

Chamonix 2016 – Session 1  
*Lessons learned*

J. Wenninger & K. Fuchsberger

- ❑ Lessons from LHC operation in 2015 – G. Pappoti
- ❑ LHC Operation and Efficiency in 2015 – M. Solfaroli
- ❑ Machine Protection at 6.5 TeV – J. Uythoven
- ❑ Collimation System Performance – B. Salvachua
- ❑ RF and Transverse Damper Systems – P. Baudrenghien
- ❑ Circuit Performance at 6.5 TeV and beyond – A. Verweij

# 25 ns – yes we can do it !

- Invested a lot of time in scrubbing and special physics.
- Intensity ramp-up lasted until the end – and was not completed.
- Real production started in September only.
- Availability for stable beams during 25ns similar to 2012.

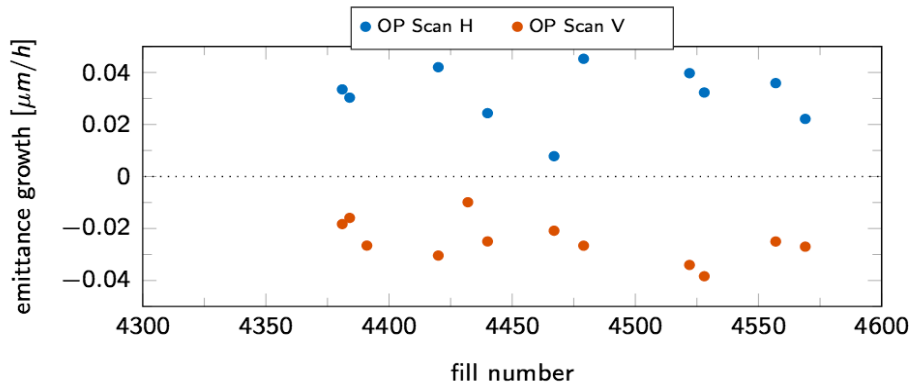

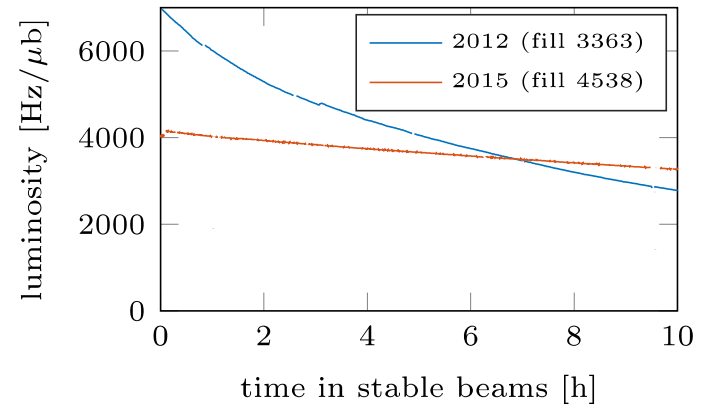

- ❑ The target of 5-10 fb<sup>-1</sup> may have been missed, but we also lost ~4 weeks of running in 2015.
- ❑ In the last week, with 2244 bunches, the performance was similar to 2012 ~ fm<sup>-1</sup> / week. ***We are in the starting blocks for run2!***

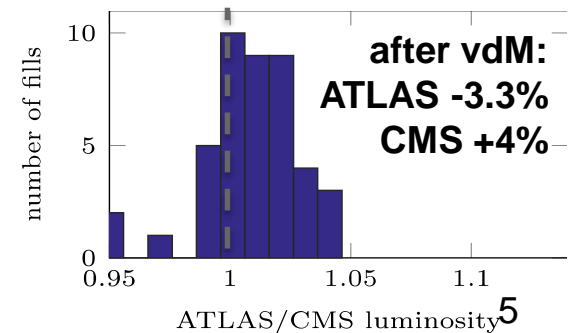

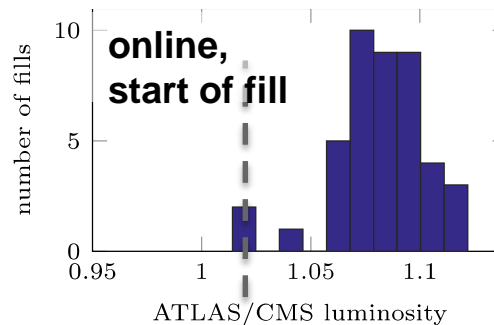

- Healthy luminosity lifetime ~30-40 h favours long fills (> 20 hours).

- Synchrotron radiation damping is clearly observable.
  - *Vertical emittance shrinking during fills  $\rightarrow$  contribution to long L lifetime.*

- (**Fake**) luminosity imbalance triggered machine studies that revealed a waist offset of 20cm at the IPs:

$\beta^* = 84 \text{ cm (not 80 cm)}$

## How long do we stay at injection?

Time at injection for PROTONS PHYSIC stable beam fills

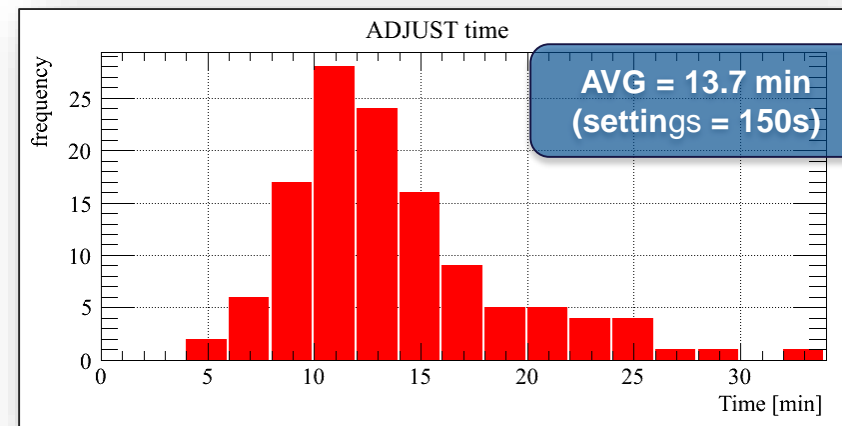

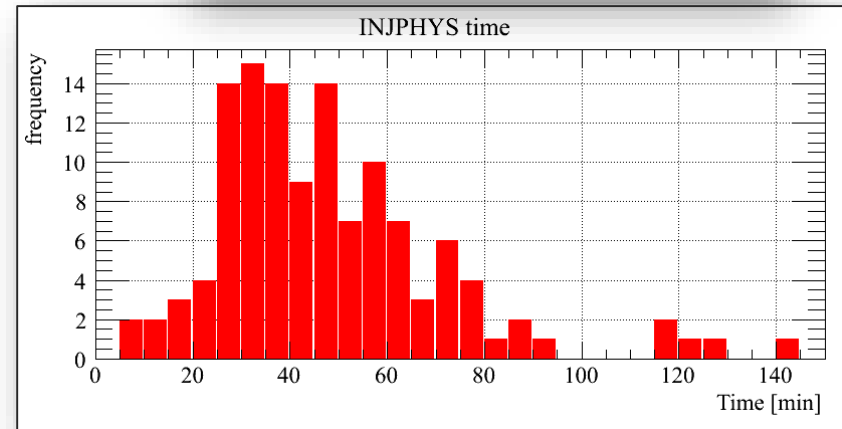

Average nb of inj/fill: 22  
SPS supercycle length: 59s  
Time at injection in a perfect world: 22 + 15 = 37mins

Average time really spent at injection  
~1h30

D.Jacquet @Evian

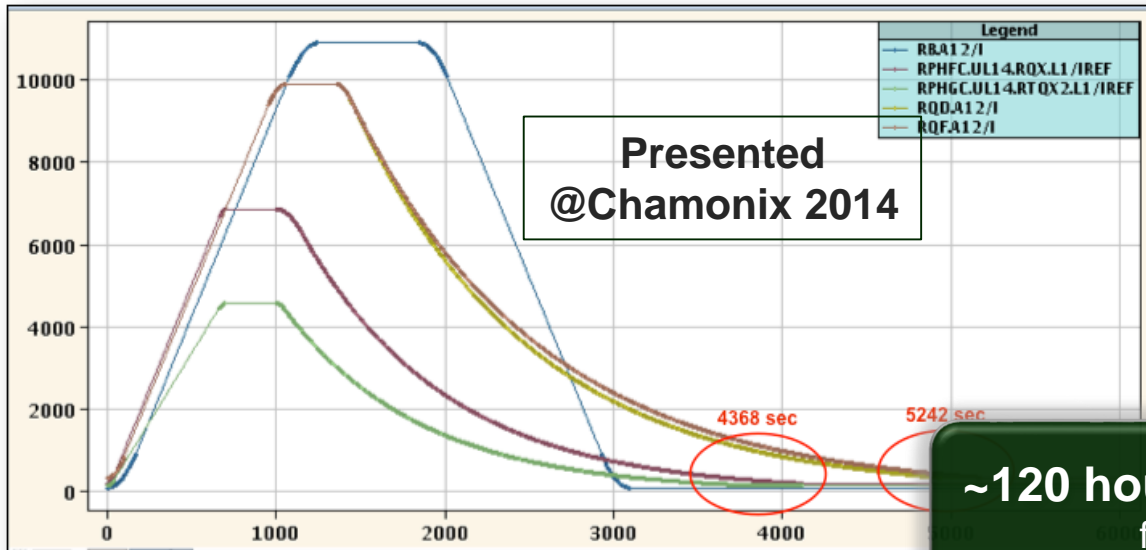

Where can we gain **time**?

- ❑ **Injection** remains a phase where we spend much more time than the theoretical time. There are many reasons → to be improved in 2016.
- ❑ **Ramp and squeeze** are highly optimized – clockwork. We can only gain by combining ramp & squeeze: we will squeeze to 3m during the 2016 ramp.
- ❑ **Adjust** (going into collision): we could gain 5-10 mins on average. Discussions with LPC & experiments initiated to move faster to stable beams.

✧ **230 pre-cycles** of whole LHC done in 2015

*The pre-cycle & rampdown strategy was already adapted in 2015 as compared to run 1.*

**~120 hours (5 days) gained in 2015** from precycle&rampdown

## We cannot do without pre-cycle...

- ❑ ...but in 2016 another gain of **4-5 days** could be achieved by pre-cycling to **3.5 TeV** (and not 6.5 to TeV).
- ❑ This has consequences for injection (different fields after ramp-down or pre-cycle): **will be tested during beam commissioning** (trivial to back off).

- ❑ mDQQBS radiation induced failures.

- *No safety, repair during TS2.*

- ❑ TDI absorber failures > 400 deg.

- *Limit on no. injected bunches.*

- ❑ BLM threshold changes

- *Weigh unnecessary UFO dumps vs protection.*

- ❑ Doublet beam for scrubbing

- *Issues with interlock BPMs.*

- ❑ Beam dump block N2 pressure.

- *Discovered a weakness in the surveillance of the dump.*

Efficient and fast reactions, mitigations were put in place.

No problems during the intensity ramp up of the LHC in 2015.

## Beam dump causes 2015 versus 2012 above injection

2012 (536)

2015 (442)

- False beam Dumps by Machine Protection Systems stable (LBDS, PIC, BLM, BIC, SIS, QPS, FMCM):

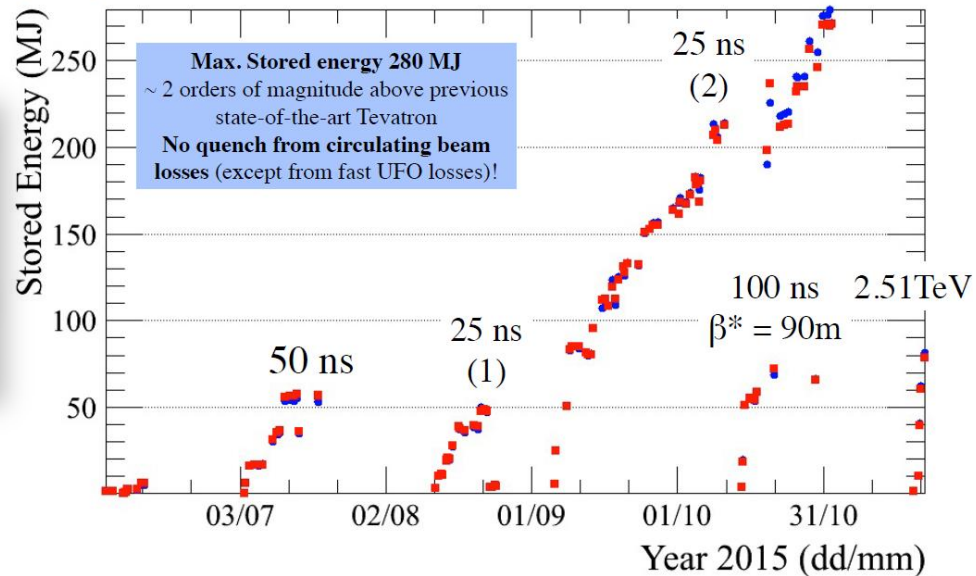

**14 % in 2012 → 13 % in 2015: OK**

- ❑ Intensity ramp up in 2016 is likely to be similar than in 2015. In particular because of the smaller  $b^*$  of 40-50 cm:
  - *Much less aperture and margins,*
  - *Potential instabilities.*
- ❑ Initial ramp up to ~500 bunches cannot go much faster as we need time & fills to monitor the evolution and performance. One or two fills are not sufficient...
- ❑ From 500-1000 bunches, ramp up speed is generally defined by our capacity to handle e-cloud, beam stability, etc.
  - *Duration at high intensity is very likely not defined by MP, see 2012 and 2015 !*

The stored energy reached 270 MJ (360 MJ design) at 6.5 TeV – still no quench of a magnet due to cleaning losses.

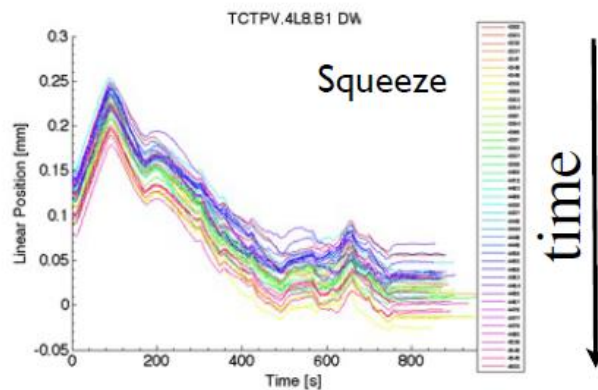

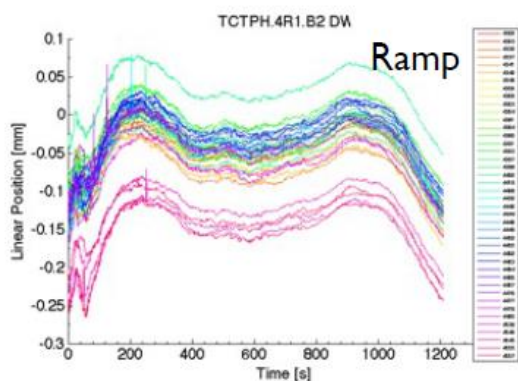

2015 Run

Remarkable cleaning stability with 6.5TeV beam, thanks to the excellent machine reproducibility

= magnets, collimators, instrumentation, feedbacks

- Thanks to experience and automation the collimation setup and validation time was reduced by more than a **factor 4** since 2010.
- In 2015 80% of the collimators were aligned with BLMs, 20% with BPMs.

- Systematic orbit offsets in the collimators during the cycle (ramp, squeeze) will be corrected in 2016...
- Preparing to interlock the beam position in collimators at lowest  $\beta^*$ .

- The **single-bunch threshold** has been measured: nominal bunch intensity ( $1.1E11$  p) will be unstable below 0.85 ns with 10 MV RF.
- No coupled bunch instability was observed so far (2244b).
- To avoid bunch instabilities at the end of long fill due to shrinking from synch. radiation, the bunch length should be controlled (blow-up) during the fills – also a demand by some experiments (keep bunch length ~ constant).
- Tests were performed in 2015, to be made operational in 2016.

*Stability threshold*

$N_b$ (p per bunch) in E11	Stability threshold		
	10 MV	12 MV	14 MV
0.9 ns	1.18	1.41	1.65
1 ns	2.00	2.40	2.80
1.1 ns	3.22	3.87	4.51
1.2 ns	4.98	5.97	6.97
1.3 ns	7.43	8.91	10.4

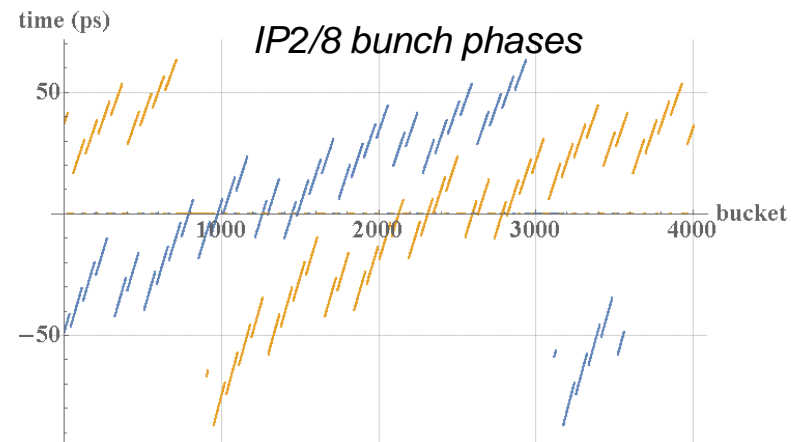

- So far we have operated the LHC RF with full compensation of the transient beam loading in the cavities:  $V(t) = V_0$
- As a consequence beam-loading is invisible in amplitude, barely visible in phase (0.5 deg pk-pk) → **large power transients for the klystrons !**

Nov 2<sup>nd</sup>, 2015.  
Fill 4565. 2244 b.  
Cav4B1

- An alternative scheme keeps the voltage constant over a turn with a modulation of the phase → limits the power transients in the klystrons.
  - But it induces phase modulation of the bunches.
- Scheme to be tried soon...

- The LHC cannot be operated at high intensity without transverse damper ADT (fast bbb feedback system) – key system.
- The ADT is continuously improved, one major item is better diagnostics of the damper itself, the other one is the capability of providing bbb and tbt data over all bunches.

- It are not just the dipoles that quenched, but with the exception of some circuits that are limited in current, the situation is good.

		Nr. of magnets	2008	2009	Feb 2013	2014/5
<i>no. quenches</i>	60 A	752	2	3	0	<b>23</b>
	80-120 A	1476	37	38	4	<b>23</b>
	120 A triplet	40	0	1	0	<b>4</b>
	600 A	6518	140	0	77	<b>154</b>
	600 A triplet	56	26	4	14	<b>37</b>
	IPD	18	13	0	10	<b>4</b>
	IPQ	220	49	0	68	<b>31</b>
	IT mains	32	0	0	4	<b>2</b>
	RQ	794	2	0	0	<b>2</b>
	RB	1232	30	0	0	<b>175</b>

- During the 2015 run we have lost a sextupole spool circuit of B2 in S78 – short circuit (when mains are powered).
  - *Backup: spread the correction over the 7 other sectors (non-local).*

- A new model for the quench behaviour was established from the 2015 quench campaign. The new estimates for the # quenches to reach 7 TeV :
  - ~270 first quenches to go !

Best estimate for 7 TeV (first q. only)					Done	to do
sector	1000	2000	3000	total		
12	3	19	7	28	7	21
23	3	12	30	44	17	27
34	2	16	22	40	15	25
45	2	9	62	73	49	24
56	1	8	63	73	16	57
67	3	7	46	56	20	36
78	3	24	46	72	21	51
81	3	5	50	58	28	30
LHC	20	100	325	445	173	272

- The data are compatible with a scenario where after each warm-up we re-start in the same conditions than at the beginning of the previous campaign.
- We could probe the predictions by pushing ~2 sectors towards 7 TeV (future powering campaign).

Mera peak, 6.5 km high

Kun, 7 km high
