

Multi-photon decays of the SM Higgs with ATLAS

Results at 7/8 TeV;
current work and
prospects at 13 TeV

How standard is h_{125} ?

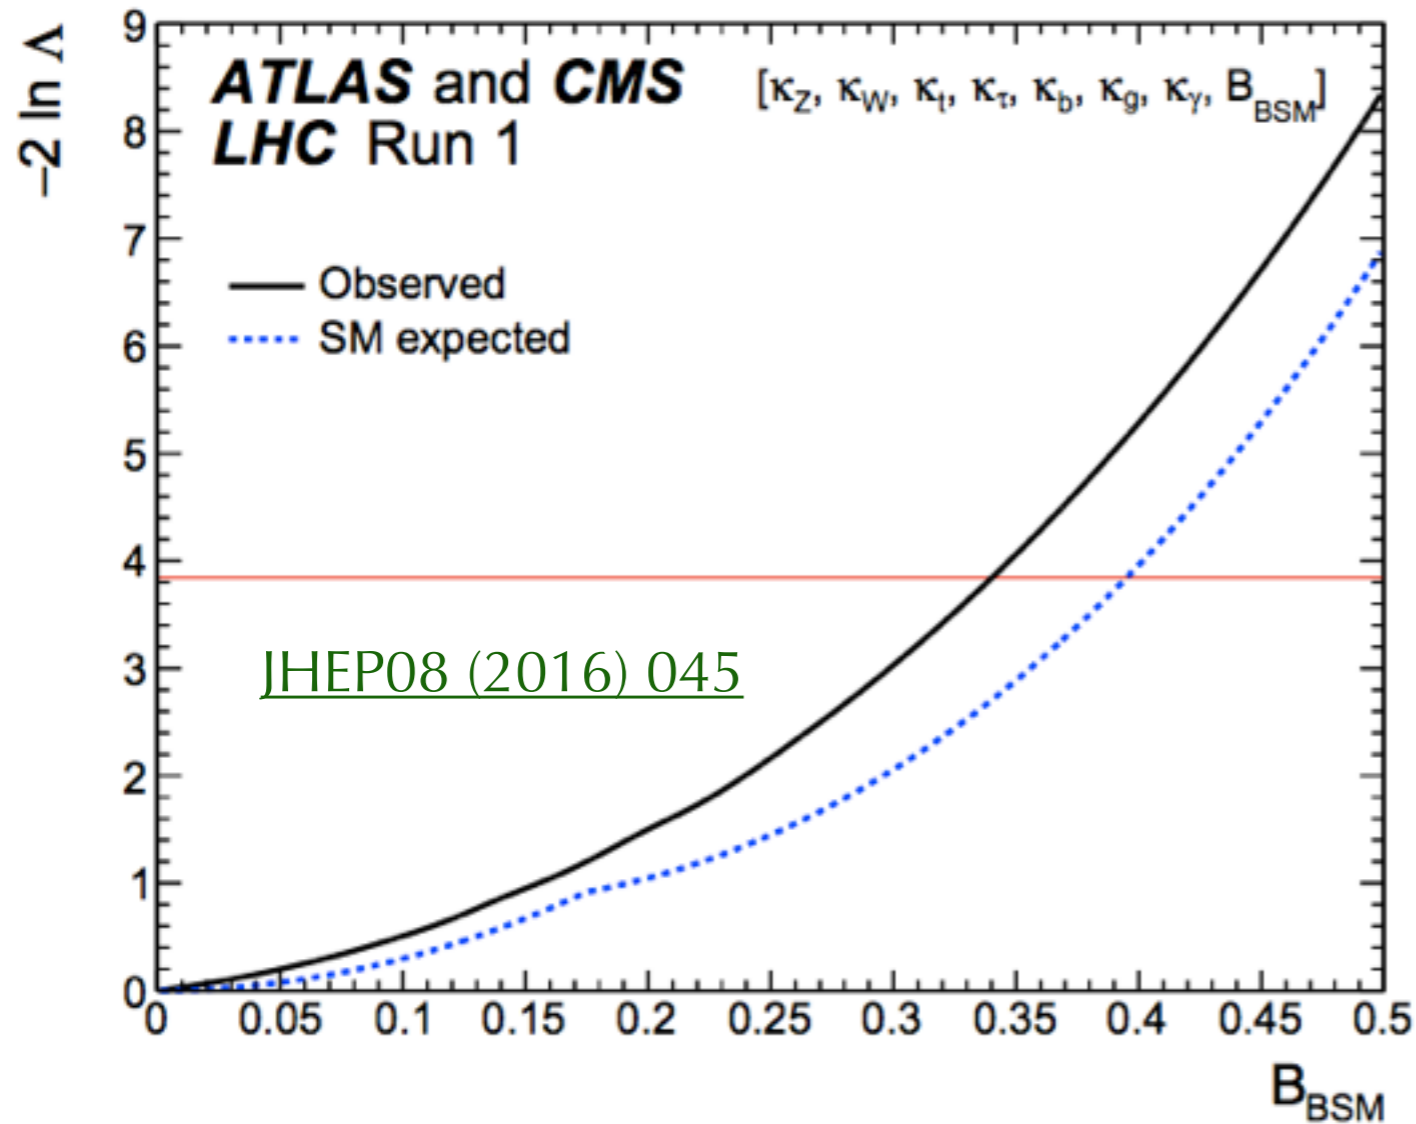

Photons as a discovery tool

Multi-photon decays of h_{125}

ATLAS results at 7 and 8 TeV

Current work at 13 TeV

Current (and future) LHC precision of measurements of couplings to SM particles leaves ample room for BSM physics

Some fits predict branching ratio of Higgs to invisible could be as large as 20 to 30%

- Robust tradition in ATLAS of searching for exotic decays of h125 and beyond:
Run 1: $2\mu 2\tau$, $Z_{(d)}Z_d \rightarrow 4L, 4\gamma$, lepton-jets
Run 2: $4b$ + many in the pipeline right now
- For many final states, difficult to access region with small m_a/m_H
==> fantastic places for new-signature R&D
- Here discussing multi-photon final states

SM

The bad news:
Small branching ratios

The good news:
Excellent isolated photon ID

BSM

The bad news:
Small branching ratios

The good news:
Excellent isolated photon ID...
...plus extremely good calorimeters

$\tan \beta = 0.5$, TYPE II

 $\Delta R \sim 2 * m_x / p_{T,x}$

Multi-photon signatures

Standard isolation calculated based on some fixed ΔR cone size (e.g., 0.4)

Real photons have narrower shower shapes than jets

Lots of extra energy in the cone \implies jet faking a photon

Distinguish photons from jets-faking-photons by requiring stringent isolation

\longrightarrow Straightforward for high mass diphoton resonance searches

\longrightarrow Challenge arises for low-mass resonances with low- p_T photons or highly boosted states

$$\Delta R \equiv \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$$

Two well-separated photons (!)

Two completely overlapping photons (!)

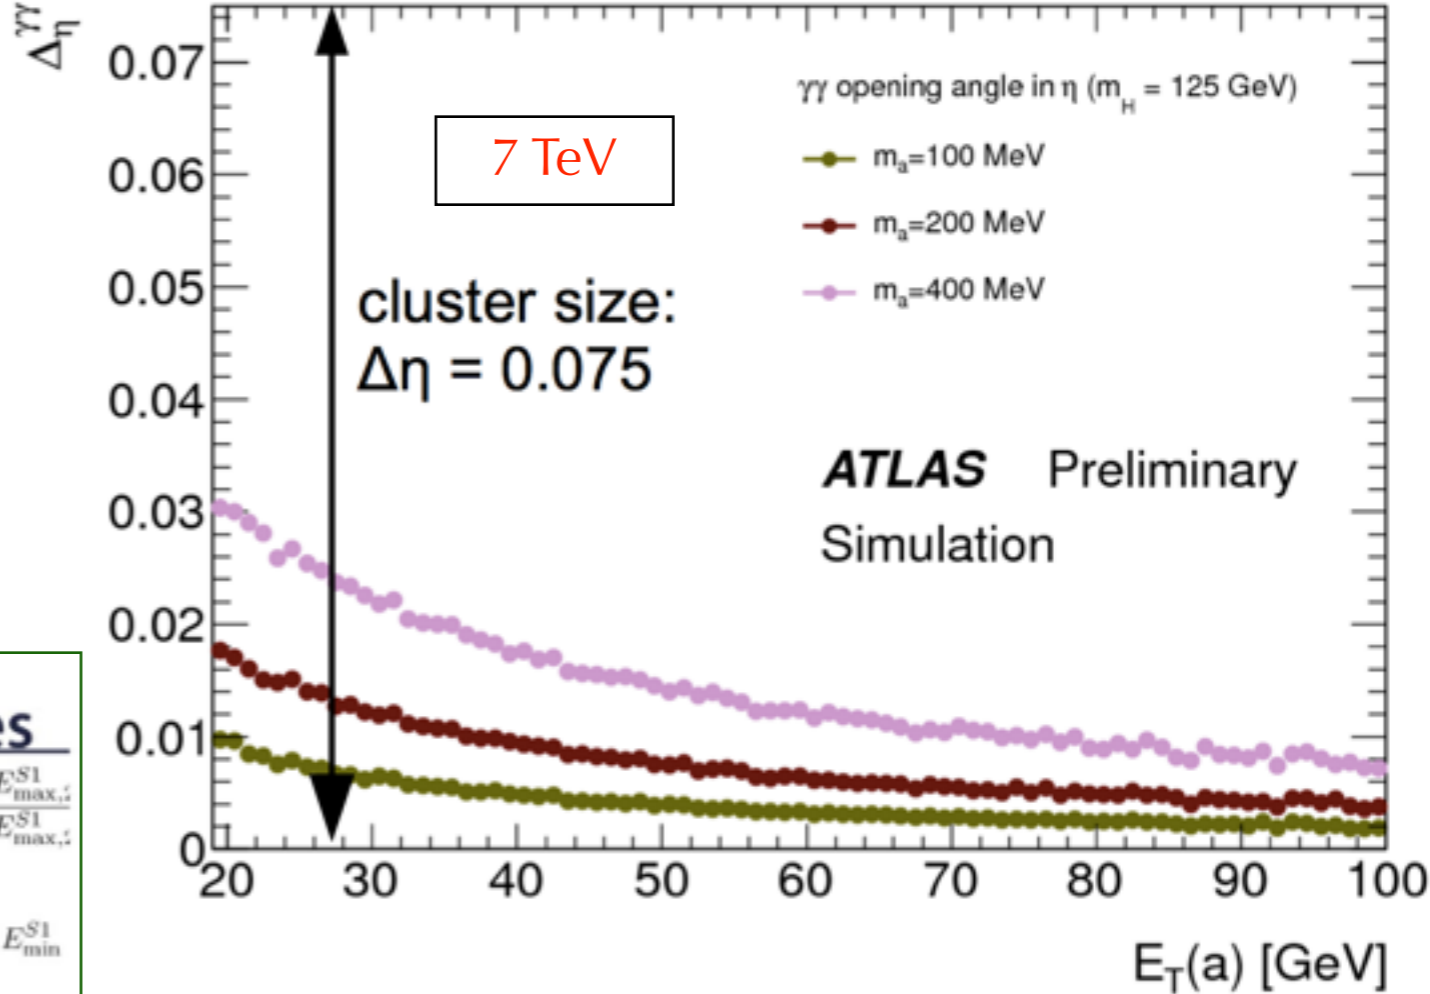

Two (or more) nearly-merged photons (?)

Sometimes referred to as "photon-jets"

ATLAS search for $h_{125} \rightarrow aa \rightarrow 4\gamma$

- Motivated by the slight excess seen in the h_{125} diphoton channel at the time
 - Looked at $100 \text{ MeV} < m_a < 400 \text{ MeV}$
- Separated single photons from two collimated photons with a custom photon ID

Variables and Position

| | Strips | 2nd | Had. |
|--------|------------------------------|------------------------|--------------------|
| Ratios | f_1, f_{side} | R_η^*, R_ϕ | R_{Had}^* |
| Widths | $w_{s,3}, w_{s,\text{tot}}$ | $w_{\eta,2}^*$ | - |
| Shapes | $\Delta E, E_{\text{ratio}}$ | * Used in PhotonLoose. | |

Shower Shapes

Energy Ratios

$R_\eta = \frac{E_{3 \times 7}^{S2}}{E_{7 \times 7}^{S2}}$

$R_\phi = \frac{E_{3 \times 3}^{S2}}{E_{3 \times 7}^{S2}}$

$R_{\text{Had}} = \frac{E_T^{\text{Had}}}{E_T}$

$f_1 = \frac{E_{S1}}{E_{\text{Tot}}}$

$f_{\text{side}} = \frac{E_7^{S1} - E_3^{S1}}{E_3^{S1}}$

Widths

$w_{\eta,2} = \sqrt{\frac{\sum E_i \eta_i^2}{\sum E_i} - \left(\frac{\sum E_i \eta_i}{\sum E_i}\right)^2}$

Width in a 3×5 ($\Delta\eta \times \Delta\phi$) region of cells in the second layer.

$w_s = \sqrt{\frac{\sum E_i (i - i_{\text{max}})^2}{\sum E_i}}$

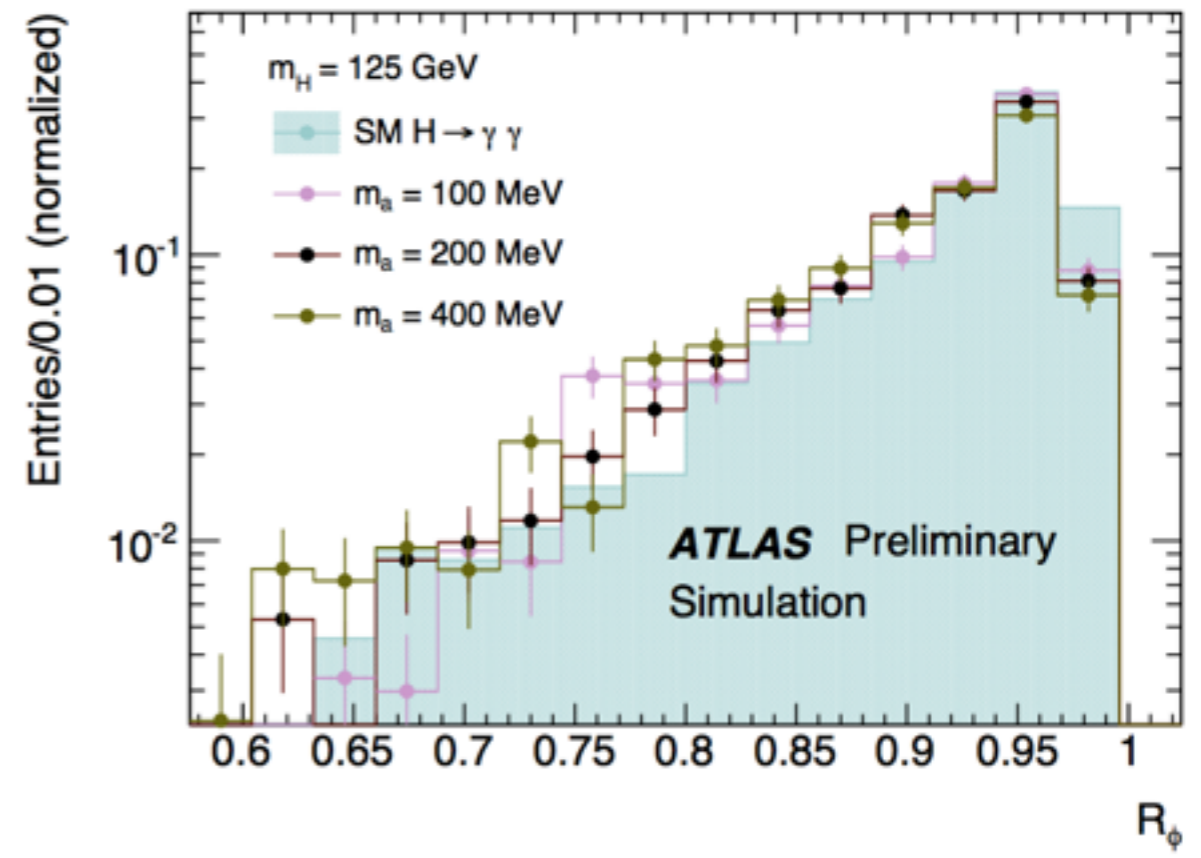

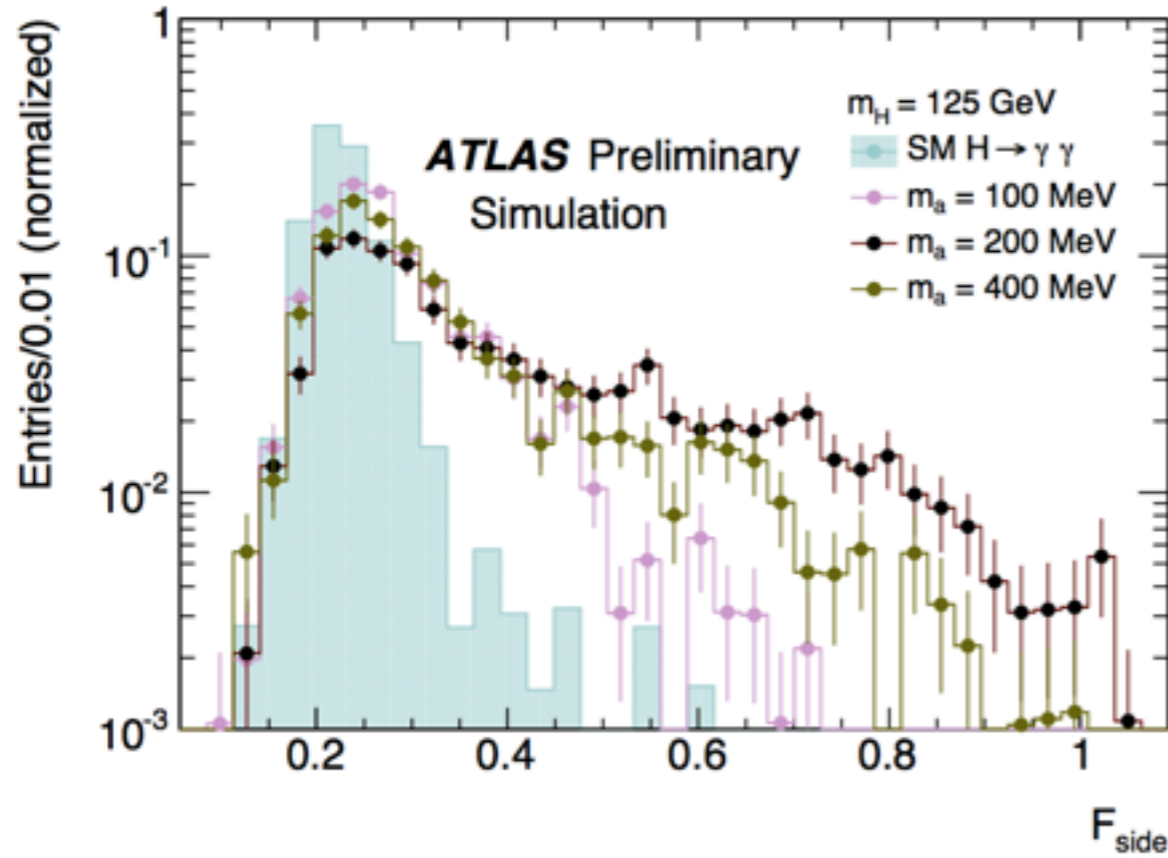

$w_{s3} = w_s$, uses 3 strips in η ;
 w_{stot} is defined similarly, but uses 20 strips.

Cut-based tight is a combination of nine discriminants based on energy in ECal cells in layers 1 and 2 and leakage in the HCal

$R_{\text{had}}, R_\eta, R_\phi, w_{\eta,2}, \Delta E, w_{s,\text{tot}}, f_{\text{side}}, w_{\eta,1}, E_{\text{ratio}}$

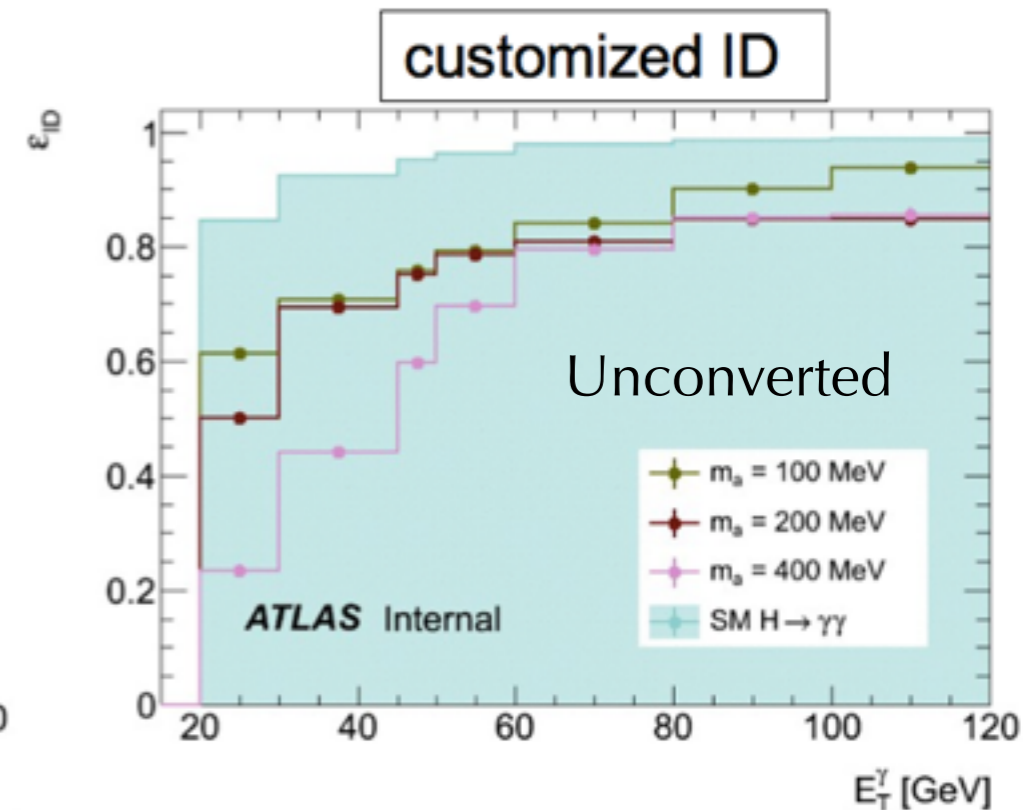

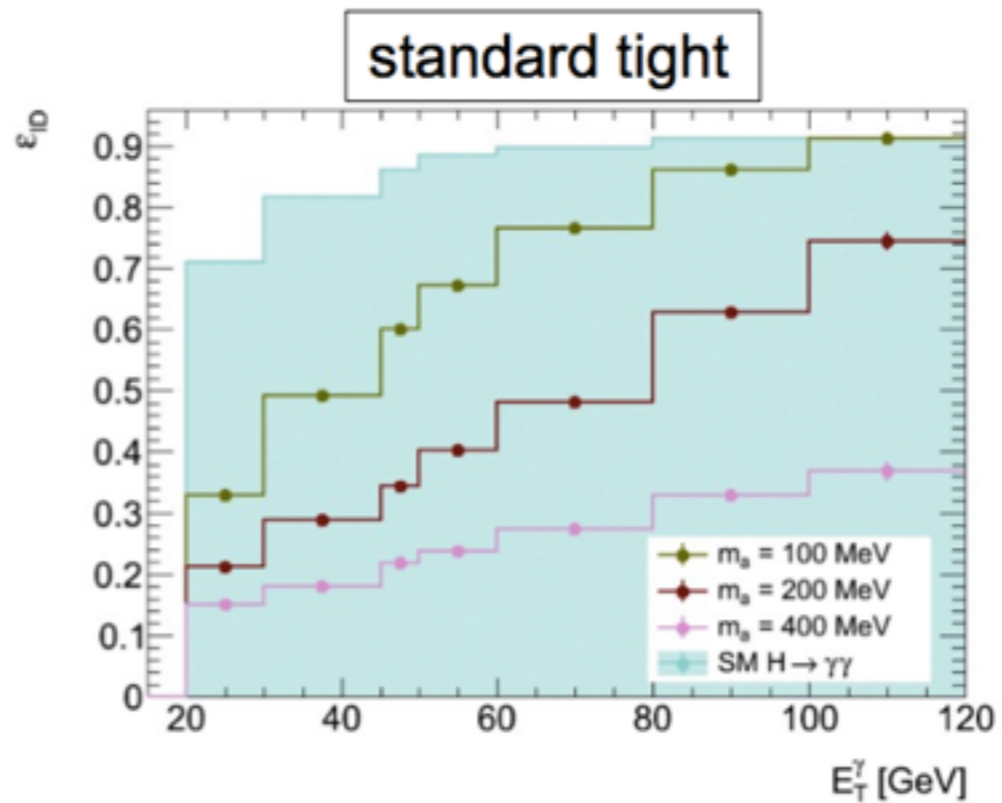

- Separated single photons from two collimated photons with a custom photon ID
- Standard “tight” ID, two kinds of variables: Width and shower structure
- For custom ID, keep only those variables least sensitive to inner structure of the showers

Choosing shower shape variables

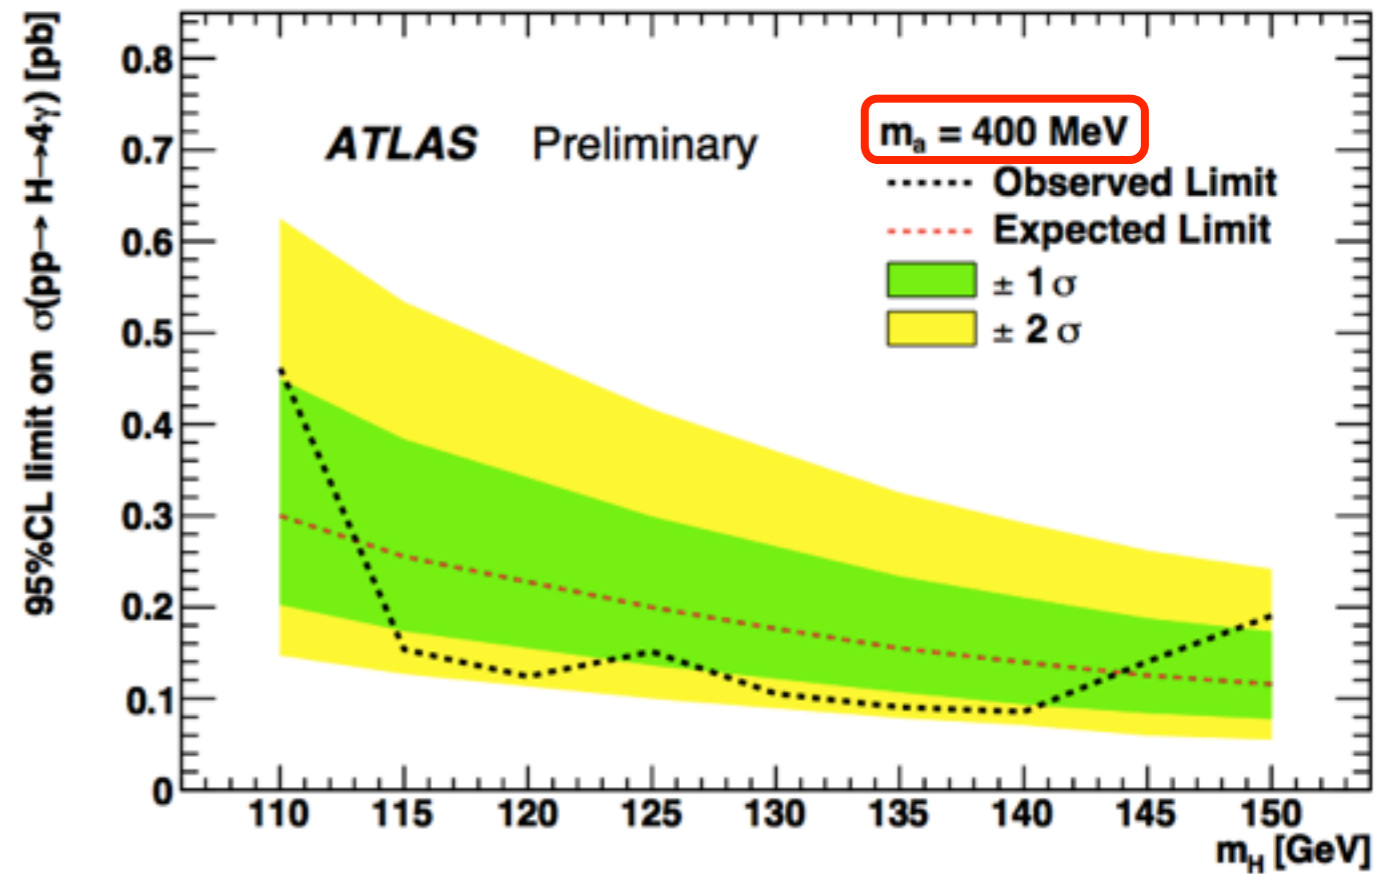

F_{side} : fraction of energy leaked outside the central core of three cells centered around the cell with most energy in the cluster, but still within seven cells

Clearly this will be different for photon-jets and photons

Results and limits

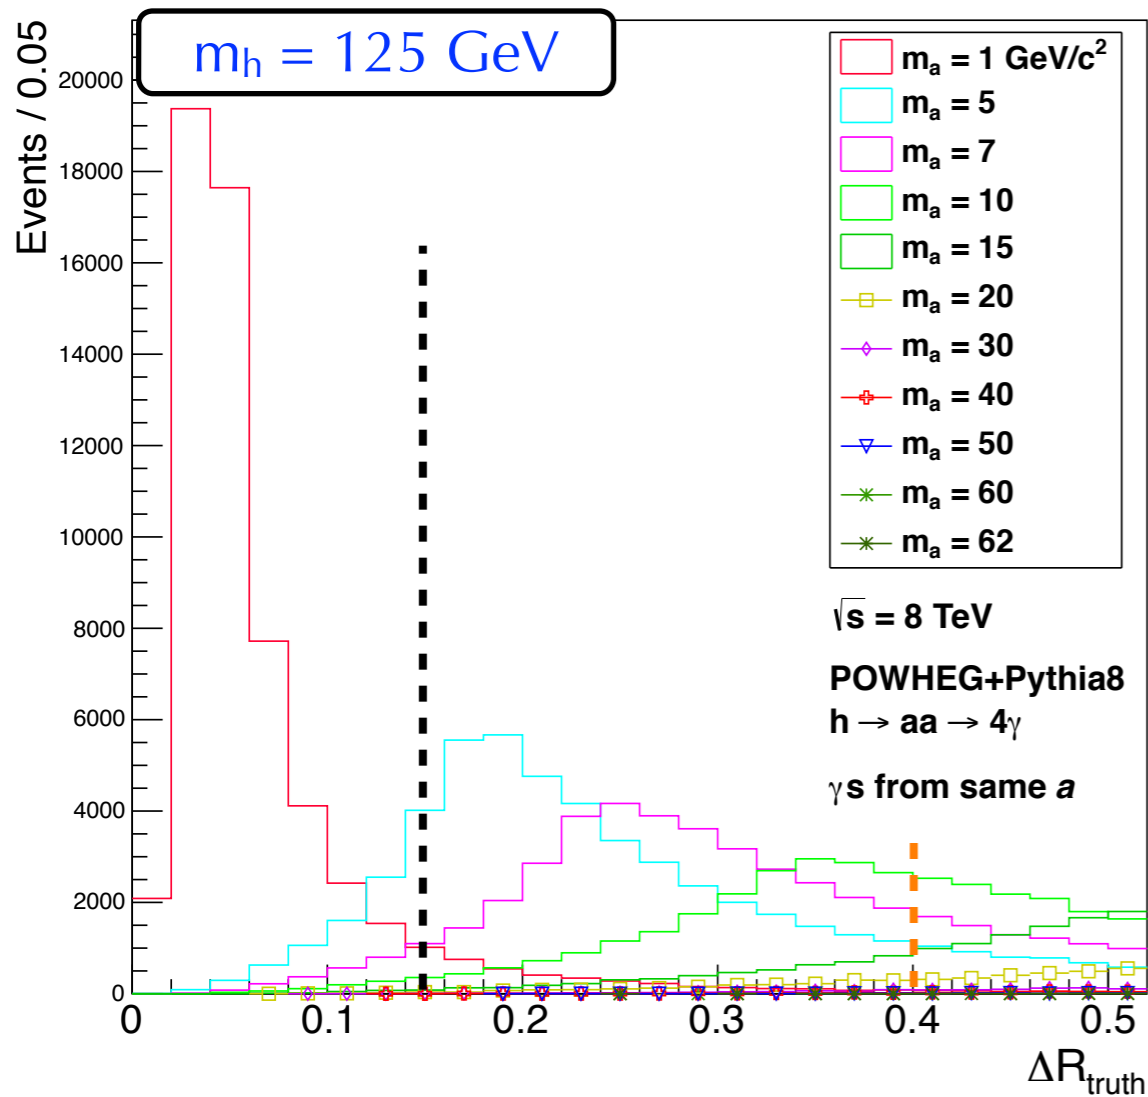

Background model is a fit to the diphoton mass spectrum with the custom ID

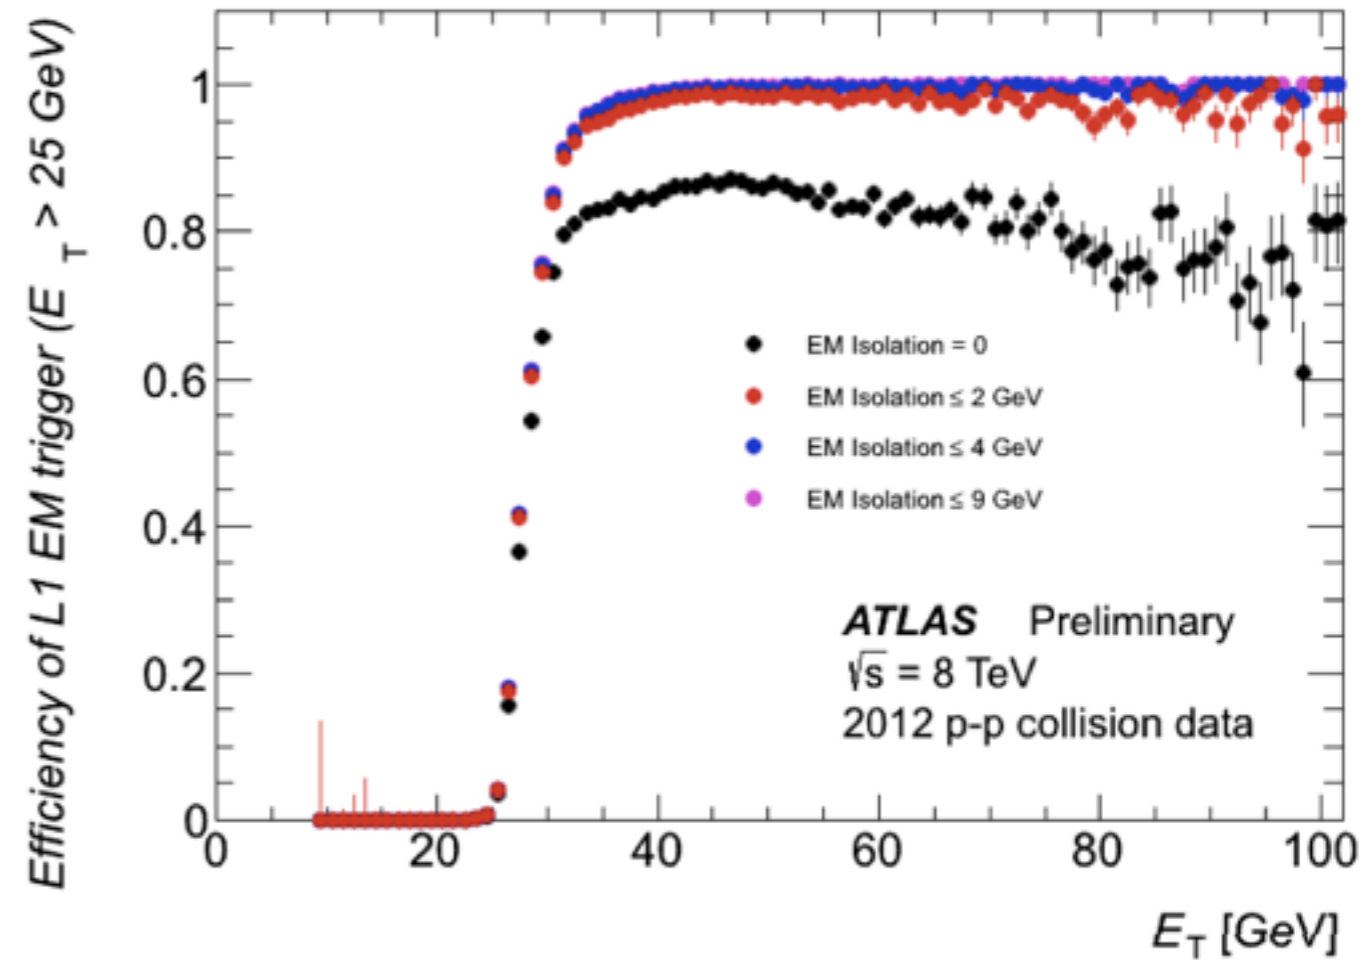

- Signal model: Crystal Ball + Gaussian from fits to Powheg+Pythia signal
- No excess seen and good exclusions made for $100 \text{ MeV} < m_a < 400 \text{ MeV}$
- Limit can be improved, though, either with the full 20.3/fb at 8 TeV or 13 TeV

Level 1 EM triggers use “EM ring” and “hadronic core” isolation

- Immediately limits sensitivity to photon-jets scenarios like $h_{125} \rightarrow aa \rightarrow 4\gamma$

5x7 cluster ==>
 $\langle \Delta R \rangle = 0.15$

Efficiencies of L1 triggers with $E_T > 25 \text{ GeV}$ with optimisation of threshold depending on η

Hadronic leakage and electromagnetic ring isolation requirements as a function of offline electron E_T

Started as a dedicated search for
 $h_{125} \rightarrow aa \rightarrow 4\gamma$ for higher m_a

- Event selection straightforward, low background

Challenges

- Signal efficiency for 4γ low ($h_{125} \Rightarrow$ relatively low photon p_T)
- Background estimate difficult (sub-optimal jet MC statistics)
- Needed data-driven jet background estimate; was unclear if existing methods would work for higher photon candidate multiplicity

Removed requirement on 4th γ

- Signal efficiency much higher for 3γ
- Still sensitive to resonances in 2γ spectrum
- Found we were sensitive to many other signal scenarios

Became a general search for new phenomena in events with at least three photons

Shameless plug

World's best limit on $BR(Z \rightarrow 3\gamma)$

- $2.2(2.0)e-6$ obs(exp)
- **(almost 5 times better than LEP)**
- SM prediction: $5e-10$

Other scenarios

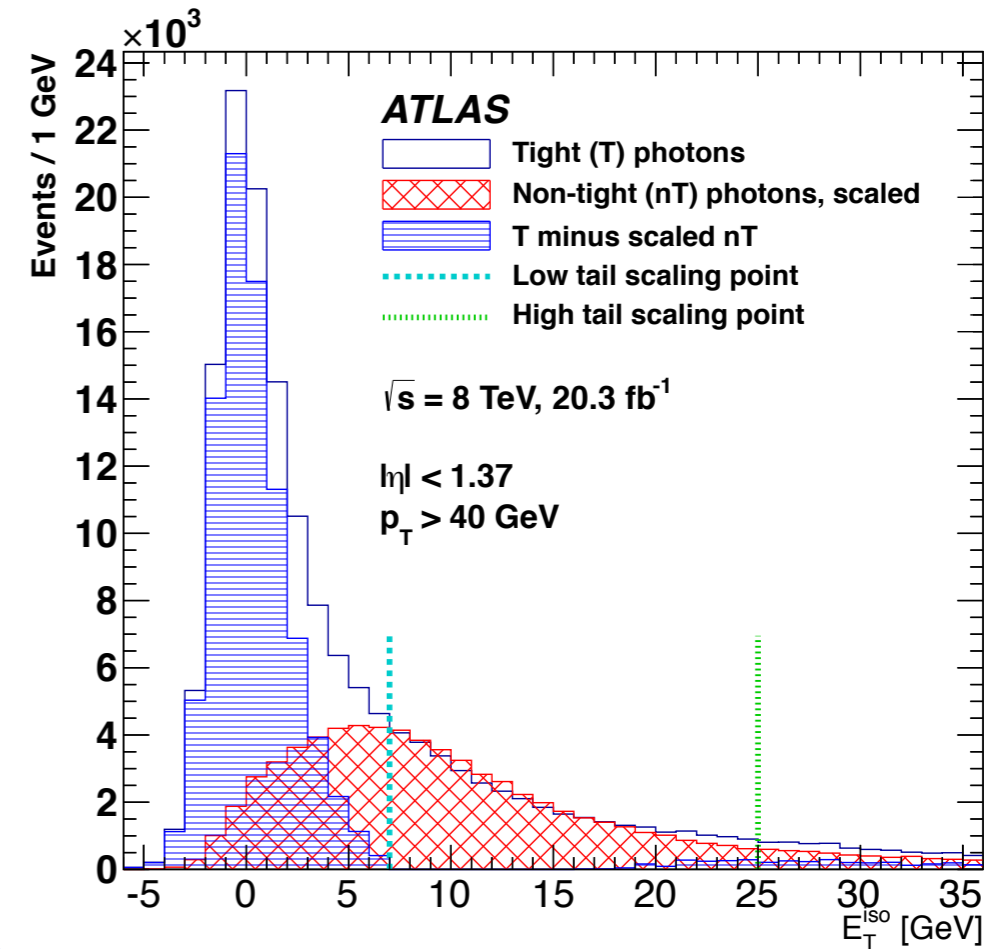

Z' to photons

Rare Z decays

Search and presentation of results

- Event-counting in inclusive signal region, $Z \rightarrow 3\gamma$ signal region, and fiducial kinematic region
- Most general results on fiducial cross section for new phenomena
- Backgrounds: Combination of data-driven (for jets) and MC (all other)
- Jet background estimate using likelihood matrix method, exploiting photon-candidate isolation profiles/efficiencies for “tight” vs. “non-tight” that are enriched in true photons vs. true jets
- Resonance searches in $2/3\gamma$ mass spectra
 - Search for local excesses corresponding to detector mass resolution
 - Background entirely from data, via sideband fit

Each is relevant for $h_{125} \rightarrow aa \rightarrow 4\gamma$

Object and event selection

Three-photon trigger; all photon candidates with $p_T > 15$ GeV

Object pre-selection

- Pseudorapidity:
Good photon candidates satisfy
 $|\eta| < 1.37$ or > 1.52 , $|\eta| < 2.37$
- Photon ID: Loose
- $\Delta R > 0.15$ for all pairings of pre-selected photons

Final event selection (signal region)

- $N_{ph} \geq 3$ photon candidates
- p_T : γ_1 and γ_2 both with $p_T > 22$ GeV,
 γ_3 with $p_T > 17$ GeV
- Photon ID: Tight
- Isolation: Cone: $\Delta R = 0.4$; $E_T^{iso} < 4$ GeV
 - Correction applied to isolation for photons with another high- p_T photon within isolation cone; improves low- $m_{2\gamma}$ signal efficiency significantly

Results and general results

| Process | Inclusive signal region | |
|-------------------------------|-------------------------|-----------|
| 2 γ (sim.) | 330 | ± 50 |
| 3 γ (sim.) | 340 | ± 110 |
| 4 γ (sim.) | 1.3 | ± 0.4 |

| 900 | 100 | 0.680 ± 0.003 | $17 \left(20^{+6}_{-5} \right)$ |

General results for $h_{125} \rightarrow aa \rightarrow 4\gamma \dots$

...but we can do better than this

Searches are performed for resonances with widths corresponding to mass resolution for 2γ cases

- Resonance widths are determined via fits to signal MC
- Since pseudoscalar a (for $m_{2\gamma}$) is generated with a narrow-width approximation, mass resolution corresponds to the general detector resolution

The resonance searches are translated into limits on cross sections for BSM processes; $h \rightarrow aa \rightarrow 4\gamma$ for $m_{2\gamma}$

Three possible choices for 2γ pairings in 3γ signal region events

- p_T -ordered photons
- Calculate widths separately for each pairing: $\{\gamma_1, \gamma_2\}, \{\gamma_1, \gamma_3\}, \{\gamma_2, \gamma_3\}$
- Perform three separate resonance searches in three $m_{2\gamma}$ spectra
- Factor in “ m_{ij} efficiency” when determining limit

Resonance search results for $h_{125} \rightarrow aa \rightarrow 4\gamma$

Multi-photon signatures

Limited sensitivity at medium-low-mass two-photon resonances

Highest limit for $m_a \sim 400 \text{ MeV}$

Lowest limit for $m_a = 10 \text{ GeV}$

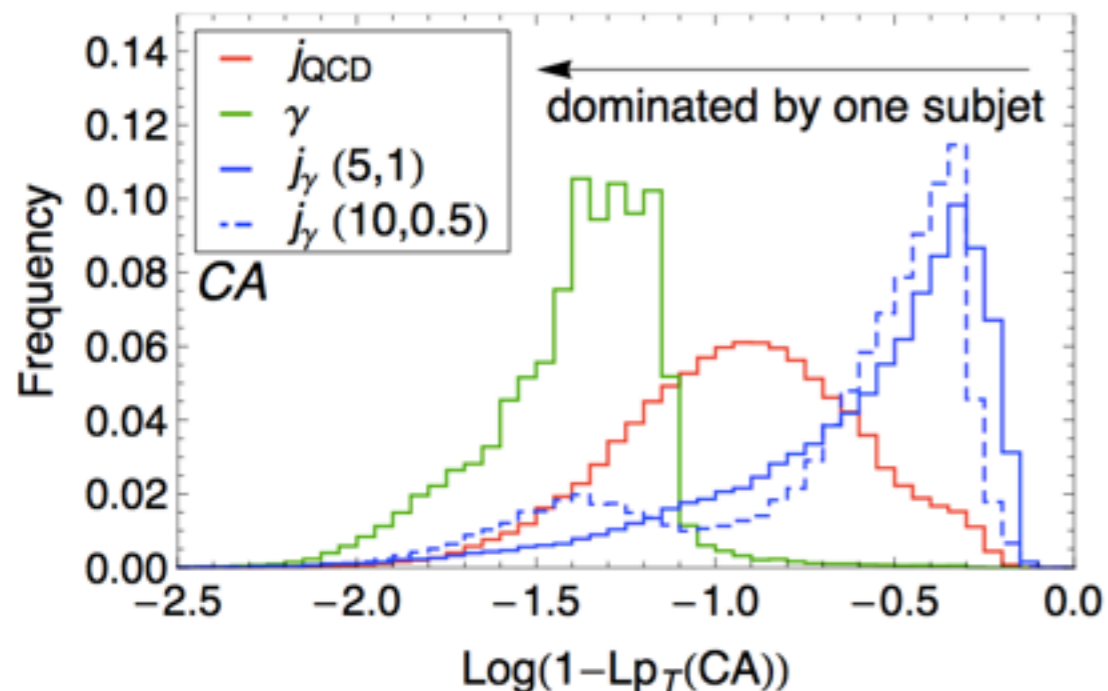

Photon-jets

- J. Scholtz and his collaborators S. Ellis and T. Roy developed multiple methods involving conventional and jet-substructure-inspired ways to ID these objects and separate them from background

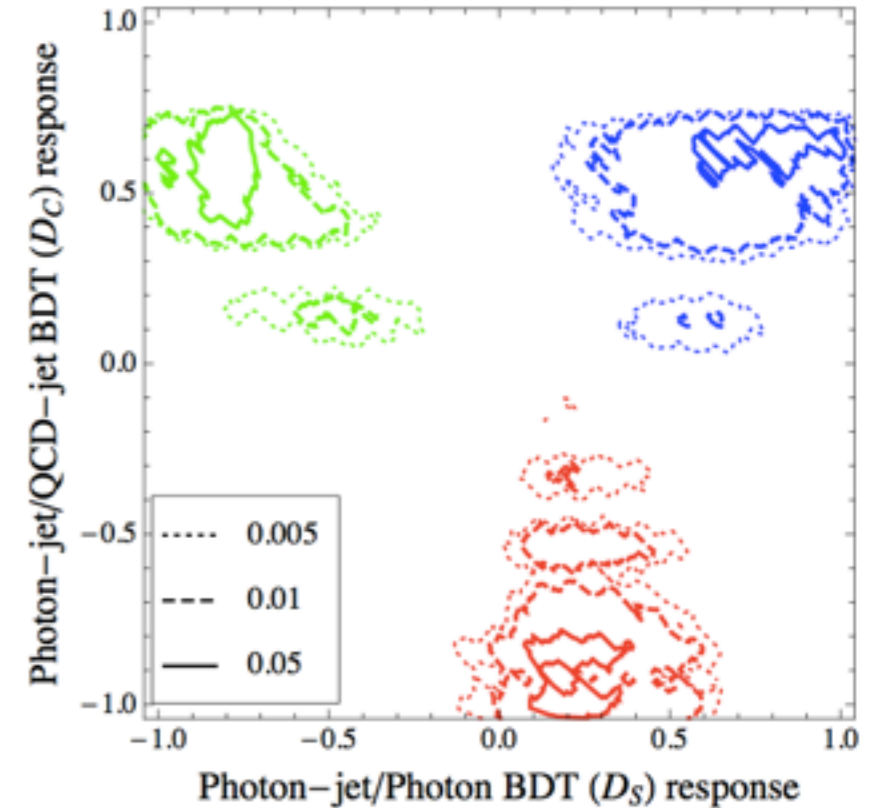

PRD 87, 014015
PRL 110, 122003

$$Lp_T = \frac{\rho_T \text{ of the hardest subjet}}{\rho_T \text{ of the entire jet}}$$

Separating Photons, Photon-Jets and QCD

- ▶ We use two BDTs to extract as much information as possible.
- ▶ Split QCD-jets away with *only Conventional* variables.
- ▶ Split Photons from photon-jets with *just Substructure*.
- ▶ QCD-jets
photons
photon-jets.

J. Scholtz

Photon-Jets

February 9, 2016

29 / 33

- Investigation of these and other methods is ongoing at 13 TeV, involving new triggers, photon-jet ID, etc.
- Higher multiplicity photon-jet possibilities, too

Side benefits of X750 fire drill

- A few more people thought a little more carefully about big-H, boosted-a scenarios

Example:
[arXiv:1602.04692](https://arxiv.org/abs/1602.04692)

- (11) = two real photons
- (22) = two photon-jets
- Discrimination here to use photon conversion rate to distinguish between scenarios with the December 2015 diphoton mass spectrum

Conclusions

Photons are an excellent handle to search for exotic decays of h125

- For $h_{125} \rightarrow aa \rightarrow 4\gamma$ ATLAS has results at 7 TeV for the completely collimated photon-jets case ($100 \text{ MeV} < m_a < 400 \text{ MeV}$) and at 8 TeV for the at-least-three isolated photons case ($10 \text{ GeV} < m_a < 62 \text{ GeV}$)
- Gap between these being filled now with new work involving triggers, new photon-jets ID with substructure, etc.
- Can improve reach for the isolated regime with a dedicated four-photon search with a large Run 2 dataset
- New methods will additionally help cover a wider range of m_h and m_a for more generic extended Higgs sectors (and otherwise)
- Also investigating other explicitly distinct highly-collimated photon-jet scenarios such as $a \rightarrow 3\pi^0$

Future future work

- Di-Higgs production and decays to 4γ (10s of ab^{-1} at FCC?)
