{\odot}$ black hole.

Third EGRET Catalog

$E > 100$ MeV

Non identified sources
Blazars (AGN)

7 Pulsars
LMC

5 Supernova remnants

Sources seen from the ground

$E > 250$ GeV

After COS-B, the great success of EGRET has been the rather unexpected discovery that ≈ 100 blazars are brilliant in the GeV energy range *with no turn-over at maximum energies*

During about the same decade the TeV observations broke through, with no pre-notice. The a posteriori surprise is the scarcity of sources

- the intermediate region, from 30 to 300 GeV, remains unexplored
- the (few) TeV blazars are weak EGRET sources
- the absorption ($\gamma\gamma \rightarrow e^+e^-$) obscures the far Universe for TeV γ 's

Mrk 501 flares of April 1997 showing variability on a day scale

Even faster (<hr) variations have been evidenced by the Whipple on Mrk 421

FERMI (launched 16/5/2008)

The Gamma ray bursts Coordinates Network

GRB's

- **Gamma-Ray Bursts : intense gamma-ray flux**
 - 0.1 to 1 MeV, and up to 100 MeV
 - Emitted on a short time scale (~ 1 second !)
 - Observed ~once per day, with an isotropic distribution
 - Source at cosmological distances (most distant is $z = 9.4$!!)
- **γ -ray luminosity: $\sim 10^{52}$ erg/s ($10 \times$ SNe !)**
- **Extreme variability in intensity and spectrum**
 - Time scales from 10 ms to 10 s
 - Some very short 1 ms variabilities \rightarrow internal shocks
- **Clear bimodality suggesting the existence of two separate populations:**
 - a "short" population with an average duration of about 0.3 seconds
 - a "long" population with an average duration of about 30 seconds.

169

UHE SOURCES

General limits on models

Shock waves

- **Acceleration site confinement: $r_g = E/Z\beta c < L$**
 - Depends in fact on $V_{shock} = \beta c$:

$$E_{max} \approx \beta \times Ze \times Bc \times L$$

Unipolar induction

- **Accelerate in one step (E field, $f_{Lorentz} \approx V_{rot} \times B \times R$)**
 - \rightarrow No confinement necessary

Top-Down Models

- **No acceleration at all !**
 - Decay products of exotic physics states, supermassive particles at E_{GUT} , Topological Defects...

171

Bottom-Up

ZeVatrons

Astrophysical Accelerators reaching ZeV

Acceleration = Fermi-like diffuse acceleration.

Frist challenge, E_{max} : Reach $\geq 10^{20}$ eV

(if 1 TeV is hard, guess for 10^9 TeV !!)

Second challenge, Propagation : B_{igm}

(determine the spectrum and the arrival)

Hillas criterion:

Magnetic confinement in the shock zone i.e.

$1 R_{gyr} < \text{accelerator size}$

Not many candidates survive!

Neutron stars (pulsars)

AGNs

Radio lobes

Clusters

Colliding Galaxies/Clusters

Gamma Ray Bursts

172

Hillas diagram

Standard estimates for E_{max} :

- Confinement :
 $r_g = E/(ZeB) < R \Rightarrow E < ZeBR$
- Unipolar inductor (pulsar)
 $E < ZeBR(\Omega R/c) \approx \beta_s ZeBR$
- Diffusive acceleration by non relativistic shocks:
 $\tau_{acc} \approx 10\kappa/u_s^2 < R/u_s$ avec $\kappa > r_g c$
 $\Rightarrow E < \beta_s ZeBR$
- Diffusive acceleration by relativistic shocks:
 $E < \Gamma_s ZeBR$
- General Hillas condition:
 $E < 0.9\beta\Gamma ZeB_{Gauss} R_{pc} ZeV$

Relativistic shocks

- Acceleration $\propto \Gamma^2$ works fine for a couple of cycle
- After that it fails for mere kinematical reasons
- But this is still very efficient (\gg standard shocks)
- Confinement is easier

A weak deflexion is enough : $\delta\theta \approx 1/\Gamma_s \Rightarrow r_g < R_s/\Gamma_s$
 $\Rightarrow E_{max} \approx \Gamma_s \times$ larger
 \Rightarrow one can reach the limits induced by energy losses

BOTTOM -UP

Galactic pulsars
 Extragalactic radio galaxy lobes

Fermi acceleration and UHE neutrino production

COSMOLOGICAL SOURCES

"Cosmogenic" or "GZK" Neutrinos

- Produced by the propagation of UHECR in the IGM.
- Main assumptions:
 - UHECR are protons or nuclei (makes a big difference)
 - The sources distribution is following a given redshift distribution
 - Spectra are known and flux are generic
 - The target density is well known (CMB photons)
- This flux can be predicted in a relatively robust manner.

Cosmogenic or "GZK" Neutrinos

Flux attendus

I + II + III →
 $\nu_\mu : \nu_e : \nu_\tau = 2:1:0$ (source)
 oscillations
 $1:1:1$ (earth)

Flux of "GZK" neutrinos

Influence of

- Composition of UHECR,
- Sources distribution and evolution.

Dark Matter as a source of neutrinos

Annihilation in Halo, Earth, Sun or Galactic Centre

Signature	Experiment
Halo Positron, Antiproton Gamma rays $\chi \chi \rightarrow Z \gamma, \gamma \gamma$	BESS, CAPRICE, AMS, .. HESS, GLAST, MILAGRO, ...
Earth, Sun, GC Neutrino $\chi \chi \rightarrow WW, ff$ $W, f \rightarrow \nu X$	SuperK, Baksan, IMB, MACRO AMANDA, ANTARES, Baikal, ...

Gravitational capture of χ in earth, sun galactic centre

WIMP loses energy by elastic interaction
 \Rightarrow if $v < v_{escape}$, capture
 capture + annihilation balance
 \Rightarrow constant density in core

Dark Matter as a source of neutrinos

Energy loss: ionization, Coulombian interactions

Propagated spectra ionization losses only (thick target)

203

Grammage

2016

F.Montanet - Astroparticule physics ESPAP

- Column density or quantity of matter traversed by the CR from its production site to earth (in $\text{kg} \cdot \text{m}^{-2}$ or $\text{g} \cdot \text{cm}^{-2}$)
- Given the diffusion time (known from cosmic clocks see below) the measurement of grammage allows the understanding of the diffusion extension zone.
- The ratio secondary/primary allows estimating the grammage traversed:

$$\frac{dN_S}{dx} = -\frac{\sigma_P}{m} N_P$$

$$\text{donc } N_S = N_P \exp\left(-\frac{\sigma_P}{m} x\right)$$

$$\text{et } x = -\frac{m}{\sigma_P} \log(S/P)$$

$$B/C \approx 35\% \Rightarrow x = -\frac{m}{\sigma_P} \log(B/C) \approx 60 \text{ kg} \cdot \text{m}^{-2}$$

$$\text{if } Br(C + P \rightarrow B + X) \approx 100\%$$

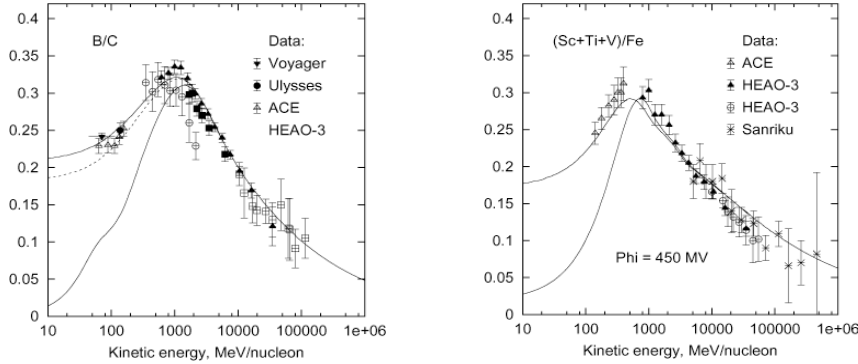

204

Secondary / Primary ratio

The grammage depend on the parent nucleus:

- (Li+Be+B) / (C+N+O) ⇒ mean grammage of 50 kg.m⁻²
- (Sc+Ti+V)/Fe ⇒ mean grammage of 20 kg.m⁻²

and Primary/Secondary ratio (thus grammage) depends on the energy as well:

Secondary / Primary ratio

- A complete CR transport model

– The secondary to primary ratio can be expressed by:

$$\frac{N_S}{\tau_{esc}} + \frac{N_S}{\tau_{spallation}} = \frac{N_P}{\tau_{P \rightarrow S}}$$

$$\Rightarrow \frac{N_S}{\tau_{esc}} + n\beta c\sigma_S N_S = n\beta c\sigma_{P \rightarrow S} N_P$$

$$\frac{N_S}{N_P} = \frac{\sigma_{P \rightarrow S}}{\sigma_S + 1/\lambda_{esc}}$$

with $\lambda_{esc} = n\beta c\tau_{esc}$

Cosmic clocks

Unstable nuclei with lifetimes comparable to the escape time $T_{1/2} \approx \tau^{esc}$ can be used as cosmic clocks.

The ratio unstable/stable isotope helps desantangling density and escape time.

- $^{10}Be \rightarrow \tau = 2.17 Myr$
- $^{26}Al \rightarrow \tau = 1.31 Myr$
- $^{36}Cr \rightarrow \tau = 0.44 Myr$

$$\frac{N_j}{\tau_{esc}} + \frac{N_j}{\tau_{rad}} + \frac{N_j}{\tau_{spallation}} = Q_j + \sum_{k>j} \frac{N_k}{\tau_{k \rightarrow j}}$$

Si $\tau_{rad} \ll \tau_e$ et $\tau_{rad} \ll \tau_{spallation}$:

Measure isotopic ratio $\rightarrow \frac{N_{rad}}{N_{stable}} = \frac{\tau_{rad}}{\tau_{esc}} + \frac{\tau_{rad}}{\tau_{spallation}}$ \rightarrow Estimate escape time.

On gets $\tau_e \approx 20 Myr$

Cosmic clocks and halo size

- Radioactive decay:

$$\frac{N_j}{\tau_{esc}} + \frac{N_j}{\tau_{rad}} + \frac{N_j}{\tau_{spallation}} = Q_j + \sum_{k>j} \frac{N_k}{\tau_{k \rightarrow j}}$$

Measure isotopic ratios \rightarrow

$$\frac{N_{rad}}{N_{stable}} = \frac{\tau_{rad}}{\tau_{esc}} + \frac{\tau_{rad}}{\tau_{spallation}}$$

\rightarrow Estimate escape time

- $^{12}C + H \rightarrow ^9Be$ (stable secondary nucleus)
- $^{12}C + H \rightarrow ^{10}Be$ (unstable secondary nucleus: $\sim 4 \times 10^8$ years)
- The ratio $^{10}Be / ^9Be$ depends on secondaries history (and on cross sections).
 - Link between quantity of matter traversed and diffusion time.

Cosmic clocks and halo size

- $^{12}\text{C} + \text{H} \rightarrow ^9\text{Be}$ (stable secondary nucleus)
- $^{12}\text{C} + \text{H} \rightarrow ^{10}\text{Be}$ (unstable secondary nucleus: $\sim 4 \times 10^8$ years)
- The ratio $^{10}\text{Be} / ^9\text{Be}$ depends on secondaries history (and on cross sections).
 - Link between quantity of matter traversed and diffusion time.
- Diffusion parameters adjustments (excursion in the less dense galactic halo)
 - \Rightarrow determination of the CR confinement zone

Confinement and escape

- The average measured grammage is $x = 50 \text{ kg} \cdot \text{m}^{-2}$
- Associated lengths:

$$\lambda_{esc} = x/\rho \approx 750 \text{ kpc},$$
 with $\rho = 1.4 n_H m_p \approx 2.2 \times 10^{-21} \text{ kg} \cdot \text{m}^{-3}$
- $\lambda_{esc} \gg R = 20 \text{ kpc} \Rightarrow$ CR are confined
- $\lambda_{esc} \ll \lambda_{pp} = (n_H \sigma)^{-1} \approx 6 \text{ Mpc} \Rightarrow$ CR can escape
- Long lived radioactive secondaries (cosmic clocks) indicate $\tau_{esc} \approx 20 \text{ Myr}$
- Average density scanned by CR:

$$n_H = \lambda_{esc}/c \tau_{esc} m_p \approx 0.3 \text{ cm}^{-3} < n_{disk} = 1 \text{ cm}^{-3}$$

\Rightarrow CR diffuse in a thinner region: the Halo

Disk & Halo

- CR can wander out of the disk in a magnetized halo of hot ionized matter

$$T = 10^6 \text{ K} \quad \text{et} \quad n = 10^{-3} \text{ cm}^{-3}$$

- NGC 4631 galaxy and its halo of hot ionized matter emitting X-rays as seen by Chandra

The « leaky box » model

- Diffusive approximation...

$$\frac{\partial N_i}{\partial t} + \frac{\partial}{\partial E} [b(\vec{r}, E) N_i(\vec{r}, E, t)] = Q_i(\vec{r}, E) - \frac{N_i}{\tau_{tot}(\vec{r}, E)} + D(\vec{r}, E) \nabla^2 N_i$$

\uparrow flux in energy space (losses + acceleration)
 \uparrow injection, "in flight" production
 \uparrow destruction, decay, escape
 \uparrow diffusion

- Re-acceleration...

$$+ \frac{1}{2} \frac{\partial^2}{\partial E^2} [c(\vec{r}, E) N_i(\vec{r}, E, t)]$$

Slope of the propagated spectrum

- Escape out of the confinement zone
 - Confinement (escape probability) decrease with E

Without escape
(thick target)

$\tau_{conf} \propto E^{-0.7}$
→ $E^{-2.7}$ spectrum

CR confinement

- Escape depends on E
 - Diffusion on magnetic inhomogeneities
 - When $E \nearrow, r_g \nearrow$ thus interaction with inhomogeneities with larger wavelengths.
- $D(E)$ is an increasing function
 - $D = \beta D_0 \left(\frac{\rho}{\rho_0}\right)^x$ where ρ is the particle rigidity
 - $\tau_{conf}(E) \propto E^{-x}$
- Kolmogorov spectrum → $\tau_{conf}(E) \propto E^{-1/3}$
 - $x - 2 = 1/3 < 0,7$... clearly not enough but...
 - ISM perturbations ? Diffusion-convection, MHD ?
- Determination of $\tau_{conf}(E)$ a posteriori :
 - $2,7 - 2 = 0,7$!!!

The CREAM results

Secondary/Primary ratio

Compatible with propagation models with escape terms in $E^{0.6}$

CR anisotropy

- Very weak observed anisotropy (first angular harmonic)
 - $\delta \sim (0,5 - 1)10^{-3}$ de 10^{12} à 10^{14} eV
 - $\delta \sim 1$ à 2% à 10^{17} eV
 - Upper limit : 5% à 10^{18} eV, 10% à $10^{18,5}$ eV, 30% à 10^{19} eV
- Constraints on $D(E)$
 - In the diffusive approximation, one can compute δ taking into account the position of the solar system wrt the Galaxy.
- Observed anisotropy incompatible with sources distributed like SNR and a diffusion term $D(E) \propto E^{0.6}$ below 10 GeV...
 - ... but compatible with $D(E) \propto E^{1/3}$!

Sources Distribution

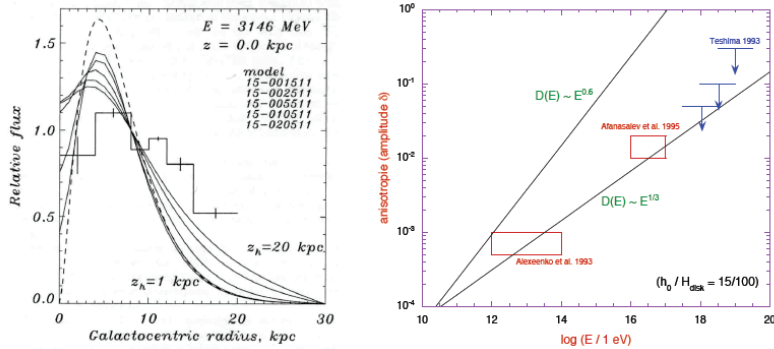

FIG. 5.1 – À gauche : distribution galactocentrique des flux de rayons cosmiques prédits par les modèles de propagations pour différentes tailles du halo de confinement (courbes en trait continu), comparée à la distribution déduite des observations d'EGRET. La courbe en pointillé montre la distribution source supposée, conforme à la distribution des SNRs, piquée sur l'anneau moléculaire à 4 kpc. À droite : évolution de l'anisotropie du rayonnement cosmique prédite pour un coefficient de diffusion en $E^{0.6}$ (hypothèse SNR) ou en $E^{1/3}$ (comme attendu théoriquement et suggéré par les rapports d'abondance du rayonnement cosmique), comparée aux contraintes observationnelles. La seconde solution est seule en accord avec les données.

→ Source distribution is more uniforme...

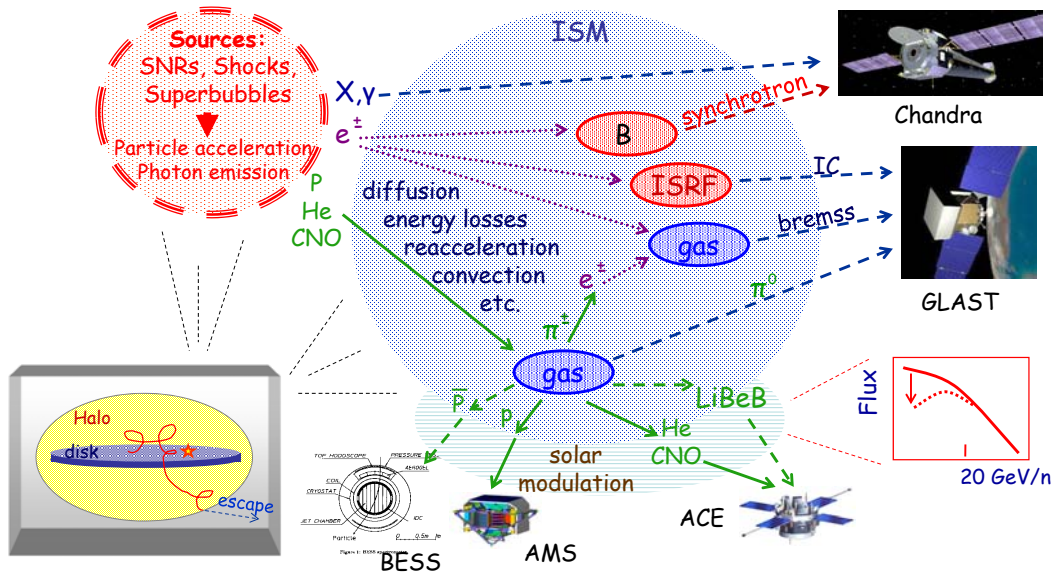

Full transport equation

$$\frac{\partial \psi(\vec{r}, p, t)}{\partial t} = q(\vec{r}, p) \text{ sources (SNR, nuclear reactions...)}$$

$$\begin{aligned} & \text{diffusion} + \vec{\nabla} \cdot (D_{\chi\chi} \vec{\nabla} \psi - \vec{V} \psi) \text{ convection} \\ & \text{diffusive reacceleration} + \frac{\partial}{\partial p} \left[p^2 D_{pp} \frac{\partial}{\partial p} \left(\frac{\psi}{p^2} \right) \right] \\ & \text{E-loss} - \frac{\partial}{\partial p} \left(\frac{dp}{dt} \psi \right) - \frac{1}{3} p \vec{\nabla} \cdot \vec{V} \psi \text{ convection} \\ & \text{fragmentation} - \left(\frac{\psi}{\tau_f} - \frac{\psi}{\tau_d} \right) \text{ Radioactive decay} \end{aligned}$$

$\psi(\vec{r}, p, t)$ – momentum density

Propagation in the ISM et observational constrains

Summary for galactic CR

Everything works fairly well...

- Propagation in the ISM:
 - Complete theory with energy losses, diffusion, in flight nuclear reactions, CR escape, reacceleration, ... impressive results. (see for example GLAPROP model, A. Strong et I Moskalenko)

- Secondaries / Primaries
- Cosmic clock
- Anisotropies
- Theoretical expectations (\sim Kolmogorov spectrum : $D(E) \propto E^{0.36}$)

...except naive acceleration models!

- Observation + models require source spectra $\propto E^{-2.35}$ (high energy spectral shape and $I_{\text{aires}}/I_{\text{aires}}$ ratio "best fit")
- "Softer" (steeper) than standard spectra for strong shocks $f(E^{-2})$

It is possible to find an agreement between diffusive propagation models and standard SNR models,

- Cut off energy, knee, non-linearities, γ -ray emission by SNR, source distribution...

Many parameters \Rightarrow need many observational constrains.

A conciliation exemple CR SM & diffusion

M.Hillas J. Phys., Conf. Ser. 47 (2006) 168 (<http://iopscience.iop.org/1742-6596/47/1/021>)

source ?, composition ?

UHECR, terra incognita

AUGER

UHECR propagation

3 essential effects :

- Energy losses: modify the spectral shape
- Particle confinement (escape depending on energy)
- Spatial and angular diffusion due to magnetic fields. (regular or fluctuating, inhomogeneities, waves)

An extrem case of relativistic kinematics !!!

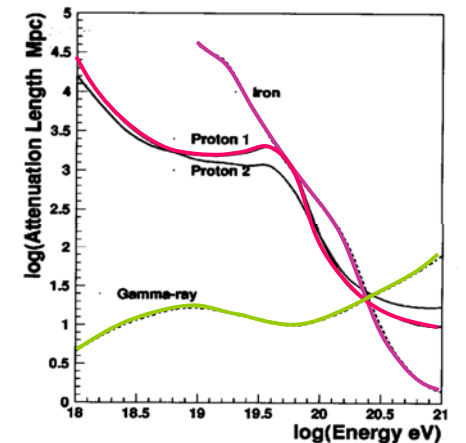

GZK
"cutoff"

Greisen '66, Zatsepin & Kuzmin '66

Energy losses

- $p + \gamma_{2.7K} \rightarrow n + \pi^+; p + \pi^0; p + e^+ + e^-$
- $A + \gamma_{2.7K} \rightarrow (A - 1) + N; (A - 2) + 2N; A + e^+ + e^-$
- $\gamma + \gamma_{2.7K} \rightarrow e^+ + e^-$

Consequences on spectral shape

Protons:
 Photo Pion production
 CMB photons
 $p + \gamma_{\text{cmb}} \rightarrow \Delta \rightarrow p/n + \pi$

Fe:
 photo-dissociation
 on IR bg and CMB

Photons: paires e^+e^-
 on radio bg

Protons energy vs. distance (J. Cronin)
 Energy loss on CMB

UHE Extragalactic Particles

Fluctuation dues to multiple scattering

Protons energy vs. distance (J. Cronin)

UHE Extragalactic Particles

Figure 6: Probability that an observed event at a given energy has its source at a distance greater than the indicated distance. A source spectrum proportional to $E^{-2.5}$ is assumed. Figure provided Paul Sommers, University of Utah.

GZK suppression

• Greisen-Zatsepin-Kuz'min

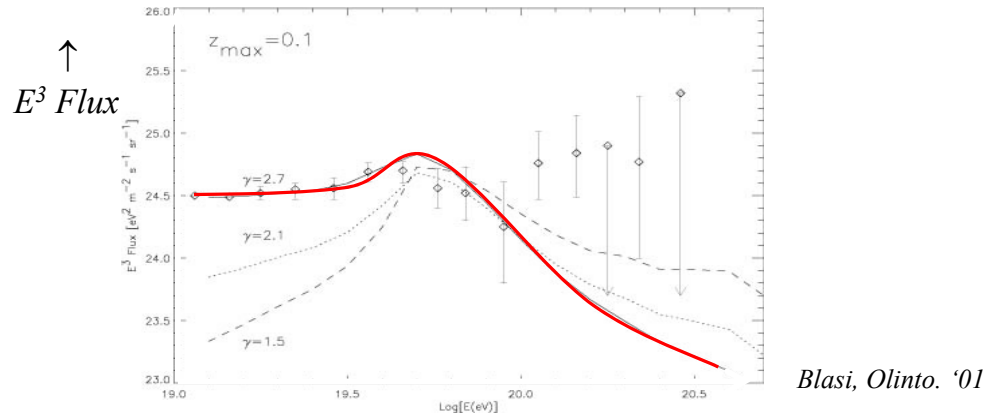

- Distance to the source limited to 100 Mpc for 10^{20} eV protons, and 15 Mpc for 3×10^{20} !
- Actually even worse if particles are deflected ($D_{\text{effectif}} > D_{\text{linear}}$)

Spectrum above GZK cutoff

Depends among other things:

- ☞ From the injection spectrum
- ☞ From the sources cosmological distribution (evolution)
- ☞ From IG magnetic fields

GZK like suppression (Auger)

GZK like suppression (Auger)

MAGNETIC DEFLECTIONS

Galactic magnetic deflection

- 10^{18} eV proton in a $B = 3 \mu\text{G}$ field $\Rightarrow r_g \sim 370$ pc

- 2×10^{19} eV proton in $B = 3 \mu\text{G}$ $\Rightarrow r_g \sim 7$ kpc
- 5×10^{20} eV Fe in $B = 3 \mu\text{G}$ $\Rightarrow r_g \sim 7$ kpc

Propagation the Galaxy

- Galactic magnetic field model

$$\left(\frac{R_{Larmor}}{kpc} \right) = \left(\frac{1}{Z} \right) \cdot \left(\frac{E}{1EeV} \right) \cdot \left(\frac{ZB}{\mu G} \right)$$

- Possible galactic confinement of 10^{20} eV nuclei
- 10^{18} eV neutrons decay length $\beta\gamma c\tau \approx 10\text{kpc} \Rightarrow$ galactic distances

Tracking back direction of proton events $>4 \cdot 10^{19}$ out of the Galaxy, two different field hypothesis [Stanev97]

Pointing at UHECR sources?

Extra-galactic UHECR propagation

2016 F. Montanet - Astroparticle physics ESPAP

From diffusive regime to rectilinear propagation [Sigl]

Time-Energy correlation

Average spectrum
Depends on the strength and coherence length of EG magnetic fields

$$\theta(E) \approx 0.025^\circ \sqrt{\frac{d}{\lambda}} \left(\frac{\lambda}{10 \text{ Mpc}} \right) \left(\frac{B}{10^{-11} \text{ G}} \right) \left(\frac{E}{10^{20} \text{ eV}} \right)^{-1}$$

$$\tau(E) \approx 200 \text{ yr} \left(\frac{d}{100 \text{ Mpc}} \right)^2 \left(\frac{\lambda}{10 \text{ Mpc}} \right) \left(\frac{B}{10^{-11} \text{ G}} \right)^2 \left(\frac{E}{10^{20} \text{ eV}} \right)^{-2}$$

Mapping IG fields with UHECR?

2016 F. Montanet - Astroparticle physics ESPAP

FIG. 1. Full sky map (area preserving projection) of deflection angles for UHECRs with energy 4×10^{19} eV using a linear color scale. All structure within a radius of 107 Mpc around the position of the Galaxy was used. The coordinate system is galactic, with the galactic anti-center in the middle of the map. Positions of identified clusters are marked using the locations of the corresponding halos in the simulation. Note that deflections internal to the Milky Way have not been included.

Diffusion in the Universe

2016 F. Montanet - Astroparticle physics ESPAP

- If they are protons, arrival direction \approx source direction
 $r_L \approx 100 \text{ kpc} \times Z \times (E/10^{20} \text{ eV}) \times (B/10^{-6} \text{ G})^{-1}$
 $\delta\theta \sim \lambda_B/r_L$ deviation per field correlation length $\Rightarrow \Delta\theta \sim \sqrt{D\lambda_B}/r_L$
 \rightarrow Proton astronomy!
- Correlations between arrival directions and sources:
UHECR distribution is NOT ISOTROPIC!!! (AUGER 2007)
 - Confirmation of a GZK limited horizon
 - Few sources in the GZK sphere \rightarrow anisotropic
 - Astrophysical origine is confirmed!
- Arrival time delay
 - $\Delta t \sim \Delta\theta^2 d/c \sim D^2 \lambda_B / r_L^2 c$
 - If eruptive or transient sources (GRBs, TDs), they must overlap in time (otherwise E(t)!)
 - Multiplets of events from same direction observed but no significant ordering in E or deviation.

\rightarrow Correlation must be confirmed! (statistics...)

Matter distribution in the GZK sphere

F.Montanet - Astroparticle physics ESIPAP

PRIMARY RC DETECTION (ON TOP OF ATMOSPHERE)

246

How to characterize the primary particle?

- Mass m
- Electric charge Ze
- Velocity $v = \beta c$
- Lorentz Facteur $\gamma = E/mc^2$
- Momentum $p = mc\beta\gamma$
- Kinetic energy $T = mc^2(\gamma - 1)$

2016

F.Montanet - Astroparticle physics ESIPAP

247

How to characterize the primary particle?

Detector	Observable	Link with the particule
Magnetic spectrometer	Rigidity & Sign of Z	pc/Ze
Time of flight	Velocity/c	β
Proportionnal counters Scintillators Ionisation chamber	Ionisation	$dE/dx = Z^2 f(\beta)$
Čerenkov effect	Č photons density	$dN/dx = Z^2 g(\beta)$
Transition radiation	Number of photons X	$N = Z^2 h(\gamma)$
Calorimeter	Deposited energie	$mc^2(\gamma - 1)$

2016

F.Montanet - Astroparticle physics ESIPAP

248

Transition radiation (cont)

- Angular distribution peaked at small angles around particle direction:
 $\theta \approx 1/\gamma$
- Small yield of X-photons per interface : $N \approx \alpha Z^2 \approx 10^{-2} Z^2$
→ multiply the number of interfaces
→ stack plastic sheets or fibers
- X-ray detection by photo-electric effect: proportional tubes
- Discriminates between particles with same energy and \neq masses at high energies (100 GeV to 1 TeV) (instrumental detection threshold for X-rays).
- Can measure the Lorentz factor γ up to 10^5 . In this case, choose material adequately to have a progressive threshold.

253

Charge particles and cosmic antimatter

Satellite born experiment : AMS-1, PAMELA, AMS-2

- **First satellite based experiments** on cosmic rays : **HEAO-C, Ariel-VI (1979)** → relatively low energy (up to a few 10 GeV/nucleon)
- **First satellite based magnetic spectrometer** en satellite : **AMS-1** on the space shuttle « Discovery » (1998)
- **New generation of experiments:**
PAMELA (since Juin 2006)
AMS-2 (since May 2011)
on the International Space Station → **data up to ~TeV**
and precise measurements of flux of cosmic antiparticles

A nearby Pulsar ?

Mature pulsars: (0.01 < T < 1 Myr)

e^\pm are confined to the pulsar wind nebula until it merges with the ISM. Merger process is fast so that pulsars can be treated as burst-like sources of e^\pm

Contribution could be from a few local pulsars

- Geminga: d = 160 pc, T = 0.37 Myr

- Monogem: d = 290 pc, T = 0.11 Myr

but pair conversion efficiency needs to be high (30 - 40%)

Contribution could be from a large number of pulsars, distant and local, with an assumed continuum distribution and injection spectrum

$$\frac{dN_{e^\pm}}{dE} \propto E^{-1.5} e^{-E/E_p}$$

Charged particles (1 TeV → few 100 TeV)

Covering period from: 2008-12-16 21:08:56 to 2009-01-07 11:29:46

Current Speed: 0.01 knots
Current Course: 0°
Current Lat: -69°48'13.2"
Current Lon: 155°51'54.1"
Current MET: 19 days 13 hrs 35 mins 0.65 sec since launch
Current Altitude: 4720.1444 feet
Current Time: 2009-01-07 11:29:46 UTC

CREAM 2009

1 décembre 2009
au 8 janvier 2010

GM 2010 Jan 08 17:01:00 CREAM_Antarctica_2009-2010

CREAM Cosmic Ray Energetics and Mass

- **Objectives :**
CR composition and spectrum of the different elements (from TeV to ~500 TeV)
- **Acceptance :** 2,2 m² sr
- **Energy measurement:**
 - Calorimeter 20 X₀ (W + scint. fibres)
 - Transition Radiation Detector
- **Identification :**
 - TRD
 - Cherenkov detector "CHERCAM" similar to AMS-2

CREAM experiment

- At TeV energies, the interaction of CR in the calorimeter induces many backscattered secondary particles that one have to veto.
- The "CHERCAM" cherenkov solves this problem by measuring accurately the time of any through going particle as well as achieving a precise charge measurement ($\pm 0,3 e$)

CREAM experiment

Contexte expérimental

The knee

- Is the knee due to:
 - Acceleration mechanisms
 - or to changes :
 - in propagation?
 - in CR sources?
 - in interaction properties (threshold)?

⇒ A diffuse SNR shock acceleration with E_{max} implies a change in composition around $\sim 10^{14}$ eV.

SNR energy limit: $E_{max} \sim Z \cdot 10^{14}$ eV

CR SM with $E_{max} \propto Z$

293

Galactic CR propagation with CREAM

Secondary/Primary ratio

Compatible with propagation models with escape term in $E^{0.6}$

294

AIR SHOWERS DEVELOPMENT MODELS

A peek above the knee !

To measure the inclusive spectrum at the knee, one needs a 10m^2 exposed during 10 years !

The realistic experimental limits are:

- For satellites $\sim 1\text{m}^2$ (sr) during \sim few years
- For balloons, $\sim 10\text{m}^2$ (sr) during $n \times 30$ jours

$\rightarrow E < 10^{15}$ eV

It's time we face reality my friends, we should keep to ground detectors !

295

296

Extensive Air Showers: the phenomenon and the observables

- **The large shower of secondary particles** induced by the interaction of a primary CR in the upper atmosphere can be detected on an extensive area → large effective surfaces to fight against low flux at $E \geq 1000$ TeV
- **Atmosphere used as an calorimeter** (~ 1000 g cm^{-2} at sea level for a vertical shower)
- From the observables, one aims at measuring:
 - Incident direction;
 - Primary energy E_0 ;
 and if possible, get access to the **nature of the primary particle** :
 - distinction γ -hadron ;
 - distinction light nuclei (p, He) - heavy nuclei(Fe)

297

p or nucleus + N or O nucleus → hadronic cascade

- **Hadronic component:** nuclear fragments, nucleons, mesons π , K, etc.
- **Electromagnetic component:** induced by $\pi^0 \rightarrow \gamma\gamma$ and other radiative decays
- **Muonic component:** induced by decays of π^\pm and K^\pm
- **Atmospheric Neutrinos** issued from s π^\pm K^\pm and μ^\pm decays

Primary electrons and γ induce an **electromagnetic shower** consisting mainly of secondary electrons, positrons and γ (muon poor)

298

Shower development

« des giboulées d'électrons »

Rayon cosmiques
par Pierre Auger
1941 PUF

A 10^{19} eV shower

10^{11} particles
at sea level

Photons + electrons (99%),
muons (1%)

299

Ground observables

- **Secondary particles reaching ground**
As a function of the primary energy and of the altitude:
 - Residual Hadrons (nuclear fragments): not numerous ($> 11 \lambda_{int}$).
 - e^\pm : the more numerous at shower development maximum.
 - μ^\pm : most reach ground and may penetrate deep underground.
 - γ secondaries: may be detected at ground level via e^+e^- pair conversion (e.g. Cherenkov effect in water).
- **Photons (visible, UV) emitted along the trajectories of charged particles (Cherenkov effect, N_2 fluorescence) during the shower development**
→ Calorimetric 3D information !
- **Radio emission by the shower particles in the geomagnetic field or by the induced plasma.**

300

Temporal aspects

- A light speed moving "pancake" of charged particles.
- This front is more or less curved depending on the shower development stage.
- The front thickness (~ 10 m) induce as signal time spread in each detector.
- The arrival time differences at ground on the sampling detectors \rightarrow arrival direction ($\Delta\theta \approx 1^\circ$).
- The Cherenkov light front (forward emission) is thinner (\sim m) than the charged particle front \rightarrow well defined timing.

301

Time structure

Fine galette (quelques dizaines de ns) de particules traversant le ciel avec une vitesse $v \sim c$.

302

EM shower Longitudinal development

- Mean number of particles (e^+, e^- or γ) crossing a plan \perp to the shower axis after a slant depth t (in units of X_0).
- As long as the ionization losses are small wrt radiation losses (bremsstrahlung and pair prod) the number of particle increase exponentially.
- When the mean energy per particle decreases below the critical energy ($E_c \approx 84,2$ MeV in air), the number of particle decreases (shower extinction phase).
- At the transition between the two phases, (maximal development), the mean energy is equal to the critical energy.

303

Radiative processes ($E > E_c$)

Bremsstrahlung :

Pairs production :

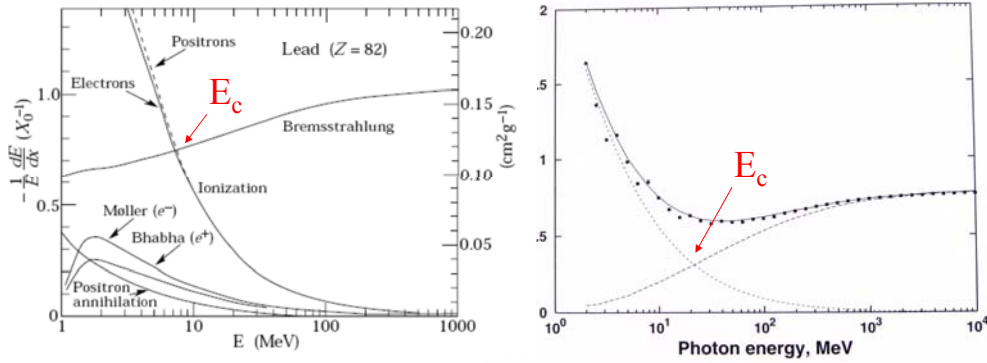

Radiation length X_0 :

- energy loss = $1/e$ due to bremsstrahlung
- $7/9$ of the range of a γ due to pair production.

In air : $X_0 = 36.7\text{g/cm}^2$

304

EM cascades (Rossi & Greisen)

Critical energy: below this energy, ionization losses dominate.

Simplified development model (Heitler)

- Cascade consisting of only one type of particles having an interaction length λ .
- At each interaction, 2 particles of same type are emitted sharing the energy exactly in 2.

λ								
X =	1	2	3	4	5			
N =	2	4	8	16	32			
E =	1/2	1/4	1/8	1/16	1/32			$E_c = E_0/32$

Longitudinal development

- After t radiation length, there are 2^t particles with energy

$$E = E_0/2^t$$

soit : $t \ln 2 = \ln(E_0/E)$

- The particles of energy E are produced at thickness:

$$t(E) \approx \ln(E_0/E)$$

- The maximal development of the shower is reach for a thickness:

$$t_{max}(E_0) \approx \ln(E_0/E_c)$$

- More realistic models agree with this rough estimate.

Simplified development model (Heitler)

$$X = n\lambda$$

$$N(X) = 2^n$$

$$E(X) = E_0/2^n$$

$$E(X_{max}) = E_c \Rightarrow \begin{cases} X_{max} = \lambda \log_2(E_0/E_c) \\ N_{max} = E_0/E_c \end{cases}$$

X =	1	2	3	4	5			
N =	2	4	8	16	32			
E =	1/2	1/4	1/8	1/16	1/32			$E_c = E_0/32$

Longitudinal development: Approximation "A" (B. Rossi, K. Greisen)

- Approximation "A" describes the shower development phase where only bremsstrahlung and pair creation are in action.
- From Bethe-Heitler theory, one obtains des integro-differential linear and coupled equations leading to:
 - $\Pi(E, t)dE$ = average number of e^\pm with energy $\in [E, E + dE]$, at tX_0 depth
 - $\Gamma(W, t)dW$ = average number of γ with energy $\in [W, W + dW]$, at tX_0 depth
- The simplifying factor is the absence of any energy scale.

309

Approximation A (cont)

- $\Pi(E, t)dE$ = average number of e^\pm with energy $\in [E, E + dE]$, at tX_0 depth
- $\Gamma(W, t)dW$ = average number of γ with energy $\in [W, W + dW]$, at tX_0 depth
- Initial condition :
 - If the primary particle is a γ : $\Gamma(W, 0) = \delta(E - E_0)$
 - If the primary particle is an e^\pm : $\Pi(E, 0) = \delta(E - E_0)$
- Obvious special solutions:
 $\Gamma(W, t) = f(t)/W^{s+1}$ et $\Pi(E, t) = g(t)/E^{s+1}$
 (absence of energy scale)

... but they dont satisfy the initial conditions!

310

Approximation A (suite)

- The obvious solutions (power-law spectra, therefore scale invariant) correspond to an initial condition interesting in itself: an incident beam with a power law spectrum with an integral spectral index s .
- These special solutions form a base and a solution that fulfills the initial condition (photon or electron with an energy E_0) is obtained from a superposition of $1/E^{s+1}$ spectra (Mellin transformation, analogue to Fourier or Laplace transforms).
- Result : for a given value of t , the particle spectrum is very close to a power law $1/E^{s+1}$ with a value of s that varies with t and $y = \ln(E_0/E)$ following:

$$s = \frac{3t - 1}{t + 2y}$$

- The number of particle with energy E is maximal for $s = 1$

311

Taking into account ionization energy losses: the "age" parameter

- Approximation A is not valid anymore when the electron mean energy E_c is close to the critical energy E_c .

- One can modify the above results:

$$y = \ln\left(\frac{E_0}{E_c}\right) \quad \text{et} \quad s = \frac{3t}{t + 2y}$$

- Semi empirical formula given by Greisen for an incident γ , for the mean number of electrons after traversing t radiation length:

$$\bar{N}_t = \frac{0.31}{\sqrt{y}} \exp\left[t\left(1 - \frac{3}{2} \ln s\right)\right]$$

- The parameter s increase with t . It is < 1 during the development phase, reaches 1 at the maximal development stage for $t_{max} = y = \ln(E_0/E_c)$ and is > 1 during the extinction phase.
- s is called the "age".

312

EM showers : some orders of magnitude

Primary γ energy E_0	Thickness traverse $t_{\max} X_0$ ($g\ cm^{-2}$)	Altitude (m)	$N_e(t_{\max})$
30 GeV	216	12000	50
1 TeV	345	8000	1200
1000 TeV	600	4400	$0,9 \times 10^6$
10^{19} eV	936	1200	$7,4 \times 10^9$
10^{20} eV	1021	0	$7,0 \times 10^{10}$

313

EM shower average profiles

314

EM cascades (Rossi & Greisen)

Parametrisation (Greisen) and Monte Carlo (EGS4)
photons 1TeV, $E_c=10$ MeV

315

Shower size i.e. number of electrons at ground level as an energy estimator

- At maximal development level, the mean number of electrons quasi proportional to the primary energy ($y = \ln(E_0/E_c)$).
- Fluctuations on N_e :
 - Fluctuations on the depth of first interaction (exponential law)
 - Fluctuations in the shower development (approximately log-normal because of the multiplicative behaviour)
 - Sampling fluctuations (depends on the type of detectors, their arrangement on the ground etc.)
- If the altitude of the maximal development is known (direct optical measurement), or if one can estimate the age independently (from lateral distribution of the electrons) one can avoid the first kind of fluctuations.
- Fluctuations are minimal at the maximum of development.

316

Cascades EM (Rossi & Greisen)

Shower to shower fluctuations
 10 showers at 10^{14} eV compared to the average of 100 showers.

GAMMA-RAY (EM) INDUCED SHOWERS

10 γ
 300 GeV

10 protons
 300 GeV

*Simulations de
 M. de Naurois*

Electromagnetic showers (e^\pm or γ primary)

Dominating phenomena

- Radiation processes:
 - Bremsstrahlung of e^\pm
 - Pair production ($>MeV$) e^+e^- pairs
- Multiple scattering
 (small angular deflections) of e^\pm
- Energy losses by e^\pm
 - par ionization
 - atomic excitation

In the Coulomb field of nuclei

γ induced shower 300 GeV

Roughly symmetric around the axis

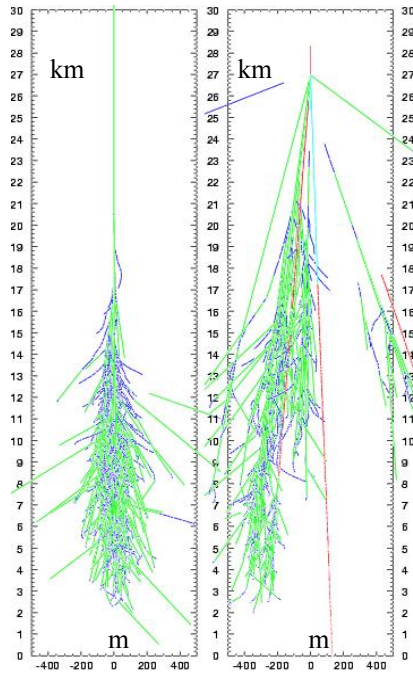

Small transverse dispersion (multiple scattering)

(almost) no muons

...

(unless $E_0 > 1$ PeV)

Essentially $e^+ e^-$ and γ secondaries

proton induced shower 300 GeV

Large transverse momentum

Muon component (from mesons decays)

A hadronic shower does contain EM sub-showers

Optical photon emission by showers

- Showers charged particles emit light:
 - **Cherenkov light** : very collimated along the shower axis (Cherenkov angle at 1 Atm. $\approx 1^\circ$) threshold depending on the altitude : at ground 22 MeV for e^\pm et 4.5 GeV for μ^\pm (20 photons per m per $\beta \approx 1$ charged particle at 1 atm) Essentially used for gamma-ray astronomy
 - **Nitrogen fluorescence**: isotropic emission (≈ 4 photons per electron per m) Essentially used at UHE $\geq 10^{18} eV$.
- This light detected by ground telescopes gives us very rich information on the 3D development of the showers. It give a quasi calorimetric reliable measurement of the energy.
- ... but optical detectors can only work during moonless clear sky nights ($\approx 10\%$ duty cycle).

Lecture on Imaging & Cherenkov Detectors

HADRONIC SHOWERS MODELS AND DETECTION

"Hadronic" showers (proton ou noyau primaire)

- Great complexity implying the use of numerical simulations:
 - Many length scales : nucleon interaction length, pion interaction length, EM radiation length, atmosphere density height scale...
 - Superposition of a nuclear cascade, a pionic cascade and an electromagnetic cascade (the later from π^0 decay γ).
 - Large fluctuations in the multiplicity of secondaries.
- But simulations are subject to many uncertainties:
 - p+N or N+N interactions: sensitivity to nuclear models.
 - Energy range unexplored by accelerators and colliders : sensitivity to nucleon structure functions (parton distributions) and fragmentation functions extrapolated far from the measured regions.
 - The inelasticity and in general the very forward diffractive physics is not well measured in fixe target experiment (even worse at colliders). Still, the main behavior observed on EM showers remains valid.

325

From EM to Hadronic showers

- The main observables are the same:
 - Number of electrons, gamma but also muons at ground and their lateral distributions.
 - Longitudinal profile and maximal dev. altitude (optical detectors).
 - Number of muons at ground level and lateral distribution of muons.
- Feynman scaling is rather well verified in the fragmentation: it plays an role analogue to that of Bethe-Bloch formulae for EM showers (absence of mass/energy scale).
- Simulations have allowed to establish empirical formulae inspired by EM showers useful for quick estimates (T.K. Gaisser, A.M. Hillas)

326

327

Interaction and radiation lengths in atmosphere

328

Development of Hadronic vs EM showers

329

2016

F.Montanet - Astroparticule physics ESPAP

Gaisser longitudinal Parametrization

Gaisser Hillas formulae :

$$N_e(X - X_1) = N_e^{max} e^p \left(\frac{X - X_1}{X_{max} - \lambda} \right)^p \exp - \left(\frac{X - X_1}{\lambda} \right)$$

$$\text{avec } p = \frac{X_{max} - \lambda}{\lambda}$$

Averaging on X_1 depth of 1st interaction :

$$\bar{N}_e(X) = N_e^{max} \frac{p}{p+1} e^p \left(\frac{X}{X_{max} - \lambda} \right)^{p+1} \exp - \left(\frac{X}{\lambda} \right)$$

$$X_{max} = X_0 \log \left(\frac{E_0}{\epsilon_0} \right)$$

$$N_e^{max} = \frac{E_0}{\omega}$$

Radiation length : $\approx 36.7 \text{g/cm}^2$

Critical energy : $\epsilon_0 \approx 74 \text{eV}$

Empirical relation between size and energy: $\omega \approx 1.7 \text{GeV}$

Incident nucleus interaction length (of energy E_0) $\lambda_N \approx 70 \text{g/cm}^2$

330

Longitudinal developpment

Xmax and energy :

$$X_{max} \approx X_0 \log \left(\frac{E_0}{\epsilon_0} \right)$$

$$\Rightarrow 80 \text{g/cm}^2 \text{ per energie decade}$$

Nuclei :

Superposition principle : a nucleus $^A N$ is equivalent to A protons.

Thus :

$$X_A^{max} = X_0 \log \left(\frac{E_0}{A \epsilon_0} \right)$$

$$= X_p^{max} - X_0 \log(A)$$

For example iron/proton $A = 56$:

$$X_0 \log(A) = 36.7 \log(56) = 148 \text{g/cm}^2$$

331

2016

F.Montanet - Astroparticule physics ESPAP

Structure in space

Shower to shower fluctuations largely due to the depth of the first interaction.

2016

F.Montanet - Astroparticule physics ESPAP

332

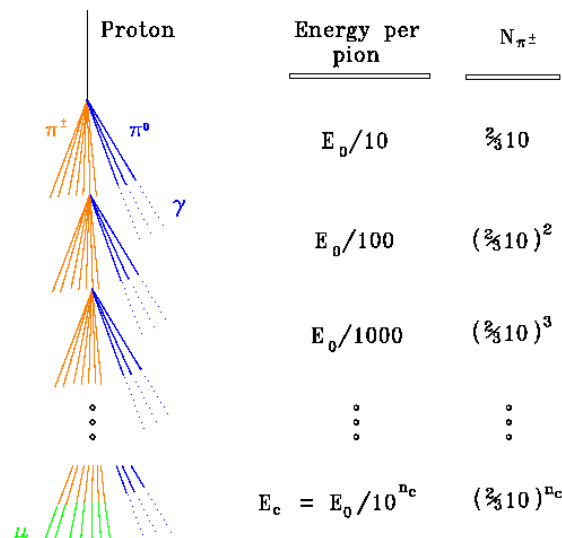

Primary identification

- Requires a good statistics and a good knowledge of the initial energy, the shower angle (+ systematic corrections because of atmospheric attenuation)

333

A simplified development model

334

Radial extension

The radial distribution is determined by **the mean transverse momentum (P_T)** from hadronic interactions and by **multiple scattering**. In air, the Molière radius is ≈ 75 m.

Molière radius ($\sim 1/4$ of the radiation length) :

$$\langle \delta\theta^2 \rangle = \left(\frac{21\text{MeV}}{E} \right) \delta X$$

$$r_1 = \left(\frac{E_s}{E_c} \right) X \approx 9.3 \text{ g/cm}^2$$

Nishimura, Kamata, Greisen :
multiple scattering + transverse momentum

$$xf(x) = C(s)x^{(s-1)}(1+x)^{(s-4.5)}$$

with : $x = \frac{r}{r_1}$

normalization tel que :

$$2\pi \int_0^\infty xf(x)dx = 1$$

339

$e^+ + e^-$ lateral density

F.Montanet - Astroparticule physique ESPAP

340

Lateral evolution

The density as a function of the distance to the center of the shower is characterized by a **lateral density function (LDF)**

$$\rho(r) \propto k \times r^{-[\eta+f(r)]}$$

where f et k depends on the type of detectors used where η depends on the incident angle of the shower and the primary energy.

For $r > 800m$ this (empirical) expression must be modify as $(r/800)^{1.03}$

Shower Density Lateral Distribution (simulation)

Detector Signal Density
(equiv.muons/ m^2)

Particle energy distribution

Rossi Greisen :

$$\frac{dN}{d(\log E)} \approx \frac{1}{E^{s+1}}$$

E.Nerling (thesis) :

$$f_e(E, s) = a_0 \frac{E}{(E + a_1)(E + a_2)^s}$$

$$a_1 = 6.42522 - 1.53183.s$$

$$a_2 = 168.168 - 42.1368.s$$

E en MeV

$$a_0^{-1} = \int_{\log E_{cut}} f(E, s) d(\log E)$$

Excess e^- at low energy (ionization)
