

## Thin curved bulk Micromegas for CLAS12

Stéphan Aune, Jacques Ball, Piotr Konczykowski, Caroline Lahonde,  
Olivier Meunier, Franck Sabatié, Sébastien Procureur  
CEA-Saclay (SPhN & Sedi)

# Outline

## Introduction: Jefferson Lab and CLAS @ 12 GeV

## Detector simulations

- *Optimization & characterization of the detector with Garfield*
- *Studies of the background rate with Geant4*
- *Tracking performance*

## Tests of prototypes

- *Measurement of Lorentz angles up to 4.2 T field*
- *Results from cosmic rays*

## Conclusion and planning of the project

CEBAF  
Large  
Angle  
Spectrometer

# Jefferson Lab today... and tomorrow

## Continuous electron beam

- Energy from 0.8 to 6 GeV
- Duty factor 100%
- Beam polar ~85%
- Delivers 3 halls simultaneously

**CD-3 passed last year**  
**Construction just started**  
**Beginning of operation: 2015**

# The 12 GeV project & CLAS12

Large physics program at 12 GeV:

*Search for exotic mesons & origins of confinement (new Hall D)*

*Physics of nuclei (partonic structure, interactions from QCD principles)*

*Studies of the nucleon structure (in particular mapping of GPDs)*

...

Hall B needs to be upgraded → CLAS12

$$L=10^{35} \text{ cm}^{-2}\text{s}^{-1}$$

Original design for Central Tracker:

- Barrel: 4x2 polygons of Silicons (strips at  $\pm 3^\circ$ )
- Forward: 3x2 disks of Silicons (strips at  $\pm 12^\circ$ )

# Micromegas for CLAS12

Proposition from Saclay to replace a large part of Si with MM bulk detectors...

**3 cylindrical double layers (Barrel)**

(X-Y strips at 0 and 90°)

**3 flat double layers (Forward)**

(U-V strips at ±30°)

4m<sup>2</sup> and ~30k channels in total

$X_0 = 0.24\%$  / layer

... but highly unfavourable conditions:

- **Barrel: large Lorentz angle (5 T transverse field)**

$$\tan\theta \approx v \times B / E$$

⇒ {  
Decrease the drift distance  
Increase the electric field  
Use slow gas

- **Forward: almost no transverse diffusion (B // E)**

⇒ Use gas with high diffusion

⇒ **Garfield simulations to find the best working point (if any)**

# MM optimization (Barrel)

→ Studies made with Ne (large  $v$ ), Xe (heavy & expensive), Ar mixtures ⇒ Ar

Central - Ar -  $V_d = 1700V$  -  $V_{mesh} = 450V$  - pitch = 600 $\mu m$  -  $\alpha = 0^\circ$  - gaps = (2mm; 100 $\mu m$ ) -  $\pi$  @ 1 GeV & 90°

Space resolution

Shift of reconstructed position

Chose Ar+10% $C_4H_{10}$

Gain

Number of primary ionisations

+ Similar studies for the Forward part → Ne,  $CF_4$

# MM optimization (Barrel)

→ Studies of the resolution with the drift high voltage

Argon gas -  $V_{\text{mesh}} = 450\text{V}$  - pitch =  $600\ \mu\text{m}$  - gaps =  $(2.0\text{mm}; 100\ \mu\text{m})$  -  $\pi$  @  $1\ \text{GeV}$  &  $90^\circ$

Space resolution

Shift of reconstructed position

With these conditions,  
pre-amplifications starts  
at  $HV_d \approx 2000\ \text{V}$

$HV_d = 1700\ \text{V}$  for safety

Gain

Number of primary ionisations

Again, separate simulations  
for the Forward

# Geant4 simulations

- The main goal is to determine the background rate seen by the MM at the CLAS12 luminosity
- **Barrel: 2 double layers of Si + 3 double layers of cylindrical MM**
  - **Forward: 3 double layers of flat MM**

# Geant4 simulations

→ Using 62,500 beam electrons ( $\Leftrightarrow$ 132 ns time window, very conservative):

## Strip rates in MHz in the Barrel

Si	Layer 1	Layer 2	Layer 3	Layer 4
e-/e+	3.9	3.7	4.3	4.3
photon	30.5	22.0	25.7	20.0
hadron	1.6	1.3	1.7	1.5
total	36.2	27.0	31.9	26.0

MM	Layer 1	Layer 2	Layer 3	Layer 4	Layer 5	Layer 6
e-/e+	1.27	2.73	1.14	2.92	1.70	3.68
photon	0.08	0.03	0.07	0.06	0.09	0.08
hadron	0.96	0.95	1.13	1.11	0.91	0.84
total	2.40	3.80	2.40	4.15	2.77	4.66

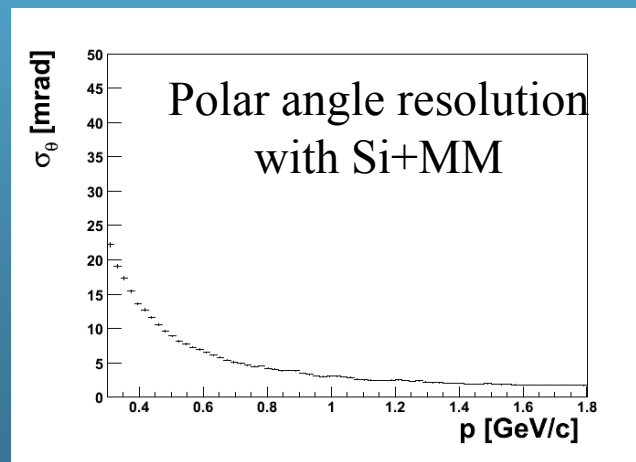

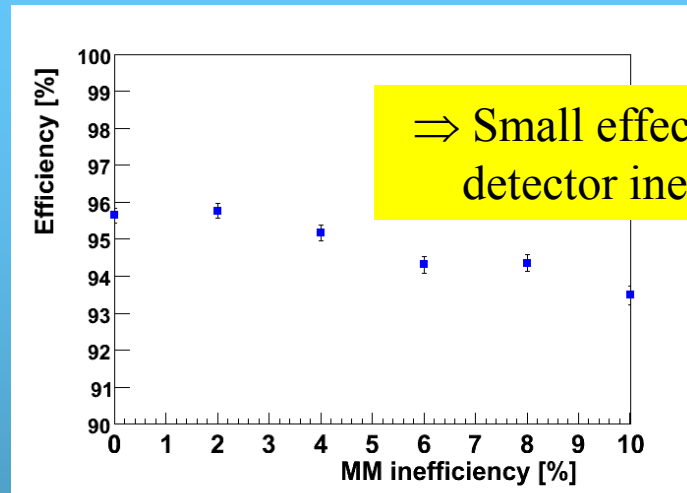

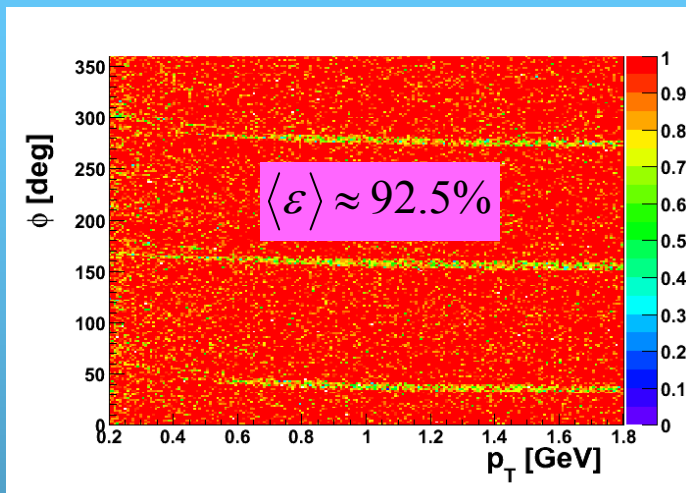

## Strip rates in MHz in the Forward (Si in parenthesis)

	Layer 1	Layer 2	Layer 3	Layer 4	Layer 5	Layer 6
e-/e+	7.6 (7.5)	4.7 (6.4)	4.7 (6.6)	4.0 (7.3)	4.0 (7.2)	3.6 (7.5)
photon	2.0 (13.9)	0.2 (11.3)	0.2 (9.5)	0.1 (8.3)	0.1 (7.1)	0.1 (5.7)
hadron	2.2 (1.6)	2.1 (1.5)	2.0 (1.4)	2.0 (1.4)	1.9 (1.4)	1.8 (1.3)
total	12.0 (23.1)	7.2 (19.3)	7.0 (17.7)	6.2 (17.1)	6.1 (15.8)	5.5 (14.6)

- Significantly smaller rates in MM than in Si, essentially due to photon rate
- *A fortiori* no problem for tracking (already proven for Silicon design)

# Tracking performance (Barrel)

→ performance estimated with Kalman Filter algorithm developed for CLAS12

$\Rightarrow$  Much better  $\theta$  resolution, without any degradation on other variables

# Measurement of Lorentz angle in high B field

# Measurement principle

# Prototype characteristics

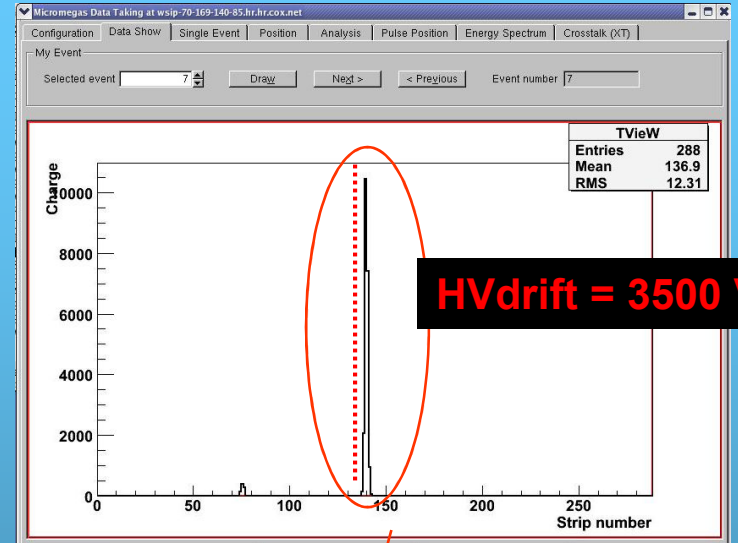

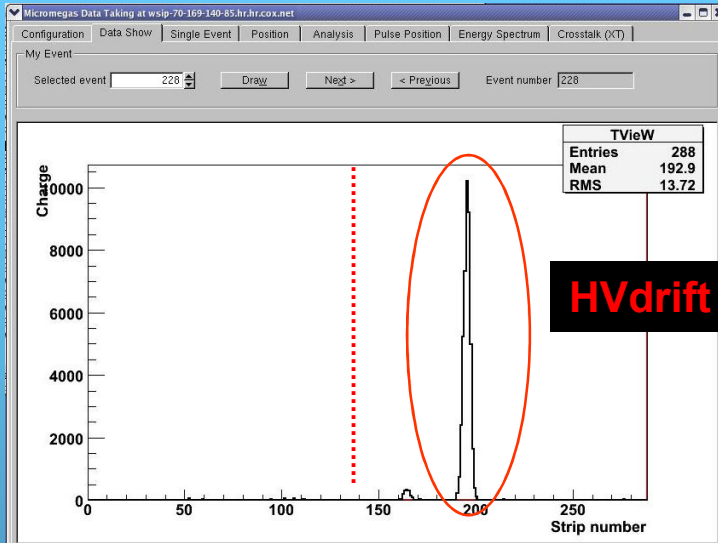

- Drift : Al-mylar
- Drift gap : 3.85mm
- 4\*72 strips
- Pitch : 0.4mm
- Data acquisition : T2K electronics (FEC+FEM) + DAQ
- 90% Ar + 10%  $iC_4H_{10}$

# Signal at 4.2 T

# Results on Lorentz angle

⇒ Good agreement with the simulation ( and 1st measurement at such high B fields)

The image shows an astronaut in a space suit floating in the void of space. The Earth's blue and white horizon is visible in the background. Overlaid on the scene are several colorful, branching particle tracks, representing cosmic rays or secondary particles, extending from the astronaut towards the Earth. The tracks are composed of many small, multi-colored dots (red, green, blue, yellow) connected by thin lines, creating a complex, tree-like structure.

# Tests with cosmic rays

# Experimental setup (Saclay)

# Saclay cosmic ray bench

Flex cables

Reference detector

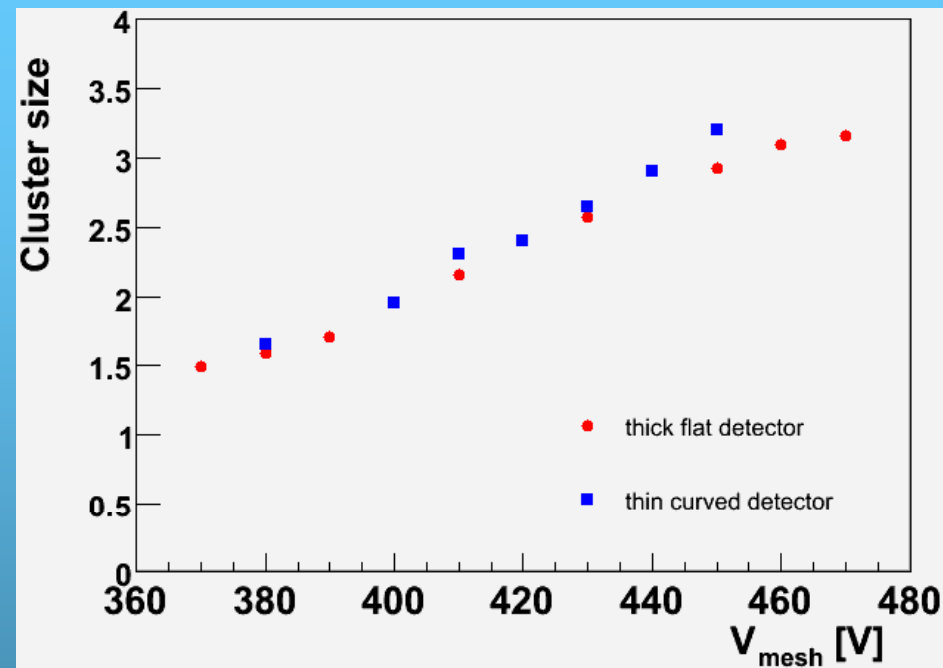

Scintillator Paddle

Lead

Micrometric alignment

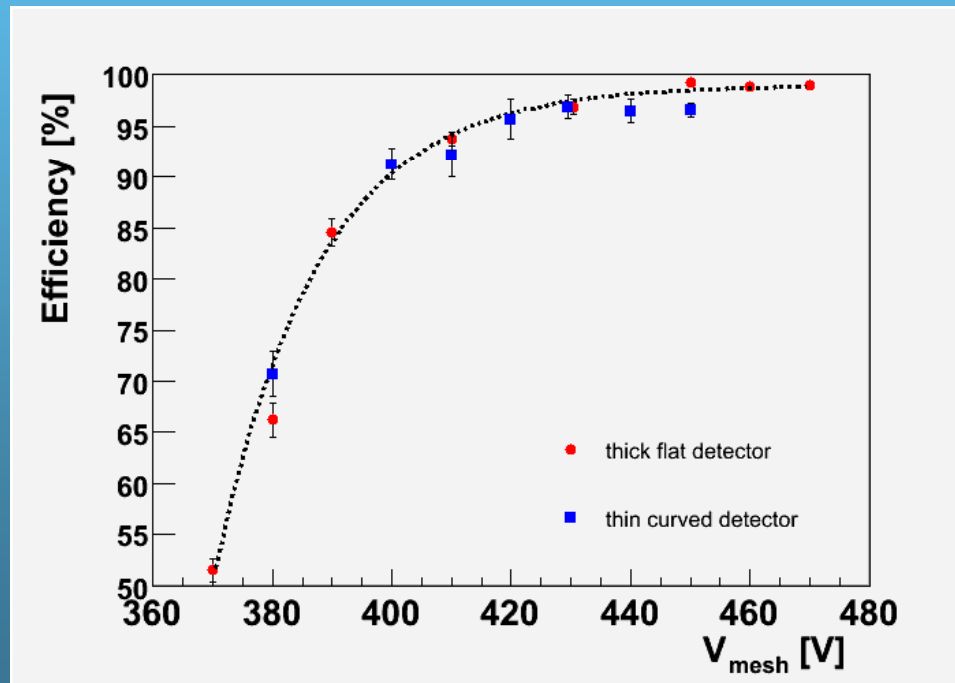

Curved detector  
(demonstrator)

# Flat vs curved Micromegas - 1

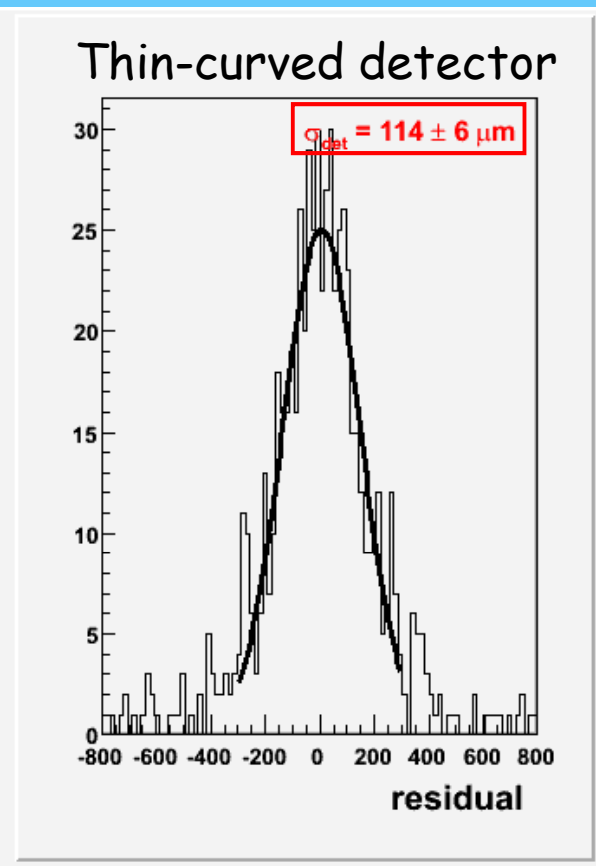

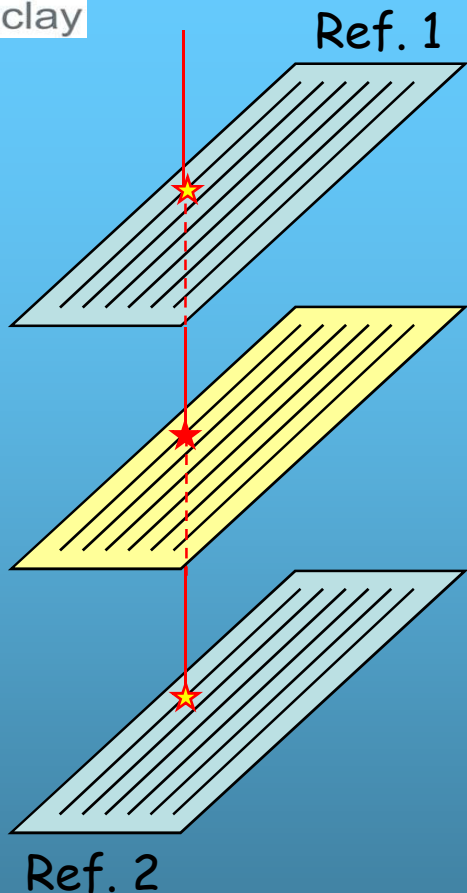

Very similar multiplicity ( a little larger because of track angles)

Similar plateau with curved detector, though a little shorter

# Flat vs curved Micromegas - 2

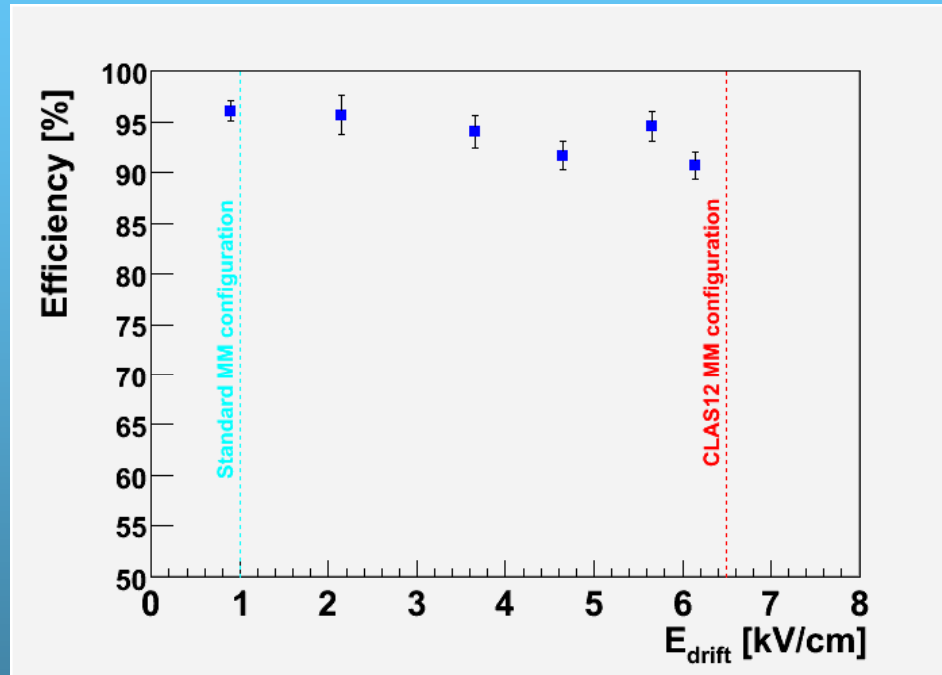

(Probably some misalignments wrt reference detectors... will do better soon with X-Y detectors)

**⇒ Almost no performance differences between flat and curved detectors**

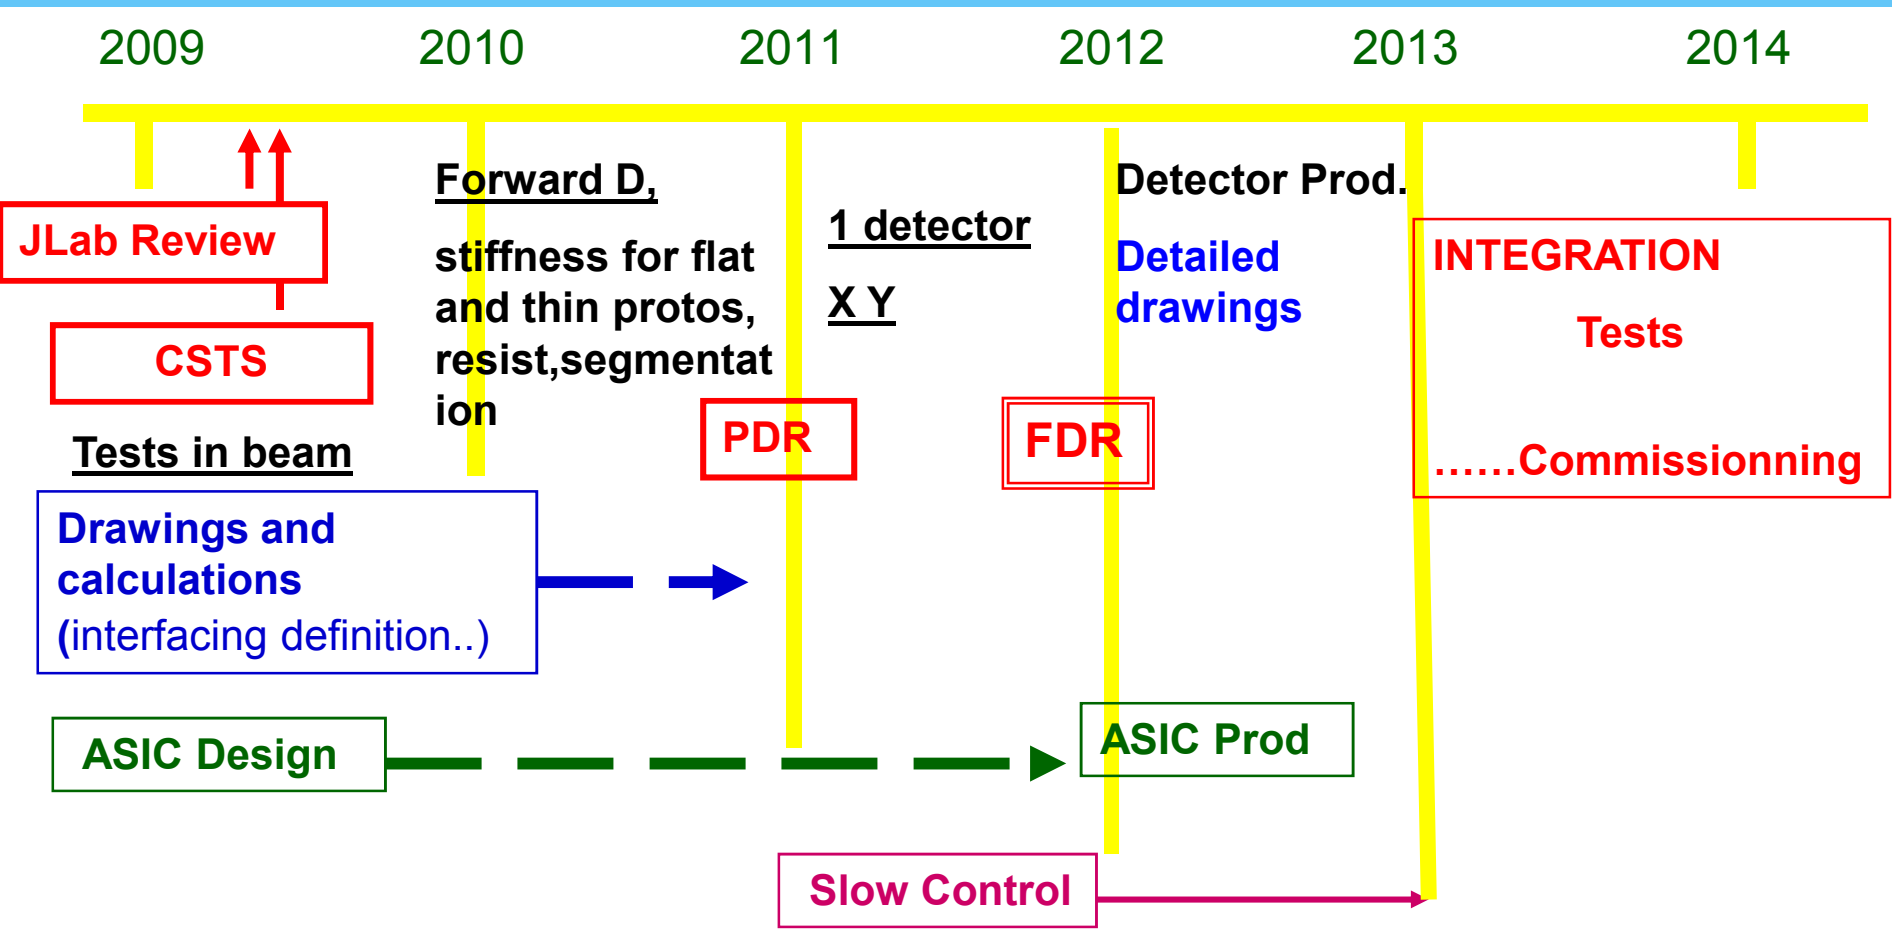

# Transparency and efficiency

Effect of the drift field increase on the transparency and efficiency

**⇒ Transparency is only around 40%, but only a few % effect on the efficiency**

# Schedule

# Conclusion

- Report on the “Review of Micromegas Tracking Detectors for CLAS12” held May 7, 2009 @ JLab

*... We find that the simulated performance for resolution, solid angle coverage and efficiency will meet or exceed CLAS12 requirements*

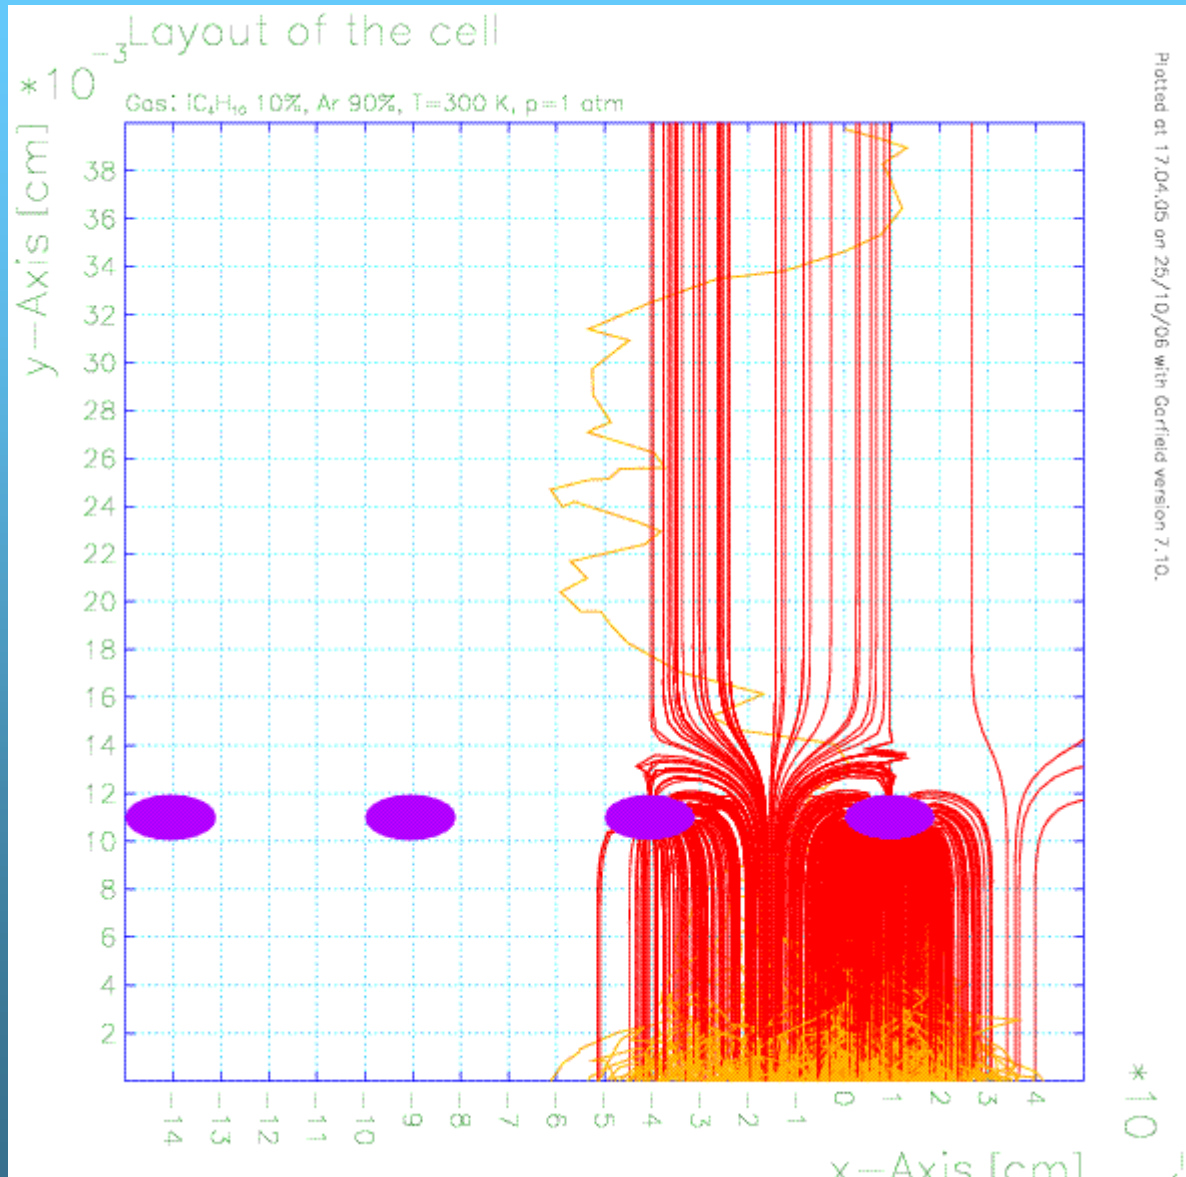

*We see no major obstacles to construction of a successful central tracking system based on the presented conceptual design.*

**Backup**

# Ion transparency-1

$HV_d = 720 \text{ V}$   
 $HV_m = 450 \text{ V}$

# Ion transparency-2

$HV_d = 2000\text{ V}$   
 $HV_m = 450\text{ V}$

# Ion transparency-3

$HV_d = 2000 \text{ V}$   
 $HV_m = 450 \text{ V}$   
 $B = 5 \text{ T}$

# Energy resolution vs radius

# Increase electric field

$$\tan \theta_L = \frac{v(E, B) \times B}{E}$$

# Use slow gas

$$\tan \theta_L = \frac{v(E, B) \times B}{E}$$

Neon mixtures

Argon mixtures

# Flex cable noise studies

Pedestal RMS vs flex PCB length
