# FLUKA Geometry

---

FLUKA Advanced Course

---

# Contents

- combinatorial geometry and format recalls
- bodies
  - generic quadric
  - transformations and rotation concepts
- regions
  - operators
  - problems and hints
  - parentheses
- lattice
- ancillary core routines
- dynamic objects
- voxels (see dedicated tutorial on Medical Application on Friday)

# Introduction

## Principle of Combinatorial Geometry

Basic objects called **bodies** (such as cylinders, spheres, parallelepipeds, etc.) are combined to form more complex objects called **regions**

This combination is done using Boolean operations:  
**union, intersection, and subtraction**

1 complex  
object

3 basic  
objects

# Basic Concepts

Four concepts are fundamental in the FLUKA CG:

- **Bodies** - basic convex objects + infinite planes & infinite cylinders + generic quadric
- **Zones** - sub-region defined only with intersection and subtraction of bodies (used internally)
- **Regions** - are defined as boolean operations of bodies (union of zones)
- **Lattices** - duplication of existing regions (translated & rotated)

# Geometry input format

- The input file format for the geometry is different from the one adopted anywhere else in FLUKA (i.e. the number and length of the input fields is different)
- Different formats can be used (due to backward compatibility)
  - **Fixed format**
    - ◆ Alignment is mandatory
    - ◆ Bodies and regions are identified by numbers (rather than names), this makes geometry editing more difficult
  - **Name based format**
    - ◆ **It is the recommended format**
    - ◆ **It is NOT the default!**

# Name based format

It has many advantages, the main are:

- input parameter alignment is not necessary
- bodies and regions are identified by **names**
- possible to edit the input sequence without affecting the region description (e.g. inserting a new body)
- **parentheses can be used to perform complex Boolean operations** in the description of regions.

**Name based format** input is used for both body and region

It is activated

either by a **GLOBAL** command at the beginning of the input file  
or putting **SDUM = COMBNAME** in the **GEOBEGIN** card

<b>GEOBEGIN</b>	Log: ▼ Inp: ▼	Acc: Out: ▼	Opt: ▼ Fmt: COMBNAME ▼
Title:			
*...+...1...+...2...+...3...+...4...+...5...+...6...+...7...+... <b>GEOBEGIN</b> 0 0			COMBNAME

# Input structure

FLUKA CG input must respect the following sequential order:

**GEOBEGIN** card

**VOXELS** card *(optional)*

Geometry title (and reading format options)

Body data

**\$Start\_**transformation *(optional)*

Body data

**\$End\_**transformation *(optional)*

Body data

**END** card *(automatically added by flair)*

Region data

**END** card *(automatically added by flair)*

**LATTICE** cards *(optional)*

Region volumes *(optionally requested by a flag in the  
Geometry title, used together with **SCORE**)*

**GEOEND** card

Cards having a \* in column 1 are treated as comments

# GEOBEGIN card

<b>GEOBEGIN</b>	Log: ▼ Inp: ▼	Acc: Out: ▼	Opt: ▼ Fmt: COMBNAME ▼
Title:			
*...+...1...+...2...+...3...+...4...+...5...+...6...+...7...+...*			
GEOBEGIN			COMBNAME
0	0		

WHAT(1) not used

WHAT(2) set accuracy parameter - **use with extreme care !**  
→ see next slide

WHAT(3) logical unit for the geometry input.  
Geometry input can be read from file; should be >20.0

WHAT(4) logical unit for the geometry output  
Log feature; should be >20.0 ; Default is standard output

WHAT(5) Parenthesis optimization level

WHAT(6) not used

SDUM **COMBNAME** or **COMBINAT**

**COMBNAME** selects name based format, **COMBINAT** fixed format

Default: **COMBINAT** (!)

Is overwritten by **WHAT(5)** of a possible **GLOBAL** card

# Tracking accuracy

- ❑ FLUKA uses systematically double precision mathematic (i.e. 16 significant digits)
- ❑ GEOBEGIN's  $WHAT(2) * 10^{-6}$  cm is the *absolute accuracy (AA)* requested for tracking and boundary identification
- ❑ The *relative accuracy (RA)* achievable in double precision is of the order of  $10^{-14}$ - $10^{-15}$
- ❑  $AA$  should be larger than  $RA * L$ , being  $L$  the largest coordinate value in the considered problem, i.e. the whole geometry size (The outer blackhole shell containing the system does not count)
- ❑ From FLUKA2011, instead of giving  $WHAT(2)$  the past default value of 0.0001, the code guesses  $L$  from the size of the second largest body in the geometry and sets  $WHAT(2)$  accordingly. Its value is reported in the output file and, if needed, can be retuned by the user.

# Bodies

- Each body divides the space into two domains **inside** and **outside**. The **outside** part is pointed to by the **normal** on the surface.
- 3-character code of available bodies:
  - **RPP**: Rectangular parallelepiped
  - **SPH**: Sphere
  - **XYP, XZP, YZP**: Infinite half space delimited by a coordinate plane
  - **PLA**: Generic infinite half-space
  - **XCC, YCC, ZCC**: Infinite circular cylinder, parallel to coordinate axis
  - **XEC, YEC, ZEC**: Infinite elliptical cylinder, parallel to coordinate axis
  - **RCC**: Right circular cylinder
  - **REC**: Right elliptical cylinder
  - **TRC**: Truncated right angle cone
  - **ELL**: Ellipsoid of revolution
  - **QUA**: Generic quadric surface
- Other bodies **ARB, RAW, WED, BOX**
  - **don't use them**, they cause sometimes rounding problems

# Important Notes

- Whenever it is possible, the following bodies should be preferred:

PLA, RPP, SPH, XCC, YCC, ZCC,  
XEC, YEC, ZEC, XYP, XZP, YZP, QUA

These make tracking faster, since for them extra coding ensures that unnecessary boundary intersection calculations are avoided when the length of the next step is smaller than the distance to any boundary of the current **region**.

- Always **use as many digits as possible** in the definition of the body parameters, particularly for body heights (RCC, REC), and for direction cosines of bodies with slant surfaces.

The free format [or the high-accuracy fixed format] should always be used in these cases.

# Bodies input

The input for each **body** consists of:

- the 3-letter code indicating the body type (RPP, ZCC...)
- a unique "**body name**" (alphanumeric identifier, 8 character maximum, **case sensitive**)
- a set of geometrical quantities defining the body

Different items can extend over as many lines as needed  
(Maximum 132 characters per line accepted)

Different items have to be separated by **one or more blanks**,  
or by one of the separators **, / ; :**

**All values are in cm!**

# Generic quadric: QUA

A **QUA** is the most generic quadric surface

It is defined by 10 coefficients in the **following order**:

$$\mathbf{A}_{xx} \quad \mathbf{A}_{yy} \quad \mathbf{A}_{zz} \quad \mathbf{A}_{xy} \quad \mathbf{A}_{xz} \quad \mathbf{A}_{yz} \quad \mathbf{A}_x \quad \mathbf{A}_y \quad \mathbf{A}_z \quad \mathbf{A}_0$$

corresponding to the equation

$$\mathbf{A}_{xx} x^2 + \mathbf{A}_{yy} y^2 + \mathbf{A}_{zz} z^2 + \mathbf{A}_{xy} xy + \mathbf{A}_{xz} xz + \mathbf{A}_{yz} yz + \mathbf{A}_x x + \mathbf{A}_y y + \mathbf{A}_z z + \mathbf{A}_0 = 0$$

or  $[x \quad y \quad z \quad 1]$   $\begin{bmatrix} \mathbf{A}_{xx} & \mathbf{A}_{xy}/2 & \mathbf{A}_{xz}/2 & \mathbf{A}_x/2 \\ \mathbf{A}_{xy}/2 & \mathbf{A}_{yy} & \mathbf{A}_{yz}/2 & \mathbf{A}_y/2 \\ \mathbf{A}_{xz}/2 & \mathbf{A}_{yz}/2 & \mathbf{A}_{zz} & \mathbf{A}_z/2 \\ \mathbf{A}_x/2 & \mathbf{A}_y/2 & \mathbf{A}_z/2 & \mathbf{A}_0 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} = 0$  i.e.  $\mathbf{r}^T \mathbf{M}_{\text{QUA}} \mathbf{r} = 0$

For example:

QUA EllHyper 0.25 1.0 -4.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 -1  
is an elliptic hyperboloid with axis equal to z

QUA Cylinder 0.5 1.0 0.5 0.0 1.0 0.0 0.0 0.0 0.0 -4.0  
is an infinite circular cylinder of radius 2 with axis  $\{z=-x, y=0\}$   
(i.e. at  $-45^\circ$  on the xz plane)

QUA EllParab 0.25 1.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 -1.0 0.0  
is an elliptic paraboloid with axis equal to z

# Geometry directives

Special commands enclosing body definition:

`$Start_xxx`

.....

`$End_xxx`

where "xxx" stands for  
"expansion", "translat" or "transform"

They provide respectively a coordinate **expansion/reduction**, a coordinate **translation** or a coordinate **roto-translation** of the bodies embedded between the starting and the ending directive lines.

<code>\$start_transform</code>	Trans:	▼		
<code>\$end_transform</code>				
<code>\$start_expansion</code>	f:			
<code>\$end_expansion</code>				
<code>\$start_translat</code>	dx:	dy:	dz:	
<code>\$end_translat</code>				

# Directives in geometry: expansion/reduction

➤ `$Start_expansion ... $End_expansion`

it provides a coordinate expansion (reduction) factor **f** for all bodies embedded within the directive

`$Start_expansion 10.0`

`SPH Sphere 5.0 7.0 8.0 50.0`

`$End_expansion`

<code>\$start_expansion</code>	f:10.0		
<code>SPH Sphere</code>	x:5.0 R:50.0	y:7.0	z:8.0
<code>\$end_expansion</code>			

transforms a sphere of radius 50 centered in (+5,+7,+8) into a sphere of radius 500 centered in (+50,+70,+80)

Putting the body in its quadric form

$$A_{xx} x^2 + A_{yy} y^2 + A_{zz} z^2 + A_{xy} xy + A_{xz} xz + A_{yz} yz + A_x x + A_y y + A_z z + A_0 = 0$$

$$\text{or } \begin{bmatrix} x & y & z & 1 \end{bmatrix} \begin{bmatrix} A_{xx} & A_{xy}/2 & A_{xz}/2 & A_x/2 \\ A_{xy}/2 & A_{yy} & A_{yz}/2 & A_y/2 \\ A_{xz}/2 & A_{yz}/2 & A_{zz} & A_z/2 \\ A_x/2 & A_y/2 & A_z/2 & A_0 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} = 0 \quad \text{i.e. } \mathbf{r}^T \mathbf{M}_{\text{QUA}} \mathbf{r} = 0$$

the expansion/reduction matrix is  $T =$

$$\begin{bmatrix} f & 0 & 0 & 0 \\ 0 & f & 0 & 0 \\ 0 & 0 & f & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

and the transformed body equation is  $\mathbf{r}^T (\mathbf{T}^{-1})^T \mathbf{M}_{\text{QUA}} \mathbf{T}^{-1} \mathbf{r} = 0$

# Directives in geometry: translation

➤ `$Start_translat ... $End_translat`

it provides a coordinate translation  $S_x, S_y, S_z$  for all bodies embedded within the directive

```
$Start_translat -5.0 -7.0 -8.0
```

```
SPH Sphere 5.0 7.0 8.0 50.0
```

```
$End_translat
```

transforms a sphere of radius 50 centered in (+5,+7,+8)  
into a sphere of radius 50 centered in (0,0,0)

<code>\$start_translat</code>	dx: -5.0	dy: -7.0	dz: -8.0
 <code>SPH Sphere</code>	x: 5.0 R: 50.0	y: 7.0	z: 8.0
<code>\$end_translat</code>			

the translation matrix is  $T =$

$$\begin{bmatrix} 1 & 0 & 0 & S_x \\ 0 & 1 & 0 & S_y \\ 0 & 0 & 1 & S_z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

# Directives in geometry: roto-translation

➤ `$Start_transform ... $End_transform`

it applies a pre-defined (via **ROT-DEFI**) roto-translation to all bodies embedded within the directive

```
ROT-DEFI , 201.0, 0., +116.5650511770780, 0., 0., 0., cylrot
```

```
$Start_transform cylrot
```

```
QUA Cylinder 0.5 1.0 0.5 0.0 1.0 0.0 0.0 0.0 0.0 -4.0
```

```
$End_transform
```

transforms an infinite circular cylinder of radius 2 with axis  $\{x=-z, y=0\}$  into an infinite circular cylinder of radius 2 with axis  $\{x=z/3, y=0\}$  (**clockwise rotation**)

the roto-translation matrix is  $T =$

$$\begin{bmatrix} R & S_x \\ & S_y \\ & S_z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$T^{-1} = \begin{bmatrix} & -(R^{-1}S)_x \\ R^{-1} & -(R^{-1}S)_y \\ & -(R^{-1}S)_z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

- it allows to rotate a **RPP** avoiding the use of the deprecated **BOX** !

- note that also the **inverse** transformation can be used  $T^{-1}$

```
$Start_transform -cylrot
```

# ROT-DEFIni

The **ROT-DEFIni** card defines roto-translations that can be applied, in addition to bodies, to i. **USRBIN** & **EVENTBIN** and ii. **LATTICE**. It transforms the position of the tracked particle i. before scoring with respect to the defined binning or ii. into the prototype with the order:

- First applies the translation
- followed by the rotation on the azimuthal angle
- and finally by the rotation on the polar angle.

$$\mathbf{X}_{\text{new}} = \mathbf{M}_{\text{polar}} \times \mathbf{M}_{\text{az}} \times (\mathbf{X} + \mathbf{T})$$

**WHAT(1):** assigns a transformation index and the corresponding rotation axis  
**I + J \* 100** or **I \* 1000 + J**

I = index of rotation (WARNING: NOTE THE SWAP OF VARIABLES)

J = rotation with respect to axis (1=X, 2=Y, 3=Z)

**WHAT(2):** Polar angle of the rotation ( $0 \leq \vartheta \leq 180^\circ$  degrees)

**WHAT(3):** Azimuthal angle of the rotation ( $-180 \leq \varphi \leq 180^\circ$  degrees)

**WHAT(4), WHAT(5), WHAT(6)** = X, Y, Z offset for the translation

**SDUM:** Optional (but recommended) name for the transformation

---

**ROT-DEFI**

Id: 1

Axis: Z ▼

Name: 1tra

Polar: 0.0

Azm:

Δx:

Δy:

Δz: -10.0

# Identifying rotation angles

Let's define the orientation of a body in the space by a system of 3 orthogonal vectors  $\mathbf{i}'$ ,  $\mathbf{j}'$ ,  $\mathbf{k}'$ , whose coordinates are expressed with respect to the fixed reference frame  $X, Y, Z$

Then  $[\mathbf{i}' \ \mathbf{j}' \ \mathbf{k}'] = \begin{bmatrix} c_1 c_3 - c_2 s_1 s_3 & -c_1 s_3 - c_3 c_2 s_1 & s_2 s_1 \\ c_2 c_1 s_3 + c_3 s_1 & c_1 c_2 c_3 - s_1 s_3 & -c_1 s_2 \\ s_3 s_2 & c_3 s_2 & c_2 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}$  (in the ZXZ convention)

where  $c_1 = \cos(\psi)$   $c_2 = \cos(\theta)$   $c_3 = \cos(\Phi)$   $s_1 = \sin(\psi)$   $s_2 = \sin(\theta)$   $s_3 = \sin(\Phi)$

here  $\Phi = 45^\circ$   $\theta = 30^\circ$   $\psi = -60^\circ$

The obtained Euler angles can be input as azimuthal angle of three consecutive rotations (**ROT-DEFI**)

# Directives in geometry: warnings

- `$Start_expansion` and `$Start_translat` are applied when reading the geometry → no CPU penalty (the concerned bodies are transformed once for ever at initialization)

`$Start_transform` is applied runtime → some CPU penalty

- One can **nest** the different directives (*at most one per type!*) but, no matter the input order, the adopted sequence is always the following:

```
$Start_transform StupiRot
```

```
$Start_translat -5.0 -7.0 -8.0
```

```
$Start_expansion 10.0
```

```
QUA WhatIsIt +1.0 +1.0 +1.0 0.0 0.0 0.0 -10.0 -14.0 -16.0 -2362.0
```

```
$End_expansion
```

```
$End_translat
```

```
$End_transform
```

- Directives are not case sensitive (whereas roto-translation names are)

# Regions (I)

Input for each region starts on a new line and extends on as many continuation lines as are needed. It is of the form:

*REGNAME NAZ boolean-zone-expression | boolean-zone-expression | ...*

- "*boolean-zone-expression*" is a sequence of one or more **body** names preceded by the operators **+** (intersection) or **−** (complement or subtraction). Several **zone** expressions can be combined by the union operator **|**. (A single boolean-zone-expression is admitted).

The operator precedence sequence is: first **parentheses** (see later), then **+** and **−**, last **|**.

- *REGNAME* is the **region name** (an arbitrary unique alphanumeric character string chosen by the user). The region name must begin by an alphabetical character and must not be longer than 8 characters.

## Regions (II)

- **NAZ** (Number of **A**djacent **Z**ones) is a rough estimate of the number of zones a particle can enter when leaving the current region zones (5 by default). What actually matters is the NAZ sum over all regions, defining the size of the *contiguity list*
- While tracking, the program searches in the contiguity list for the neighbor zones of each zone. If the zone is not yet in the list, the whole geometry is scanned and it is added to the list with its neighbor zones
- When the NAZ limit is reached (i.e. the list is full) the code prints a warning: GEOMETRY SEARCH ARRAY FULL. This is not lethal: the calculation continues but with a reduced efficiency
- If you have more than 1000 regions, you must issue a **GLOBAL** card putting in **WHAT(1)** a higher limit (not beyond 10000)

# Operators

**Regions** are defined as **combinations of bodies** obtained by boolean operations:

	Union	Subtraction	Intersection
<b>Named based</b>		−	+
<i>Fixed</i>	<i>OR</i>	−	+
Mathematically	$\cup$	−	$\cap$

**Regions** are not necessarily simply connected (they can be made as the union of two or more non contiguous or partially **overlapping zones**) but must be of **homogeneous material composition**. **Zones** must be finite.

# Regions Boolean expression

- **zones** are defined by intersections and/or subtraction of **bodies**, each body being preceded by its + or - sign (+ in the first body not required)
- | (OR) operators are used to join **zones**
- In evaluating the expressions, the highest operator precedence is given to parentheses, followed by +, - and the | operator
- Parentheses are available in name based format (use with care!)
- If one line is not sufficient, any number of continuation lines can be added
- Blanks are ignored

# Meaning of + and - operators

If a **body** number (or name) appears in a **zone** description preceded by a + operator, it means that the **zone** being described is **wholly contained inside** the **body**.

If a **body** number appears in a **zone** description preceded by a - operator, it means that the **zone** being described is **wholly outside** the **body**.

**Zones** must be finite: normally in the description of each **zone** and hence of each **region** the symbol + must appear at least once.

# Meaning of the | (OR) operator

The | (or OR) operator is used as a Boolean **union** operator in order to combine **zones** (**sub regions** partially overlapping or not).

**Zones** are formed as body intersections or subtractions as previously explained

The **regions** are formed by the union of these **zones**.

Examples:

```
Ground 5 | +Body9 | +Body15 | +Body1 | +Body8 - Body2 | +Body8 - Body3
*          <- 1st -><- 2nd -><- 3rd -><----- 4th -----><----- 5th ---->
* (continuation line)
          | +Body8 +Body18 | +Body12 - Body10 - Body11 - Body13 - Body14
*          <----- 6th -----><----- 7th and last zone ----->
```

# Illustration of the + and - operators

# The Blackhole

To avoid infinite tracking the particles must be stopped somewhere. This has to be insured by the user by defining a region surrounding the geometry and assigning the material `BLCKHOLE` to it.

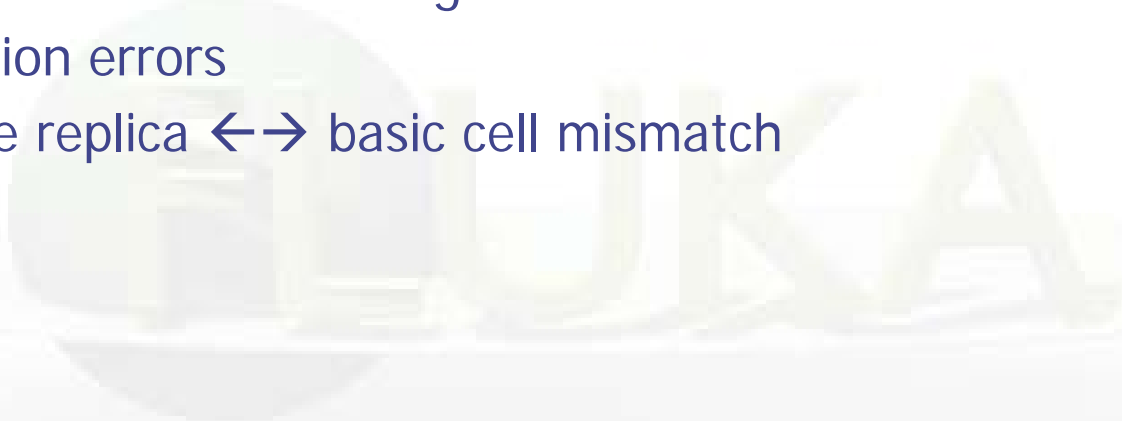

All particles that enter the blackhole are absorbed (they disappear and are flagged as escaping). Further blackhole regions can be defined by the user if necessary.

The blackhole is the outermost boundary of the geometry. Inside the blackhole region:

**Each point of space must belong to one and only one region!**

# Geometry Errors

- Problem space not enclosed by a black body region
- Never start a primary particle along a surface. You could get a geometry error even if the geometry is correct because FLUKA cannot determine the region
- Precision errors
- Lattice replica  $\leftrightarrow$  basic cell mismatch

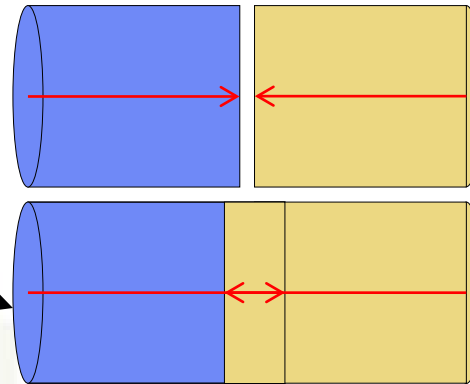

# Preventing precision errors

Ideal world

Computation world

**Avoid touching surfaces!**

When floating point operations are involved

- Use cutting planes instead

- Or force partial overlap of bodies

# Geometry error messages

During execution the code always needs to know the region where a particle is located at every step.

- The program will **stop** only if a particle's position **does not belong to any region**.  
It will issue an error message on the **.err** file with the particle position.
- **IMPORTANT!** It will **not stop** if a particle's position **belongs to more than one region**. It will accept the first region it finds but **results will be unreliable!!**

# Debugging tools

- **GEOEND** card with the **DEBUG** option
- Error messages during simulation in the **.err** file
- Geometry plotting by Flair  
(automatically invoking the **PLOTGEOM** card)
- **FLAIR Geometry Editor** (very powerful! See the dedicated lecture)
- SimpleGeo

# Native debugger (I)

**GEOEND** card activates the FLUKA geometry debugger.

Detects both undefined or multiple defined points in a selected X,Y,Z mesh

Two cards are needed

First card

WHAT(1)=X<sub>max</sub>

WHAT(4)=X<sub>min</sub>

SDUM = DEBUG

WHAT(2)=Y<sub>max</sub>

WHAT(5)=Y<sub>min</sub>

WHAT(3)=Z<sub>max</sub>

WHAT(6)=Z<sub>min</sub>

Second Card

WHAT(1)=Nx

SDUM = &

WHAT(2)=Ny

WHAT(3)=Nz

```
GEOEND Xmax Ymax Zmax Xmin Ymin Zmin DEBUG
```

```
GEOEND Nx Ny Nz &
```

◆ GEOEND	DEBUG ▼			
	Xmin:	Xmax:		NX:
	Ymin:	Ymax:		NY:
	Zmin:	Zmax:		NZ:

## WARNING!

The program stops if too many errors are found  
A message will be issued on the output unit

# Native debugger (II)

- If **no error** is found, no **.err** file will be created.
- **REMINDER**: If the debugger doesn't find any error it doesn't mean that the geometry is error free!
- Errors will be listed in the **.err** file in the form:
  - \*\*\*\* Lookdb: Geometry error found \*\*\*\*
  - \*\*\*\* The point: -637.623762 -244.554455 -96.039604 \*\*\*\*
  - Point is contained in more than one region
    - \*\*\*\* is contained in more than 1 region \*\*\*\*
    - \*\*\*\* (regions: 6 7) \*\*\*\*
  - Not contained in any region
    - \*\*\*\* is not contained in any region
- Exploit the geometry symmetry asking for 2D scans on planes
- Scan only the problematic areas
- Adopt a step length that prevents from ending up on “special” points (i.e. boundaries)

# User optimization in region definition

A zone involving many bodies increases the tracking time, since the exiting conditions imply a respective number of checks

1731 holes

one zone with MANY bodies:  
large CPU time!

slices with <50 holes

many zones with much less  
bodies each: significant benefit

...ideally large zones (far boundaries) with few bodies (!)

prefer overlapping zones

# Parentheses

Parentheses are grouping together combinations of bodies. Parentheses can be used in **name based format** only.

Examples:

\*...+... 1...+... 2...+... 3...+... 4...+... 5...+... 6...+... 7...

\* Subtract from body2 regions regR03, regR04, regR05

```
regV02 5 +body2 - (+body4 - body3)
          - (+body6 - body5 | +body8 - body7) - body9 - body10
regR03 5 +body4 - body3
regR04 5 +body6 - body5 | +body8 - body7
regR05 5 +body9 | +body10
```

**Nested parentheses** are supported, however:

- parentheses should be used with care since their expansion can generate a quickly diverging amount of terms.
- A partial optimization is performed on planes (aligned with the axes) and bounding boxes only

# Parenthesis Expansion (I)

- Parentheses expansion is **almost like** converting from **product of sums** to **sum of products**
- Product operators are: **+/-**, Sum operator: **|**
- The final result will be an expression in the normal form. Unions of **all possible combinations** of the bodies in the expression!
- Initially the code removes all repeated terms:  
$$A + A = A$$
$$A - A = \emptyset$$
$$\text{expA} | \text{expA} = \text{expA}$$

# Parenthesis Expansion (II)

**Geometrical optimization** can drastically reduce the number of zones

1. Elimination of same type of planes (XYP, XZP, YZP) inside a zone (product)
2. Optimization of zones based on the **bounding boxes** of the bodies.
  - **Infinite objects** have an **infinite bounding** box on some of the dimensions i.e. XYP, ZCC etc.
  - **PLANes** do not have a bounding box
  - For each zone after the expansion, if the intersection of the bounding boxes is empty the zone is discarded

# Online Parentheses Expansion

If the parentheses expansion (see previous slides) leads to too many terms, another algorithm based on Reverse Polish Notation and inline evaluation is used:

$$A - (B|C) + D \rightarrow A B C | - D +$$

The FLUKA geometry tracking algorithm was highly optimized with plenty of repeated inline operations

All terms have to be evaluated : More time consuming than evaluating a single zone

Performance penalty depending on the cases (reported from 10% to factor of 10 !)

# Lattice

FLUKA geometry has *replication* (lattice) capabilities

*Only one level is implemented* (no nested lattices are allowed)

- The user defines lattice positions in the geometry and provides transformation rules from the lattice to the prototype region:
  1. in the input with the ROT-DEFI card
  2. in a subroutine (`lattic.f`)

The lattice identification is available for scoring

Transformations include:

Translation, Rotation and Mirroring (the last only through routine).

**WARNING:**

Do not use **scaling or any deformation** of the coordinate system

# Lattice

- The regions which constitute the **elementary cell** (*prototype*) to be replicated, have to be defined in detail
- The **Lattices** (*replicas/containers*) have to be defined as “empty” regions in their correct location.  
**WARNING:** The lattice region should map exactly the outer surface definition of the elementary cell.
- The lattice regions are declared as such with a **LATTICE** card at the end of the geometry input
- In the **LATTICE** card, the user also **assigns lattice names/numbers to the lattices**. These names/numbers will identify the replicas in all FLUKA routines and scoring
- Several basic cells and associated lattices can be defined within the same geometry, one **LATTICE** card will be needed for each set
- **Non-replicas carry the lattice number 0**
- Lattices and plain regions can coexist in the same problem

# LATTICE card

After the Regions definition and before the GEOEND card the user can insert the LATTICE cards

- WHAT(1), WHAT(2), WHAT(3)  
Container region range (from, to, step)
- WHAT(4), WHAT(5), WHAT(6)  
Name/number(s) of the lattice(s)
- SDUM  
 blank to use the transformation from the lattic routine  
 ROT#nn to use a ROT-DEFI rotation/translation from input  
 name the same as above but identifying the roto-translation by the name assigned in the ROT-DEFI SDUM (any alphanumeric string you like)

## Example

```

LATTICE          Reg: TARGR1 ▼      to Reg: ▼      Step:
  Id: 1tra ▼      Lat: 1.0          to Lat: 1.0      Step: 1.0
*...+...1...+...2...+...3...+...4...+...5...+...6...+...7...+...
LATTICE          6.00000  19.00000          101.0000  114.00
  
```

Region # 6 to 19 are the "placeholders" for the first set replicas. We assign to them lattice numbers from 101 to 114

```

LATTICE          TARGR1          TargRep          1tra
TARGR1 is the container region using transformation 1tra
  
```

# Example

# Example

# Example

Prototype cell

Empty lattice cell

Final replica

# Transformation by input

- Rotations/Translations can be defined with the **ROT-DEFIni** card
- Can be assigned to a lattice by **name** or with **ROT#nnn** SDUM in the **LATTICE** card
- **ROT-DEFIni** cards can be consecutive (using the same **index** or **name**) to define complex transformations

## WARNING:

Since matrix multiplication is not commutative the **order** of the Rotation/Translation operations in 3D is important.

# Tips & Tricks

GEOBEGIN

```
...
RPP CollProt -540.0 -460.0 -20.0 20.0 100.0 300.0
$start_transform -rotColl *
RPP CollRepl -540.0 -460.0 -20.0 20.0 100.0 300.0
$end_transform
```

```
...
REG 5 CollRepl
```

```
...
LATTICE, REG,,,CollRepl,,,rotColl
GEOEND
```

```
ROT-DEFI, 1.0, 0.0, 0.0, 0.0, 0.0, -350.0, rotColl [A]
ROT-DEFI, 201.0, 0.0, -15.0, 0.0, 0.0, 0.0, rotColl [B]
ROT-DEFI, 1.0, 0.0, 0.0, -500.0, 0.0, 200.0, rotColl [C]
```

\* Remember: if  $R=CBA$ , then  $R^{-1}=A^{-1}B^{-1}C^{-1}$

# Tips & Tricks

- Always remember that the transformation must bring the container onto the prototype and not viceversa!
- You can always divide a transformation into many **ROT-DEFI** cards for easier manipulation.
- Rotations are always around the origin of the geometry, and not the center of the object.
  - To rotate an object, first translate the object to the origin of the axes
  - Perform the rotation
  - Move it by a final translation to the requested position.  
Of course with the inverse order since everything should apply to the replica
- In order to define the replica body, you can clone the body enclosing the prototype (assigning it a new name!) and apply to it the `$Start_transform` directive with the inverse of the respective **ROT-DEFI** transformation.

# Tips & Tricks

- The **Geometry transformation editor in flair** can read and write **ROT-DEFI** cards with the transformation requested
- An easy way of creating a replica and the associated transformation is the following:
  1. Select the body defining the outer cell of the prototype
  2. Clone it with (**Ctrl-D**) and change the name of the clones. Click on "**No**" when you are prompted to change all references to the original name.
  3. Open the Geometry transformation dialog (**Ctrl-T**)
  4. Enter the transformation of the object in the listbox
  5. Click on "**Transform**" to perform the transformation on the clone bodies
  6. Click on "**Invert**" button to invert the order of the transformation
  7. Enter a name on the "**ROT-DEFIni**" field and click "**Add to Input**" to create the **ROT-DEFIni** cards
  8. Now you have to create manually the needed **regions** and the **LATTICE** cards

# Numerical Precision

- Due to the nature of the floating point operations in CPU, even if the transformation looks correct the end result could be problematic

This small misalignment between lattice/transformation/prototype could lead to geometry errors

- Use as many digits as possible to describe correctly the prototype and lattice cells as well as the transformation.  
It is mandatory that the transformation applied to the container makes the latter EXACTLY corresponding to the prototype
- One can use a FREE and FIXED card before and after the ROT-DEFI to input more than 9 digits
- GEOBEGIN WHAT(2) allows to relax the accuracy in boundary identification (USE WITH CAUTION)

# Scoring with lattice

- Materials and other properties have to be assigned only to the regions constituting the prototype.
- In all (user) routines the **region number** refers to the corresponding one in the prototype.
- The **SCORE** summary in the **.out** file and the scoring by regions add together the contributions of the prototype region as well as of all its replicas!
- The lattice identity can be recovered runtime by the *lattice number*, as set in the **LATTICE** card, or available through the GEON2L routine if is defined by name
- In particular, the **LUSRBL** user routine allows to manage the scoring on lattices in the special **USRBIN/EVENTBIN** structure. 
- **USRBIN/EVENTBIN Cartesian and cylindrical meshes** are geometry independent and, if superimposed on replica containers (possibly profiting from applying to the binning the respective roto-translation via **ROTPRBIN**), naturally discriminate between different replicas.

# The USRBIN/EVENTBIN special binning

EVENTBIN or USRBIN with WHAT(1)=8 :

Special user-defined 3D binning. Two variables are discontinuous (e.g. region number), the third one is continuous, but not necessarily a space coordinate.

Variable	Type	Default	Override Routine
1 <sup>st</sup>	integer	region number	MUSRBR
2 <sup>nd</sup>	integer	lattice cell number	LUSRBL
3 <sup>rd</sup>	float	zero	FUSRBV

# The lattic routine (I)

- The actual transformation from the lattice cell (container) to the elementary cell (prototype) can also be provided through the **lattic** routine (if the **LATTICE SDUM** is left blank)

The use of the routine is mandatory for mirroring, and turns out to be highly preferable in the case of a lot of replicas placed according to a simple arithmetical rule (e.g. segmented detectors). Otherwise, the use of the **LATTICE** and **ROT-DEFI** cards does not imply any particular limitation and offers the possibility of being combined with the **\$Start\_transform** directive for the container definition (see later) and with the use of **ROTPRBIN** for the roto-translation of **USRBIN** scoring grids.

SUBROUTINE LATTIC ( XB, WB, DIST, SB, UB, IR, IRLTGG, IRLT, IFLAG )

- IRLTGG is the current **lattice number** (it can optionally be set in the **LATTICE** card), IR is the current **region number**
- XB,WB are vectors with the **current particle position and direction**
- the routine must give back SB,UB, i.e. **position and direction transported to the prototype**

The

ENTRY LATNOR ( UN, IRLTNO, IRLT )

must provide the transformation for a **vector** representing a direction (no translation), applying to boundary normals (UN is both the in and out vector; IRLTNO is the current **lattice number**)

# The lattic routine (II)

As an example, for the *10cm translation along z* shown in the previous slides:

```
LOGICAL LFIRST
DATA LFIRST / .TRUE. /
SAVE LFIRST, IREP
IF (LFIRST) THEN ! Find replica's lattice number
    CALL GEON2L('TargRep ', IREP, IRTLAT, IERR)
    LFIRST = .FALSE.
END IF
IF ( IRLTGG .EQ. IREP ) THEN
    SB (1) = XB (1)
    SB (2) = XB (2)
    SB (3) = XB (3) - 10.0D0
    UB (1) = WB (1)
    UB (2) = WB (2)
    UB (3) = WB (3)
END IF
```

And the **UN** transformation is the identity

More complex cases can involve reflections and rotations.

For instance, for a reflection around the z axis :

```
UN (1) = UN (1)
UN (2) = UN (2)
UN (3) = -UN (3)
```

# Accessing ancillary core routines

- To convert the lattice/region name of interest into the respective number (and vice versa), use the following routines – giving back IERR=0 in case of success - :

CHARACTER\*8 LATNAM

CALL **GEON2L**(LATNAM, **NLATT**, IRTLAT, IERR)                      Lattice Name to **Lattice #**

CALL **GEOL2N**(NLATT, LATNAM, IRTLAT, IERR)                      Lattice # to Lattice Name

IRTLAT is the returned index of the (possible) roto-translation associated

CHARACTER\*8 REGNAM

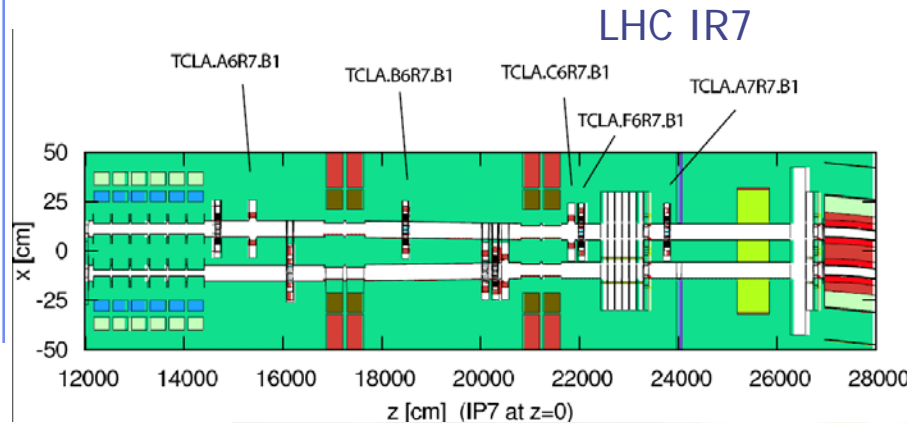

CALL **GEON2R**(REGNAM, **NREG**, IERR)                      Region Name to **Region #**

CALL **GEOR2N**(NREG, REGNAM, IERR)                      Region # to Region Name

- It is always a good practice to **call them only the first time** the calling user routine is accessed and save once for ever the needed pieces of info

# Object runtime readjustment (I)

- how to implement **collimator replicas** set at different apertures?

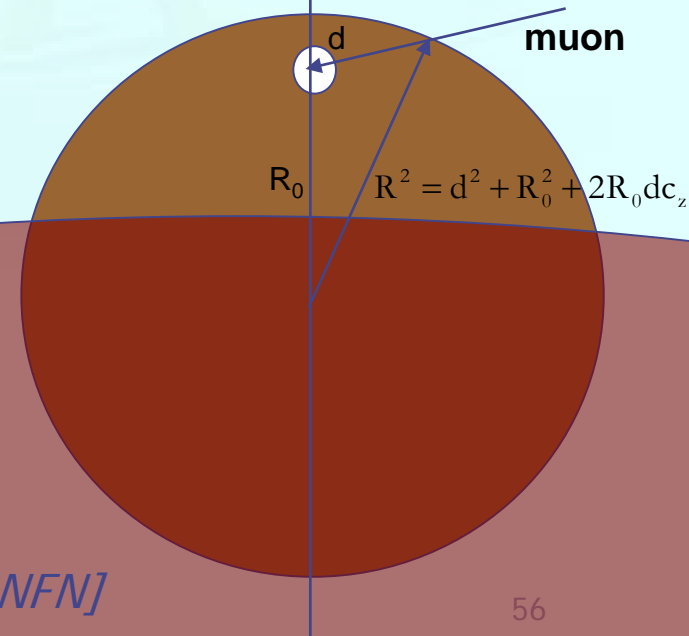

- how to implement the **actual rock thickness** according to the muon incident direction?
