# Forward physics options at the FCC

by Helmut Burkhardt (CERN)

## Future Circular Collider Study, FCC http://fcc.web.cern.ch Indico / Projects / FCC

#### Goal

The Future Circular Collider study has an emphasis on proton-proton and electron-positron (lepton) high-energy frontier machines. It is exploring the potential of hadron and lepton circular colliders, performing an in-depth analysis of infrastructure and operation concepts and considering the technology research and development programs that would be required to build a future circular collider. A conceptual design report will be delivered before the end of 2018, in time for the next update of the European Strategy for Particle Physics.

Studies on the accelerator and <u>machine-detector interface</u> for 2 high luminosity interaction regions are in progress, energy deposition studies well advanced

Here some early considerations on forward physics options, as seen from the machine side -- recalling and slightly extending what I said last meeting on 27/10/16

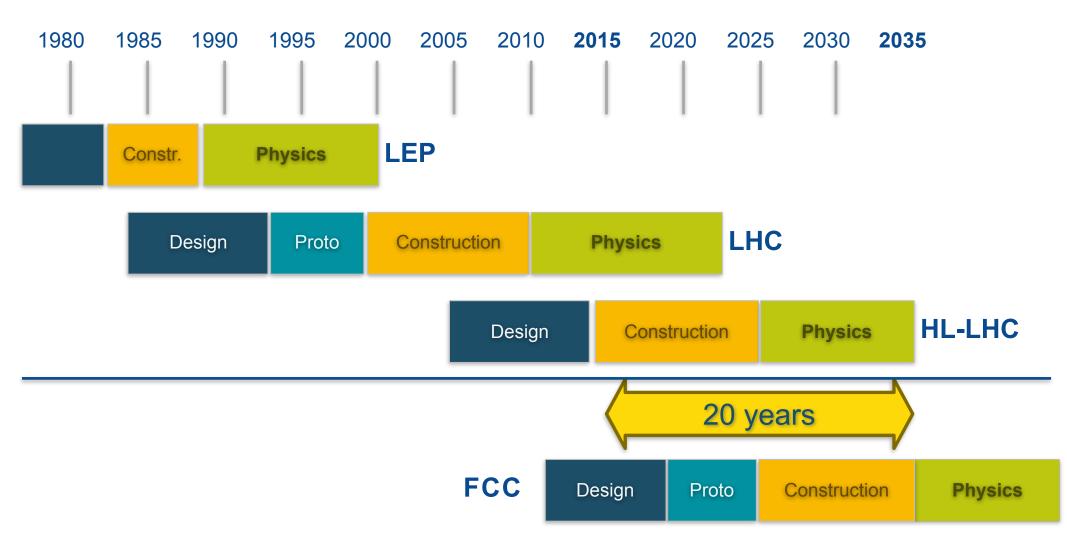

**Acknowledgment :** 

discussion with FCC-hh design team, Daniel Schulte, Xavier Buffat et al.

Time scale

# CDR by end 2018 for next strategy update

**Future Circular Collider Study** Michael Benedikt Academic Training. 2 February 2016

# Hadron Collider FCC-hh

## CERN-ACC-2015-132 of 21/10/2015

Baseline Parameters **100 TeV** c.m.s L = 100 kmInjection energy 3.3 TeV

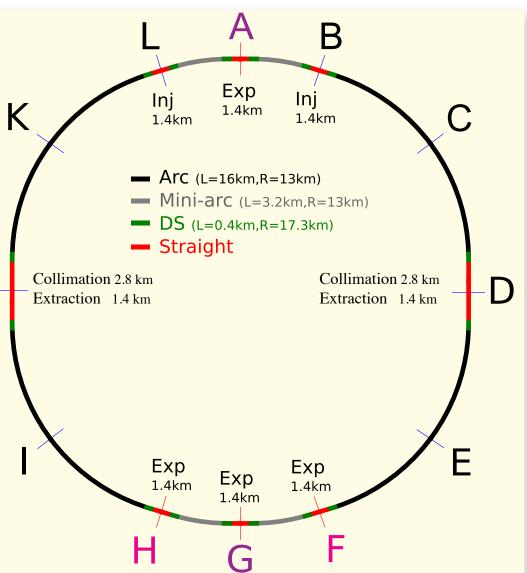

Baseline, 25 ns option :  $L = 5e34 \text{ cm}^{-2}\text{s}^{-1}$  leveled  $\int Ldt = 250 \text{ fb}^{-1}$  per year and IP

#bun = 10600, 1.e11 / protons per bunch  $\epsilon_N = 2.2 \ \mu m$ 

Non negligible SR: 2.4 MW per beam E<sub>crit</sub> 4.3 keV (≈ SuperKEKB)

High luminosity IPs A, G :  $\beta^* = 1.1 \text{ m}$ , x-ing angle  $\pm 45.5 \mu \text{rad}$ 

IPs H, F not yet defined

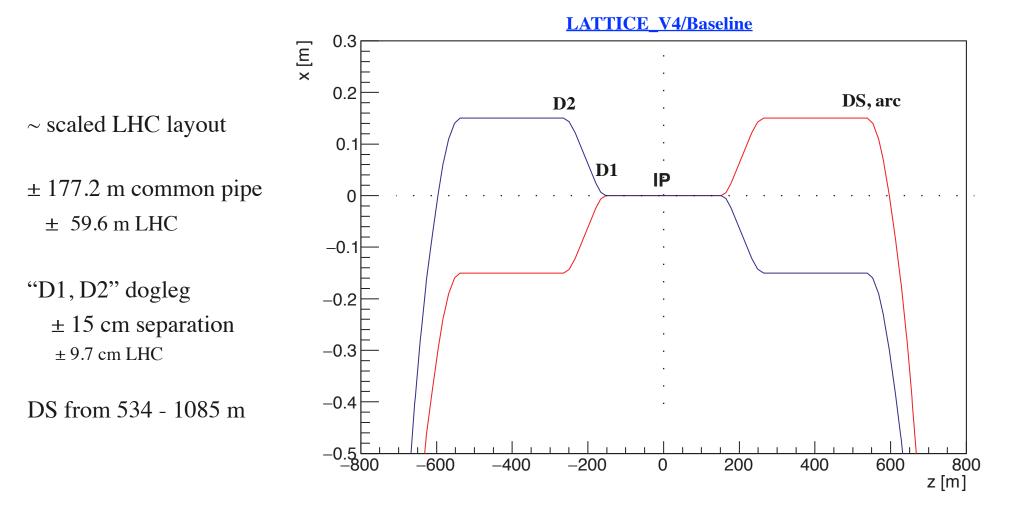

Schematic collider layout. The straight insertions are shown in red and the arcs in black; the anticipated space for the dispersion suppressors is indicated in green.

## FCC, current low β IP layout

**Extra IPs** 

LHC IP2, IP8 - magnet/optics very similar to high-lumi IP1 / IP5 More constraint by injection.

Extra IPs not yet studied in any detail for FCC Potentially very interesting -- support from physics community (you) essential

Could potentially be used for an optimized lower luminosity, higher  $\beta^*$  forward/diffractive IR was also considered for the SSC (SSC-88 9/1986, D.E. Groom et al.)

FCC: extra IP's H, F

- Same 1.4 km length as high luminosity IPs A,G
- not constraint by injection

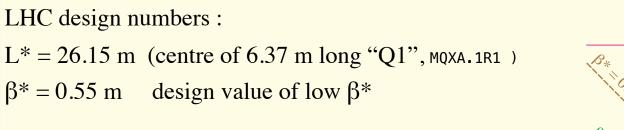

More dedicated lower luminosity IR :

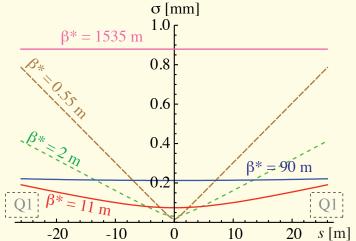

- Integration of detectors in IR layout : early planning may allow for integration of forward detectors in *machine sections* and better optimization for higher dispersion in the dogleg : Forward physics instrumentation, Rainer Schicker, FCC hadron detector meeting 27/07/2015 or in the dispersion suppressor (FP420 equivalent for FCC)
- Lower luminosity  $\rightarrow$  less shielding and radiation does not necessarily exclude lower  $\beta^*$ . Possible synergies with heavy ion mode

- $\beta^* << L^*$  low beta small beams at IP. 90° phase advance L/R and strong focusing triplet high angular divergence
- $\beta^* >> L^*$  high beta large parallel beams, low angular divergence ~ no phase advance and focusing

FCC-numbers, fcc\_ring\_v4\_baseline, roughly 2× the LHC

- $L^* = 46 \text{ m}$  (centre of 20 m long "Q1", MQXC.1R )
- $\beta^* = 1 \text{ m}$  design value of low  $\beta^*$

Scaling, from LHC to FCC

FCC: E, 
$$\gamma$$
 increases by factor 100 / 14 = 7 in  $\sqrt{\gamma}$  by 2.7 scaling  
Beam size at IP  $\sigma^* = \sqrt{\beta^* \epsilon} = \sqrt{\beta^* \epsilon_N / \gamma}$   
Angular beam divergence  $\sigma' = \sqrt{\varepsilon / \beta^*} = \sqrt{\varepsilon_N / (\gamma \beta^*)}$   
Luminosity, round beams  $\mathcal{L} = \frac{N^2 f}{4\pi \sigma^2} = \frac{N^2 f \gamma}{4\pi \beta^* \varepsilon_N}$   $\gamma$   
Minimum  $t$  with RP at  $n_\sigma$   $-t_{\min} = \frac{2 p n_\sigma^2 \epsilon_N m_p}{\beta^*}$   $\gamma$ 

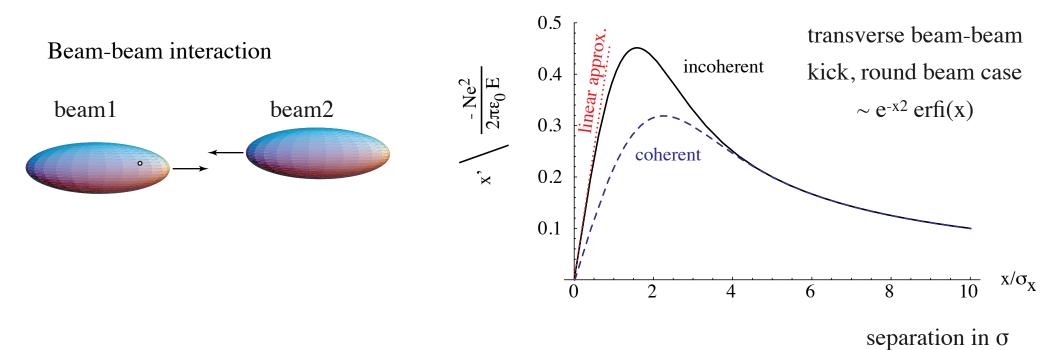

Normalized emittance  $\gamma \epsilon = \epsilon_N = 2.2 \ \mu m$  constant in (lower energy) proton machines, determined by injectors, similar for all proton machines. Beams shrink when accelerated. Difficulty to reach a certain minimum *t* (i.e. Coulomb IR) increases ~ linear at constant  $\epsilon_N$  with  $\gamma$  from  $\beta \sim 2 \ km$  at LHC (yet to be reached) to ~ 14 km at FCC ?

In FCC, **damping** from SR+RF significant, opens up possibility to get significantly lower emittance --- **potentially very useful for dedicated runs** 

# **Reminder :** Low luminosity ≠ No interference

## Quantified by tune shift parameter $\xi$

head-on, round beams

$$\xi = \frac{r_c N}{4\pi \,\epsilon_N}$$

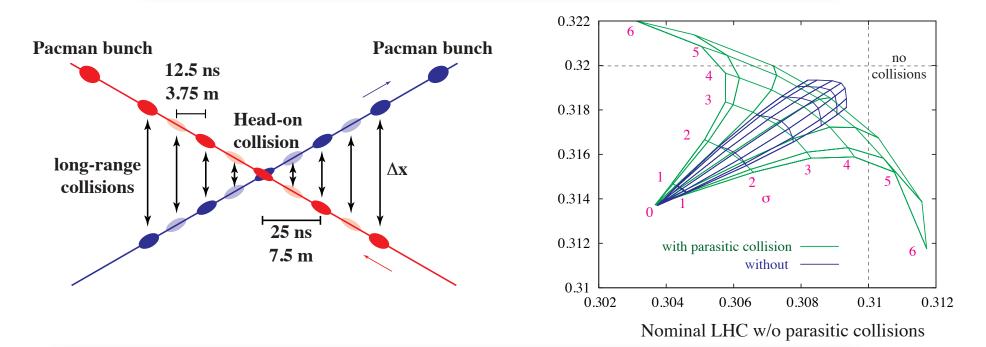

depends only on N /  $\epsilon_N$ not on energy and **not on \beta^\***  Head on : same beam-beam from low lumi high- $\beta$  as high lumi IPs

To reduce b.b. would require to run separated by several  $\sigma$ 

# Principle of separation by crossing angle at higher $\beta^*$

Low  $\beta^*$  (< L\*)

beam size and separation increase  $\propto \Delta s$ ,  $\Rightarrow$  separation in units of  $\sigma$  about constant around IP all parasitic crossings adding up with similar contribution

### Instead high $\beta^*$ :

beam size ~ constant =  $\sigma^*$ , separation in  $\sigma$  increases as  $\Phi\Delta s$ where  $\Phi$  is the crossing angle, dominated by 1st parasitic crossing 100 ns bunch spacing 4× more separated than 25 ns, used for 90m LHC and negligible contribution from next 200, 400 ns ...

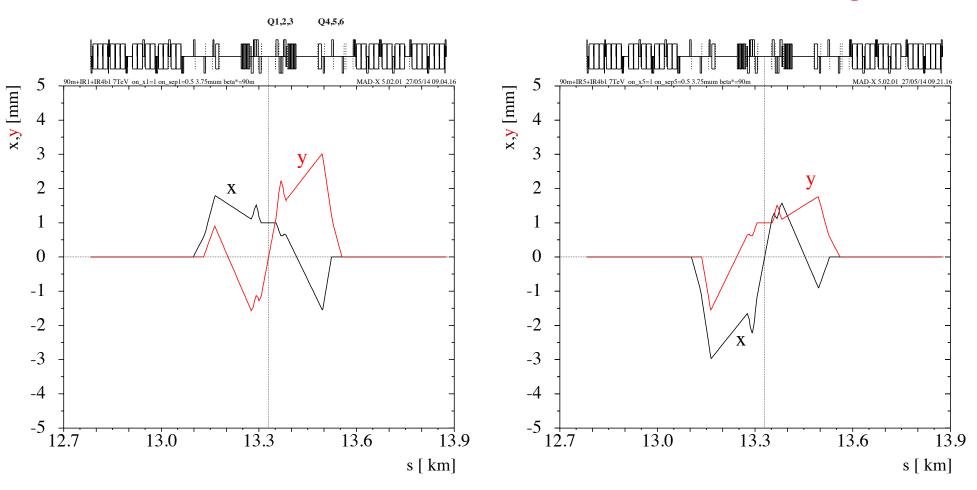

### Vertical crossing

IR5, CMS-TOTEM Horizontal crossing

#### Shown for ±1 mm separation

± 50 μrad (half) crossing angle --- limited by corrector strength (+ injector RF) to 100 ns spacing or 4x reduced #bunches

With sufficient corrector strength and aperture : 25 ns spacing in dedicated FCC IR

11

**Parasitic** running in standard physics next to high luminosity IP, with tens of kilowatts of collision debris will be difficult. Important to plan this before.

Consider 3 scenarios - of which 1.+2. best at dedicated lower luminosity IP

1. Dedicated very high  $\beta^*$  operation for cross section measurements Few bunches, no crossing angle. Few dedicated runs.

Roman pots very close (few sigma).

Minimize beam-beam (no collisions in other IPs, moderated bunch intensities) :

**Profit from SR/RF radiation damping :**  $\epsilon_N = 2.2 \ \mu m \times exp(-t/\tau)$ 

where  $\tau = 1$  h. After ~ 4 hours at **reduced equilibrium emittance**, maybe as low as ~ 0.05  $\mu$ m

 $\beta^* \sim \text{few km could be sufficient, very high } \beta^* > 10 \text{ km may not be needed}$ 

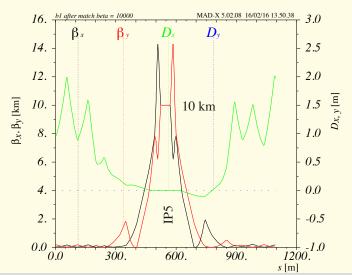

at reduced bunch intensities, more bunches compatible with no crossing angle to get sufficient luminosity to be checked and optimized : damping partition, beam-beam, bunch schemes, IBS

On the other hand there should be

## no principle problem to go to very high $\beta^\ast$

like tenths of km if this is taken into account in the IR design Key ingredients for very high  $\beta^*$ :

- flexible quadrupole powering (bipolar) and large aperture
- sufficient # (  $\geq 6$  ) of independently powered quads IP to RPs
- well separated IR, DS sections
- getting there de-squeeze from  $\beta^* > L^*$

## 2. Moderately high $\beta^* \sim 100$ m operation for forward / diffractive physics

(and minimum bias, proton vs / ion calibration ...) with kind of "ALICE+TOTEM" IR and detectors Design IP such that enough corrector strength and aperture available for sufficient crossing angle ( $\geq 10 \sigma$ ) and parallel separation to operate with full number of bunches with 25 ns spacing Aim : **compatible with standard physics** --- no need for limited special runs Roman pots at ~ 10 sigma ? (after some h in physics )

3. Very forward detectors in very high luminosity insertions A/G "FP420" tagging of protons ( $\xi$  in the range 0.01 - 0.10?) at full luminosity using detectors in the dispersion suppressor needs early planning --- space and integration with magnet / cryo / collimation design

For discussion : contribute to FCC-hh CDR ?

- physics motivation
- requirements in terms of target machine parameters

For each of the running scenarios considered, define the requirements :

- phase advance between IP and RPs
- plane (x, y), w/o crossing angle
- local dispersion between IP and RPs (" $\xi$ " acceptance, D /  $\sqrt{\beta}$ )
- detector acceptance ( $\eta$  ranges)
- closest approach of RPs to beam axis  $n_{\sigma}$  and real space (mm, w/o dead space)
- if required limits on transfer matrix magnification  $v = r_{1,1}$  eff. length  $L = r_{1,2}$
- ∫ L dt
- Pile-up

1st step to get something is to ask for it

On a brain-storming level

--- there appears to be very good potential for forward / diffractive physics at FCC

2 extra IRs not yet studied / assigned

**Could profit a lot from :** 

- More dedicated interaction region
- More space and flexibility
- Reduced emittance (significant SR/RF damping)
- Potentially compatible with standard operation
- Detectors in higher dispersion sections (dogleg, DS)
