OSiRIS
Distributed Ceph and Software Defined Networking for Multi-Institutional Research

Michigan Institute for Computational Discovery and Engineering
October 10, 2016

- Project and participants overview
- Structural overview and site details
- Orchestration, monitoring and visualization
- Networking, NMAL, SDN
- Latency and Ceph - our experiments
- AAA infrastructure
- First science domains: ATLAS and Physical Ocean Modeling
OSiRIS (Open Storage Research InfraStructure) is one of 4 NSF CC*DNI DIBBs projects funded in 2015. OSiRIS is prototyping and evaluating a software-defined storage infrastructure, initially for our primary Michigan research universities, designed to support many science domains.

**Our goal** is to provide transparent, high-performance access to the same storage infrastructure from well-connected locations on any of our campuses.

By providing a single data infrastructure that supports computational access “in-place” we can meet many of the data-intensive and collaboration challenges faced by our research communities and enable them to easily undertake research collaborations beyond the border of their own universities.
Scientists get customized, optimized data interfaces for their multi-institutional data needs

Network topology and perfSONAR-based monitoring components ensure the distributed system can optimize its use of the network for performance and resiliency

Ceph provides seamless rebalancing and expansion of the storage

A single, scalable infrastructure is much easier to build and maintain

Allows universities to reduce cost via economies-of-scale while better meeting the research needs of their campus

Eliminates isolated science data silos on campus:

- Data sharing, archiving, security and life-cycle management are feasible to implement and maintain with a single distributed service.
- Configuration for each research domain can be optimized for performance and resiliency.
OSiRIS is composed of scientists, computer engineers and technicians, network and storage researchers and information science professionals from University of Michigan / ARC-TS, Michigan State University, Wayne State University, and Indiana University (focusing on SDN and net-topology)

We have a wide-range of science stakeholders who have data collaboration and data analysis challenges to address within, between and beyond our campuses:

High-energy physics, High-Resolution Ocean Modeling, Degenerative Diseases, Biostatics and Bioinformatics, Population Studies, Genomics, Statistical Genetics and Aquatic Bio-Geochemistry
Ceph gives us a robust open source platform to host our multi-institutional science data

- Self-healing and self-managing
- Multiple data interfaces
- Rapid development supported by RedHat

Able to tune components to best meet specific needs

Software defined storage gives us more options for data lifecycle management automation

Sophisticated allocation mapping (CRUSH) to isolate, customize, optimize by science use case

Ceph overview: https://umich.app.box.com/s/f8ftr82smlbuf5x8r256hay7660soafk
OSiRIS Data Infrastructure Building Block

OSiRIS Campus
- 10 to 100G
- More than one path
- More than one wavelength

Campus Network
- 10-100G
- 10G to 4x40G

Wide-Area Network
- In Chicago
- 10 to 100G

GlobusOnline Data Transfer Node
- PowerEdge R630

perfSONAR-PS Network Measurement Node
- PowerEdge R630

Ceph OSD Node (1 to 10 nodes)
- PowerEdge R730xd
- NVMe x 4
- 400-800GB Each
- Head node has 384GB of ram, 40 logical processors, up to 4 NVMe for journaling, 4x25G NICs and two dual port SAS HBAs to connect the JBOD

PowerVault MD3060e
- JBOD holds 60 SAS 8TB disks

Virtualization Node (2 nodes)
- PowerEdge R630
- Libvirt Hypervisor - R630, 256G ram, 2 x 800G NVMe (md raid1), 4x1TB (hw raid-10), 2x25G NIC

Ceph Mon and MDS VMs will be hosted here. Will also host OMD monitoring, development VMs, and science domain-specific VMs as required.
Deploying and extending our infrastructure relies heavily on orchestration with **Puppet and Foreman**

We can easily deploy bare-metal or VMs at any of the three sites and have services configured correctly from the first boot.

*Except: OSD activation requires a manual step*

**Open vSwitch (scripted setup)**
A resilient logging infrastructure is important to understand problems and long-term trends. The 3 node arrangement means we are not reliant on any one or even two sites being online to continue collecting logs. Ceph cluster logs give insights into cluster performance and health we can visualize with Kibana.
We want insight into each layer of our architecture - systems, storage, network, and Ceph itself.

We’ve been able to leverage collectd and its large collection of plugins.

All of our systems feed data to instances of Influxdb and we can plot any series of data with Grafana (examples to follow).
One example - data from collectd-disk plugin focused on one OSD device and its related journal partition as well as the whole device.

Below, collectd-ceph plugin collects stats directly from OSD daemon sockets. We take an average of the latency and group by host.
Because networks underlie distributed cyberinfrastructure, monitoring their behavior is very important

The research and education networks have developed perfSONAR as an extensible infrastructure to measure and debug networks (http://www.perfsonar.net)

The CC*DNI DIBBs program recognized this and required the incorporation of perfSONAR as part of any proposal

For OSiRIS, we were well positioned since one of our PIs Shawn McKee Co-leads the worldwide perfSONAR monitoring effort for the LHC community: https://twiki.cern.ch/twiki/bin/view/LCG/NetworkTransferMetrics

We are working to extend perfSONAR to enable the discovery of all network paths that exist between instances

SDN can then be used to optimize how those paths are used for OSiRIS
The OSiRIS Network Management Abstraction Layer is a key part of managing our network as a dynamic resource.

Captures site topology and routing information in UNIS from multiple sources: SNMP, LLDP, sflow, SDN controllers, and existing topology and looking glass services.

Package and deploy conflict-free measurement scheduler (HELM) along with measurement agents (Basic Lightweight Periscope Probe - BLiPP)

Correlate long-term performance measurements with passive metrics

Defining best-practices for SDN controller and reactive agent deployments within OSiRIS.
Part of our project is also testing the viable limits of Ceph.

We did a variety of scenarios - at left is a plot of gradually increasing latency to a single storage block during recovery to another node. At 320 ms there are major problems. Things don’t really recover fully until we back off to 80ms...likely 80ms is the max safe latency.

Will test at SC16!!
ATLAS will use the OSiRIS Ceph S3 gateway to read/write single events. Allows leveraging transient computing resources - lost job means only 1 lost event. Authentication is still in the early stages - doesn’t yet tie in with ATLAS authentication. Plots of running test event code.
High-level: InCommon participants use their “local” identity and computing resources. VOs self-organize and manage members and roles via OSiRIS services. OSiRIS/Ceph respect membership and roles.

- Session and affiliation data are first pulled into OSiRIS from SAML2 Assertions made by IdPs at configured or InCommon participant organizations
- Valid SAML2 sessions are combined with OSiRIS Access Assertions to create Bearer Tokens that users may use with OSiRIS’ wide array of interfaces / use cases
Still in the early stages of engagement

The Naval Research Lab is collaborating with researchers at UM to share their high-resolution ocean models with the broader community

- This data is not classified but is stored on Navy computers that are not easily accessible to many researchers

Discussions are underway to determine a suitable interface and transfer method to put this data into OSiRIS for wider use

We are exploring S3/RGW with objects mapped to a URL to provide high-level organization of the objects (e.g., the URL defines the type/location of the object data)
The OSiRIS project goal is enable scientists to collaborate on data easily and without (re)building their own infrastructure. The science domains mentioned all want to be able to directly work with their data without having to move it to their compute clusters, transform it and move results back. Each science domain has different requirements about what is important for their storage use-cases: capacity, I/O capability, throughput and resiliency. OSiRIS has lots of ways to tune for these attributes.
Questions or comments?

Some conclusions on Ceph and latency (also see [http://www.osris.org/performance/latency](http://www.osris.org/performance/latency))

When latency to any OSD host hits 160ms RTT, throughput and ops are effectively 0. Before this point we see a steady and predictable decrease from the maximum but still usable.

Max RTT latency to any given OSD is probably about 80ms. Beyond this recovery ops may not be reliable.

Ceph Monitors are not particularly sensitive to latency. At up to 800ms RTT to one monitor there were not any issues and cluster ops, including mon ops such as creating auth keys, were fine. Somewhat slower for some interactive ops.

We didn’t try to adjust any timeouts, etc upward to compensate, but this may be possible.
OSiRIS Access Assertions: Overview and Lifecycle

Central Authority

Authenticated Actor (AA) Asks Central Authority (CA) to generate an OSiRIS Access Request (OAR) for a given resource on their behalf.

CA chooses a Resource Authority (RA), produces and sends an OAR on behalf of the AA based on Central OSiRIS affiliation rules/data.

The OAG can contain information that is opaque to the Authenticated Actor and CA such as passwords and de-provisioning scripts instructions.

The OAG’s signature is checked and is added to a final credential, the OSiRIS Access Assertion (OAA) that when combined with a current and valid InCommon session is usable for authentication into and de-provisioning of any resource provided by any participating resource provider. The OAA is stored on the CA on behalf of the AA until it expires or becomes otherwise invalid.

Resource Authority

Authenticated Actor

RA evaluates the OAR to decide on handling it and what actions need to be taken. provisioning and/or configuration should occur here.

If the OAR checks out / meets RA specific affiliation rules, the RA generates and sends an OSiRIS Access Grant (OAG) to the CA
Scientific Linux 7.2
Ceph 10.2.3 (aka Jewel)
Puppet 3.8.7 with future parser enabled
Foreman 1.10.4
Influxdb 1.0.2
Grafana 3.0.4 (bc 3.1.1 had a stopper templating bug for us, waiting for 3.1.2 with bugfix)
Elasticsearch 2.4.1
Kibana 4.5.4
Logstash 2.3.4
Filebeat 1.3.1 (client log shipper)
Check_mk raw/client 1.2.6p16
openvswitch 2.5.0 (RPM built locally)
mlnx_en drivers 3.3 (RPMs built locally with nightly check if need to build vs new kernel versions in SL or ELrepo)

On xfer gateway hosts we use kernel-lt-4.4.22 from ELrepo so we can mount cephfs in-kernel (or whatever is latest, we don't pin to any one version). Theoretically this is so they have the fastest possible access to CephFS for Globus transfers. When Redhat mainlines CephFS support into the stock kernel we'll stop doing this.

Most of the libvirt/qemu tools from stock SL repos, these exceptions were pulled in from the CentOS Virt Special Interest Group repository (SIG). These updated packages let us take live snapshots and live merge changes back into those snapshots later. The purpose is live backups of running VMs into our own fuse mounted CephFS (maybe we get credibility points for that since nobody else is using our cluster yet).
