Introduction

- MiniBooNE has collected the largest sample of low energy CCQE events to date. Aguilar-Arevalo et. al., PRL 100 (2008) 032301

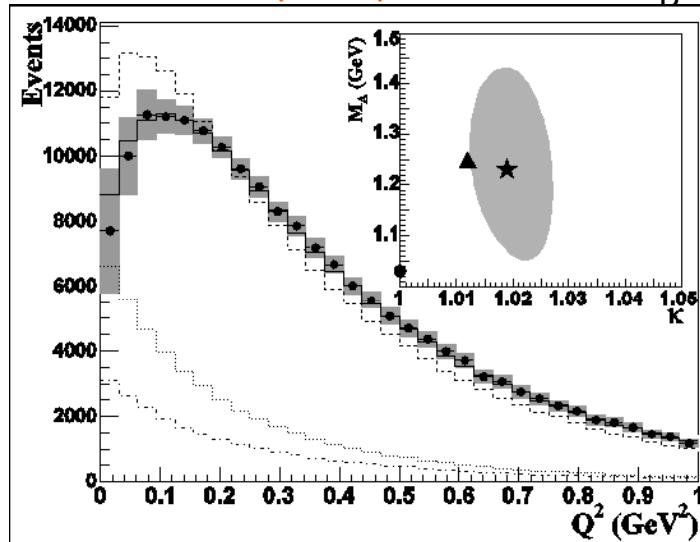

$$\langle E_{\nu} \rangle \sim 750 \text{ MeV}$$

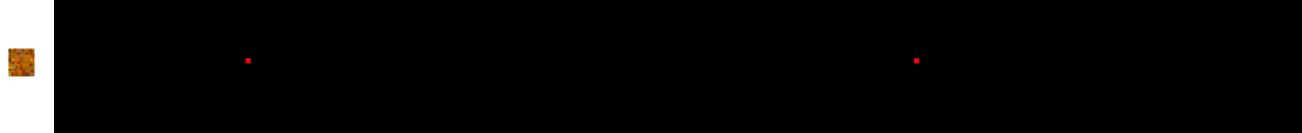

- CCQE is relevant for **oscillation** experiments
- CCQE is interesting by itself:
 - **Axial form factor** of the nucleon (M_A)
 - **Nuclear correlations**

Introduction

- The shape of $k d^2/d\cos\theta dE_\nu$ is accurately described by a Global Fermi Gas Model Smith, Moniz, NPB 43 (1972) 605 with: $E_B = 34$ MeV, $p_F = 220$ MeV

But

- $M_A = 1.23 \ll 0.20$ GeV
consistent with $M_A = 1.2 \ll 0.12$ GeV (K2K)
higher than $M_A = 1.01 \ll 0.01$ GeV (${}^0d; {}^0p; (e; e')$; BBBA07)
 $M_A = 1.05 \ll 0.08$ GeV (mainly ${}^{12}C$, 3-100 GeV, NOMAD)

The model

- Our aim: realistic description of CCQE in nuclei
compare to MiniBooNE data (modified Smith-Moniz ansatz)
- Relevant hadronic degrees of freedom: $\bar{\nu}$, N, f (1232)
- Ingredients:
 - Elementary process $\bar{\nu} + n \rightarrow e + p$
 - Fermi motion
 - Pauli blocking
 - Nuclear binding
 - Nucleon spectral functions
 - Medium polarization (RPA)

and also

- Non CCQE background (cannot be separated from CCQE in a model independent way)

The model

- Elementary amplitude for

$$I^\circledR J_\circledR$$

where I^\circledR and

$$J_\circledR = F_1^V + F_2^V + F_A + F_P$$

$$F_{1;2}^V \leftarrow \text{BBBA07} \quad Q^2 = i (k \cdot k^0)^2$$

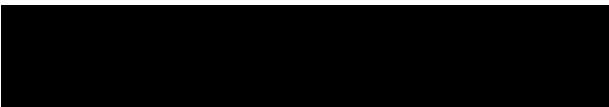

$$F_A \quad F_P \quad F_A \leftarrow \text{PCAC}$$

$$g_A = 1:26 \leftarrow \text{neutron } \tau \text{ decay} \quad M_A = 1 \text{ GeV}$$

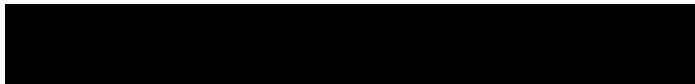

Using PCAC and γ -pole dominance: $\boxed{\dots} \leftarrow \text{Goldberger-Treiman}$

The model

■ Local Fermi Gas

- Fermi Motion of initial nucleons:

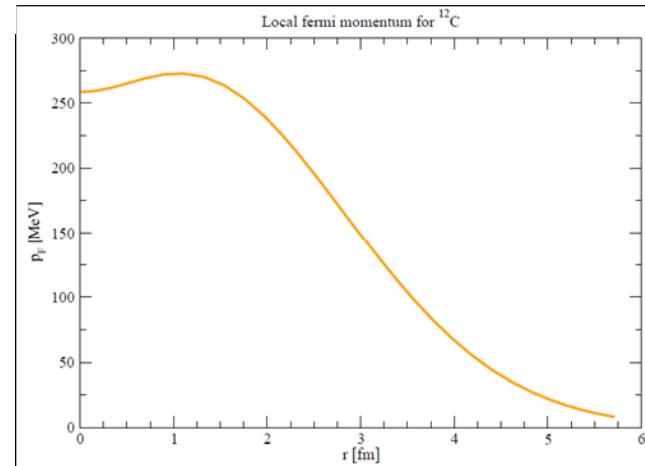

- Pauli blocking of final nucleons:

■ Mean field potential

- Density and momentum dependent
- Parameters fixed in p-Nucleus scattering Teis et. al., Z. Phys. A 346 (1997) 421
- Nucleons acquire effective masses

The model

Spectral functions

- The momentum distribution of a nucleon with 4-momentum p is

$$\frac{1}{\epsilon - \omega + i\Gamma}$$

 \leftarrow nucleon selfenergy

- For final nucleons (above the Fermi sea)

$$\frac{1}{\epsilon - \omega_0 + i\Gamma_0}$$

\leftarrow collisional
broadening
GiBUU

-  is obtained from  with a dispersion relation assuming that at the pole position:

$$\frac{1}{\epsilon - \omega_0 + i\Gamma_0} = \frac{1}{\epsilon - \omega_p + i\Gamma_p}$$

- For initial nucleons (**holes**) we take 

$$\frac{1}{\epsilon - \omega_0 - i\Gamma_0}$$

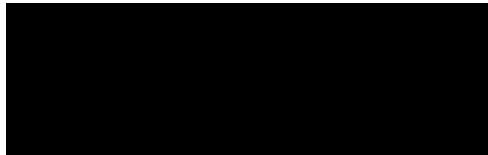

The model

■ RPA nuclear correlations

"In nuclei, the strength of electroweak couplings may change from their free nucleon values due to the presence of strongly interacting nucleons"

Singh, Oset, NPA 542 (1992) 587

■ For the axial coupling g_A :

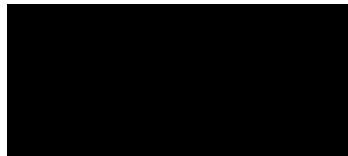

$\cdot \chi_3$ dipole susceptibility

g' Lorentz-Lorenz factor $\sim 1/3$

Ericson, Weise, Pions in Nuclei

■ The quenching of g_A in Gamow-Teller \pm decay is well established

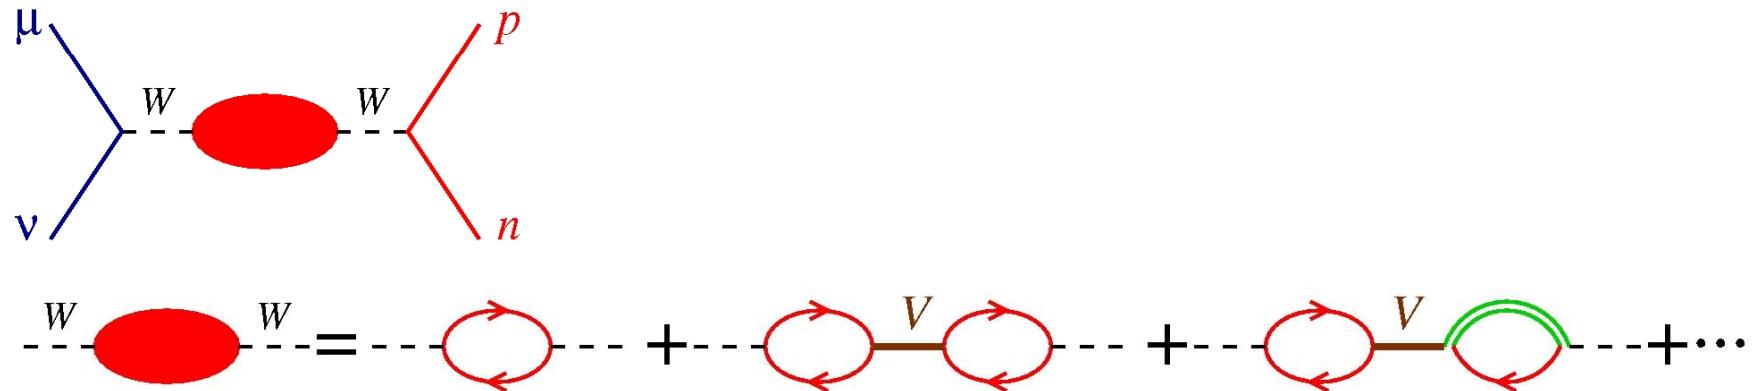

Wilkinson, NPA 209 (1973) 470

The model

■ RPA nuclear correlations

■ Following Nieves et. al. PRC 70 (2004) 055503 :

V_{NN}

■ In particular

■ ↗ spectral function **changes** in the **nuclear medium** → so does J_A^A

The model

■ RPA nuclear correlations

- **RPA approach** built up with single-particle states in a Fermi sea
- Simplified vs. some theoretical models (e.g. continuum RPA)
- Applies to inclusive processes; not suitable for transitions to discrete states

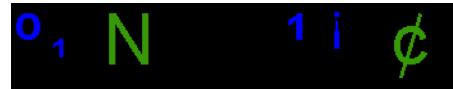

But

- Incorporates explicitly γ and β exchange and f -hole states
- Can be inserted in a unified framework to study QE, 1^\pm , N-knockout, etc
- Has been successfully applied to γ , π and electro-nuclear reactions
- Describes correctly ... capture on ^{12}C and LSND CCQE
Nieves et. al. PRC 70 (2004) 055503
- **Important at low Q^2** at MiniBooNE energies

The model

- Non CCQE background (GiBUU transport model)

- Most relevant processes:

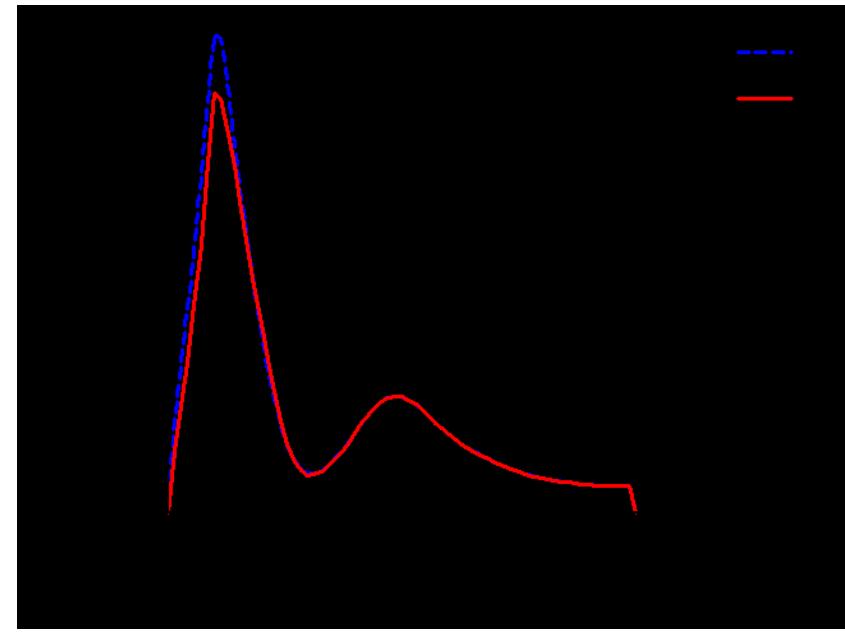

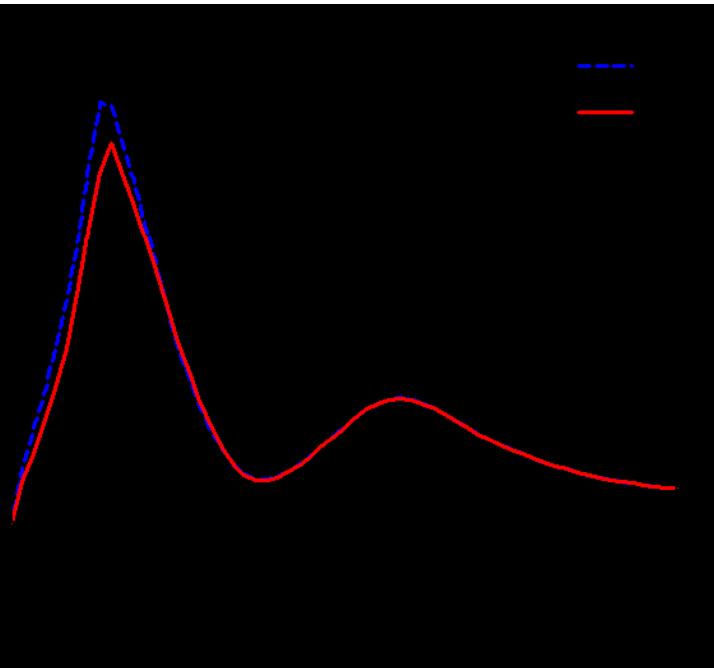

followed by $\text{e}^- \text{ N} \rightarrow \text{N}^+ + \text{N}$ (^ less decay mode)

or by $\text{e}^- \text{ N} \rightarrow \text{N}^+ + \text{N}$ and then $\text{N}^+ + \text{N} \rightarrow \text{N}^+ + \text{N}$ (^ absorption)

- Details in the talk by Tina Leitner

Results

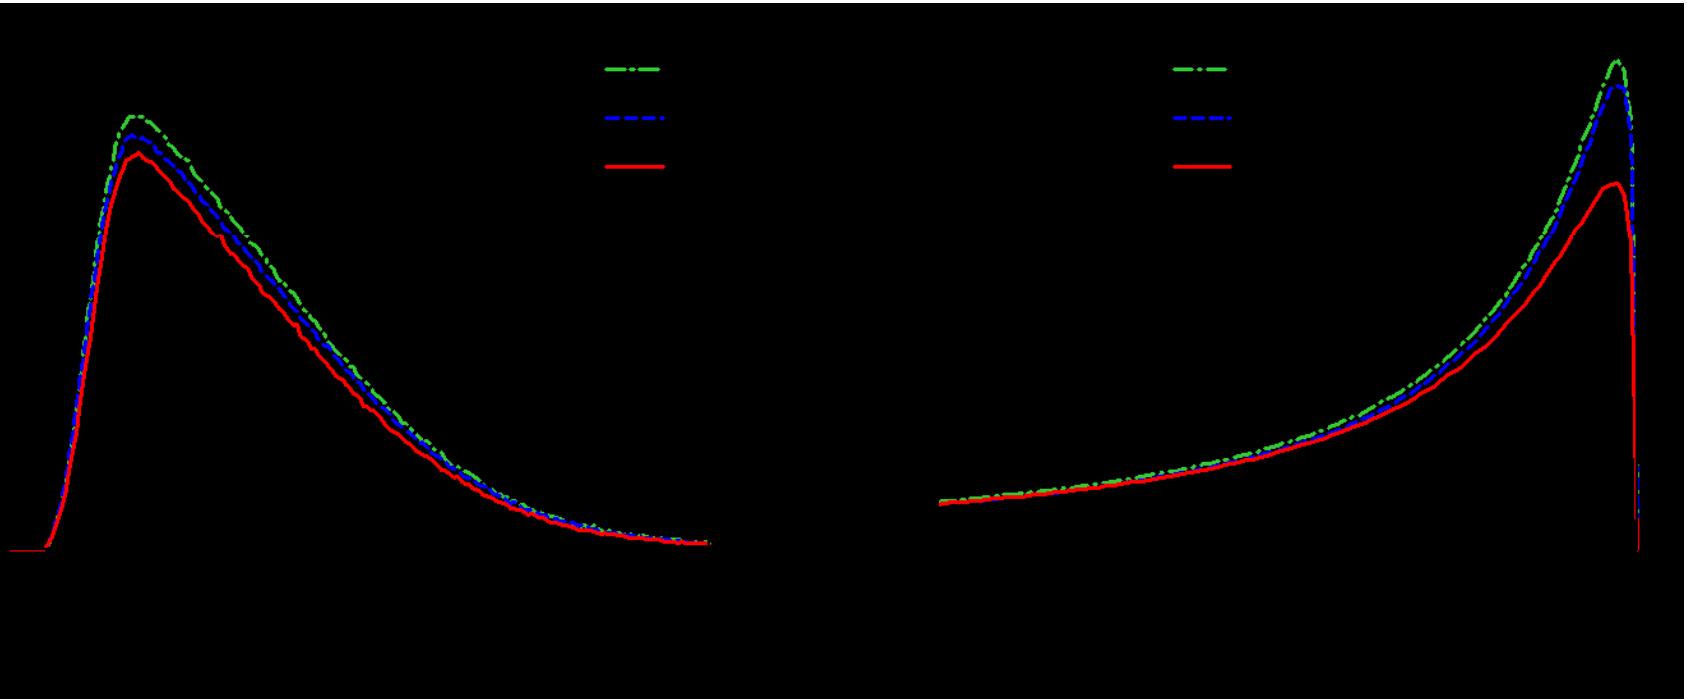

- Comparison to inclusive electron scattering data

- Missing strength in the **deep region**:
more complete many-body dynamics required [Gil et. al., NPA 627 \(1997\) 543](#)
- RPA less relevant than in the weak case

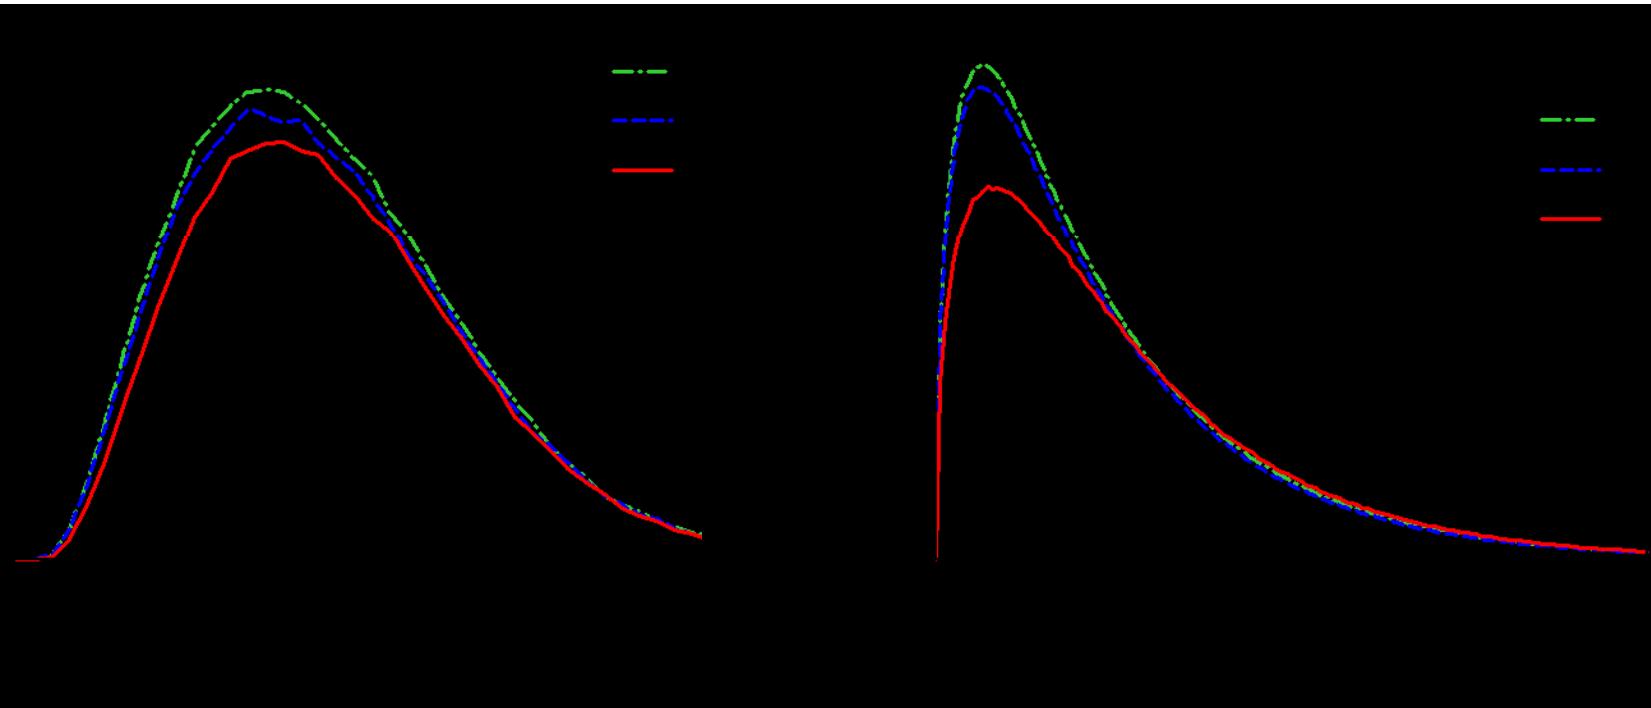

Results

- Differential cross sections averaged over the MiniBooNE flux

Results

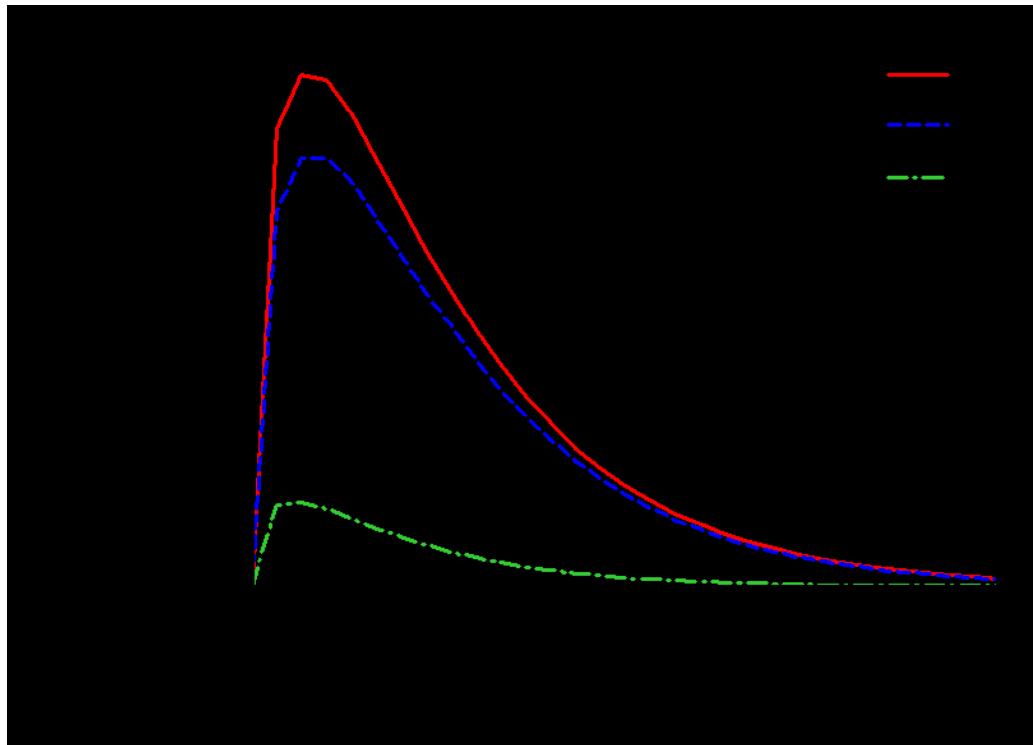

- Differential cross sections averaged over the MiniBooNE flux

- RPA correlations cause a **considerable reduction** of the c.s. at **low Q^2** and **forward angles**

Results

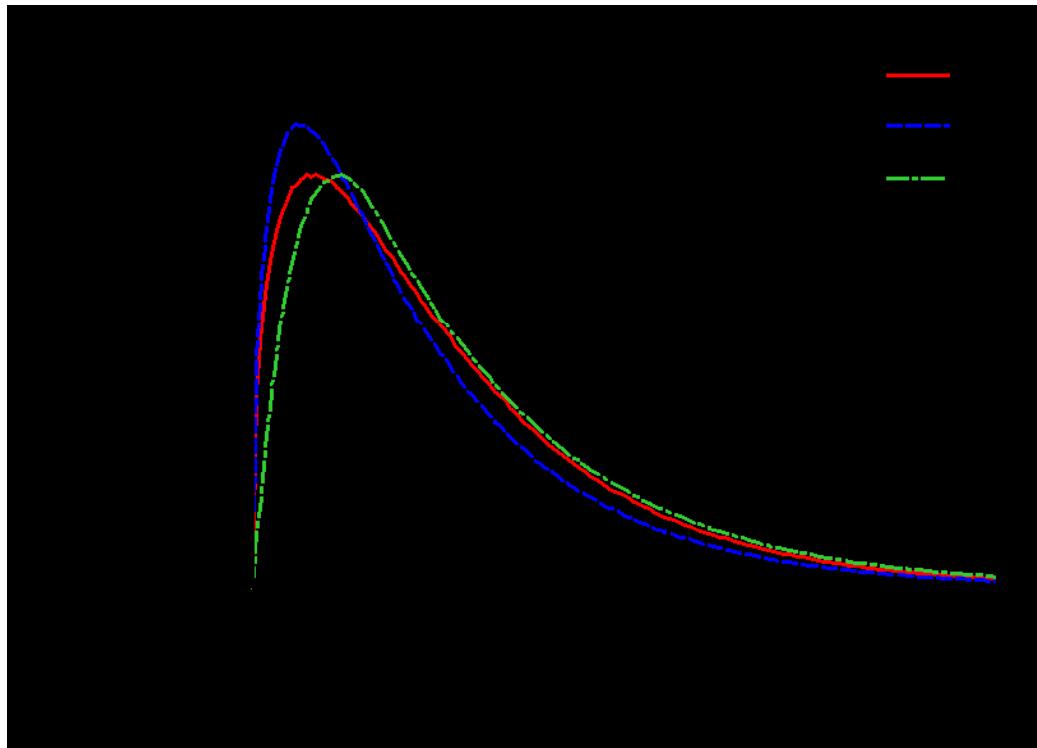

- CCQE + non-CCQE background (measured quantity)

non CCQE
total CCQE + like

Results

- Comparison to the modified Smith-Moniz ansatz (shape)

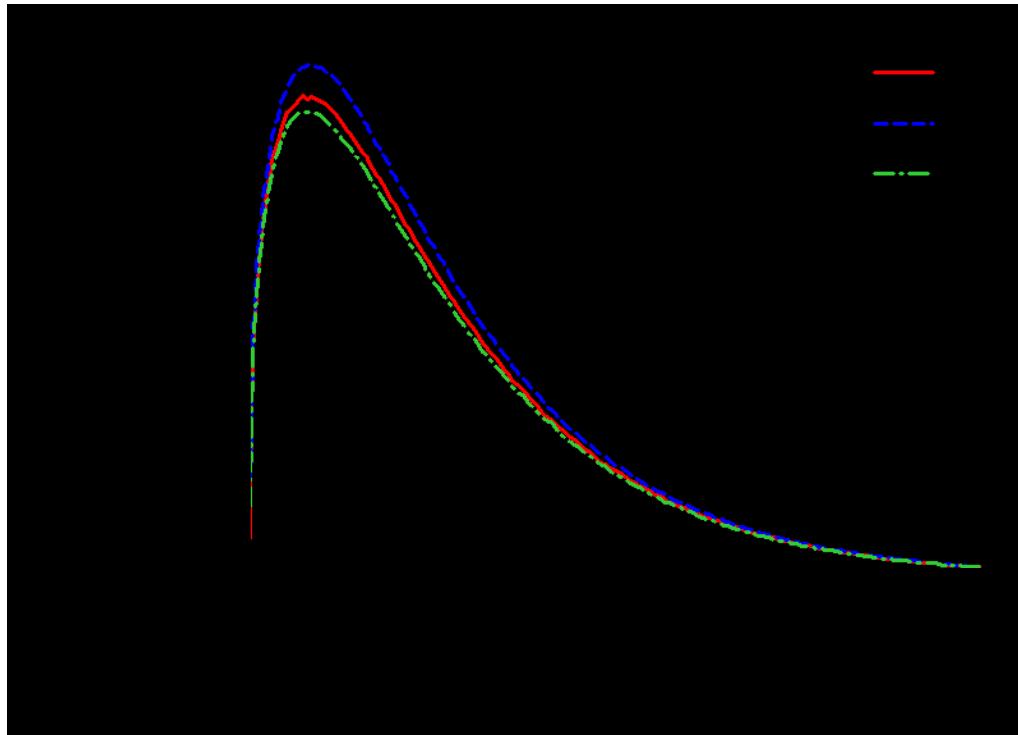

- The effect of RPA brings the shape of the Q^2 distribution closer to experiment keeping $M_A = 1 \text{ GeV}$

Results

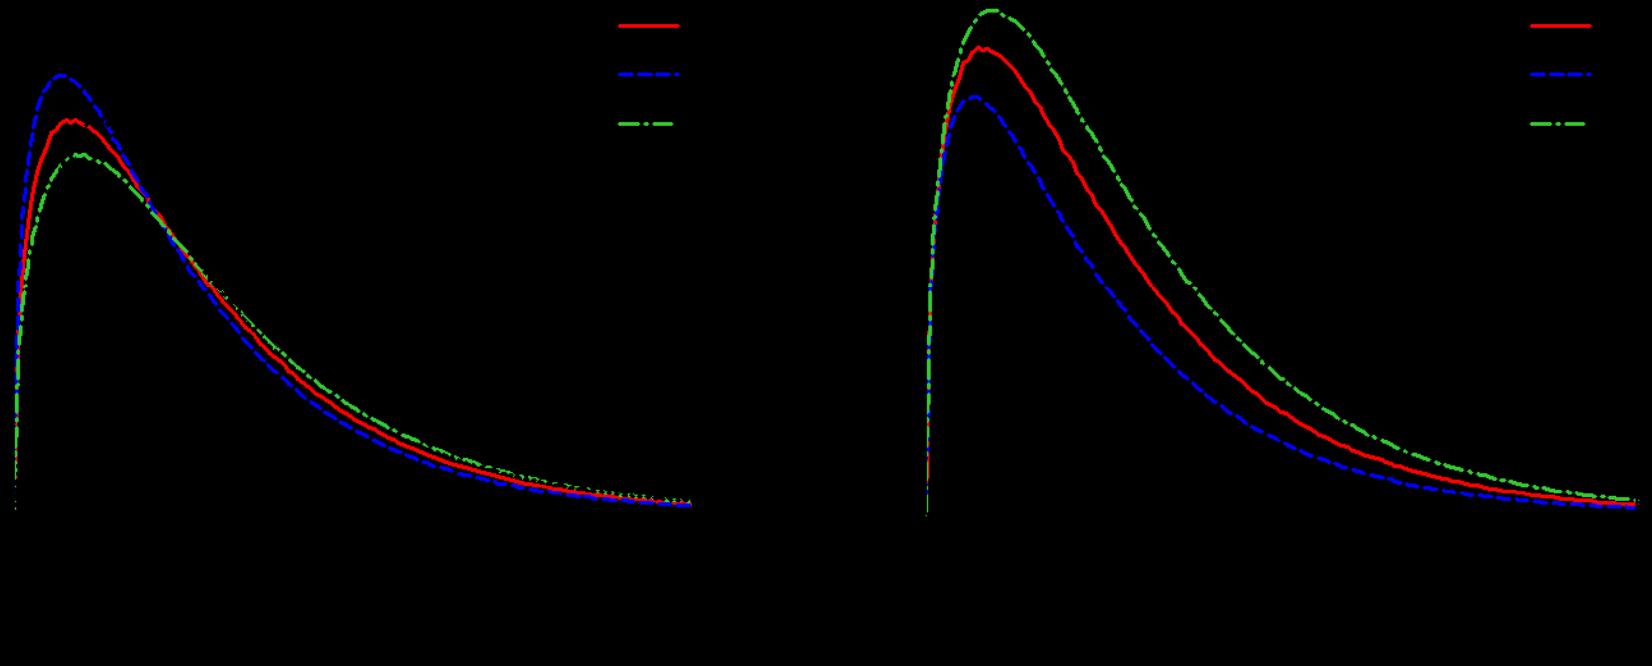

■ Changing $g' = 0.5-0.7$

- Leaves the **shape unaltered**
- Small changes in the integrated cross section $k^1 = 3.1-3.4 \times 10^{-38} \text{ cm}^2$

Results

■ Changing M_A

- The experimental shape is better described with $M_A=1$ GeV
- There are large differences in the integrated cross section

M_A [GeV]	0.8	1.0	1.2
$k^1 [§ 10^{-38}cm^2]$	2.5	3.2	3.7

Conclusions

- We have developed a model for CCQE starting from a Local Fermi Gas but incorporating important many body corrections: nucleon spectral functions, medium polarization (RPA).
- RPA: strong reduction at low q^2 (quenching)
- Good description of the shape of the MiniBooNE q^2 distribution with $M_A=1$ GeV
- A larger integrated CCQE cross section would require $M_A>1$ GeV

Conclusions

- There is (nuclear) physics beyond the naive Fermi Gas Model.

Conclusions

- There is (nuclear) physics beyond the naive Fermi Gas Model.
