Beam position monitoring

Resolver Position

VELO Monitoring

Results on TED data

- ❄ No cosmics for VELO!
- ❄ First TED data extremely valuable:
 - ✦ Timing study
 - ✦ Reprocessed data results
 - ✦ First module alignment
- ❄ Data taken on August and September
- ❄ About 410 events with about 1400 tracks

Friday 22nd August 2008

- ❄ Powered HV channels of 10 modules:
 - ✦ 5 modules on A side
 - ✦ 5 modules on C side
- ❄ 2 Runs with about 80 tracks

Sunday 24th August 2008

- ❄ Powered all HV channels
- ❄ TELL1 on for 76 sensors
- ❄ 5 Runs with about 700 tracks
- ❄ Mixture of ZS and NZS+ZS data

5th and 6th September 2008

- ❄ Powered all HV channels
- ❄ TELL1 on for 76 sensors
- ❄ 16 Runs with about 700 tracks

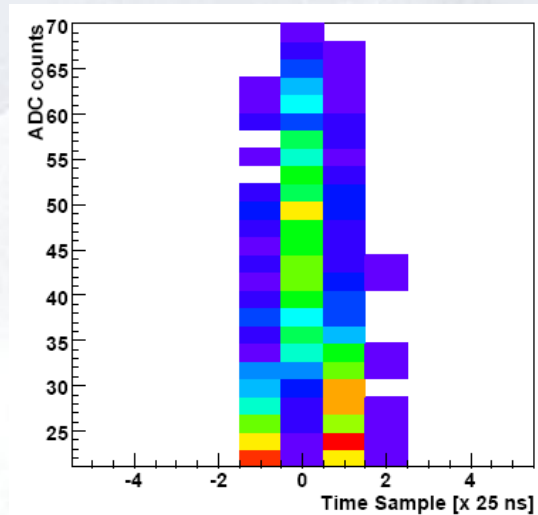

Timing for individual sensors

- ❄ 15 consecutive triggers
- ❄ ADC counts collected in a cluster versus the time sample

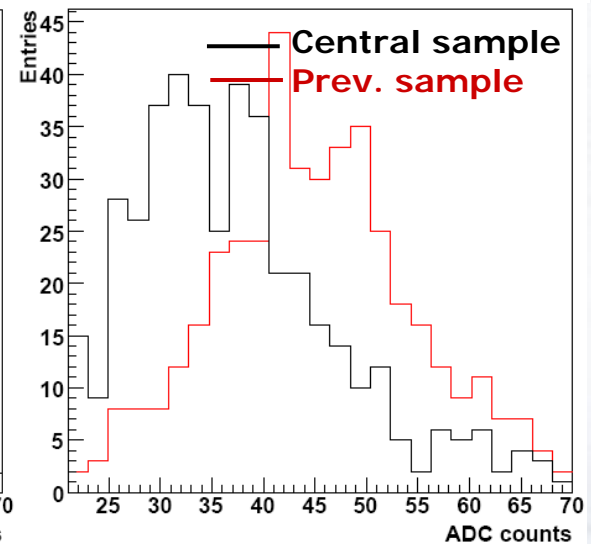

Different Timing
for the sensors
⇒ inefficiency at
reconstruction

Automated timing scan
procedure developed
and being tested.

R Sensor 0

R Sensor 30

Data Taking configuration

❄ All TELL1 parameters were not tuned

❄ We observed the following effects:

- * Noisy strips
- * Inefficiency in some sensors
- * Timing not optimized for all the sensors

❄ Few runs with about 30 events with ~70 tracks taken also in non-zero suppressed mode

➡ they can be reprocessed with a different configuration:

- * Introduced Beetle header correction
- * Subtracted fixed pedestal bank after a proper training on noise data
- * Evaluation of seeding thresholds for each individual strip

Data taking period	August/September
Number of Tracks	About 700
TELL1 configuration	
Pedestal correction	Const for all channels
Cable Cross talk filter	Off
Beetle header Cross talk correction	Off
Mean Common mode	Off
Reordering	On
Linear Common mode correction	On
BEETLE parameters	
$V_{\text{feedback shaper}}$	1000/500
Clusterization	
Seeding threshold (high threshold)	Const for all channels
Inclusion threshold (low threshold)	Const for all channels
Spillover threshold (sum threshold)	Const for all channels
Maximum number of cl. per sens.	1020 per sensor

Reprocessed data with new TELL1 configuration

Multiplicity of points associated to a track in A side

□ No TELL1 tuning
■ With TELL1 tuning

Multiplicity of points associated to a track in in C side

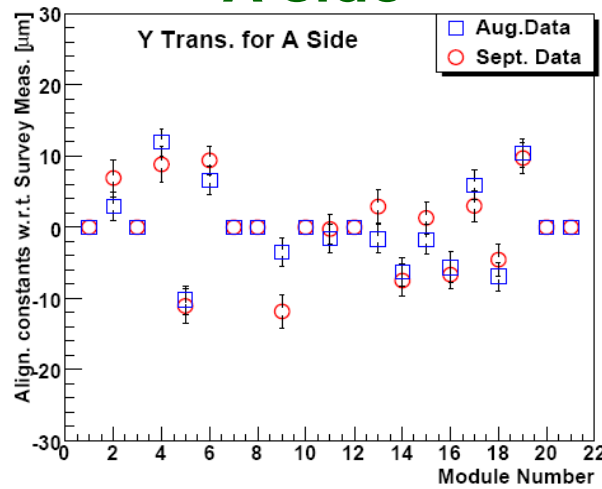

Alignment results for TED data

- ❄ **Alignment results using TED data:**
 - ✦ **Metrology for Sensors and Modules as input**
 - ✦ **Module alignment for X, Y translation and Z rotation**
 - ✦ **No sensor alignment**
 - ✦ **Turn off the 3 modules with a very low statistics**

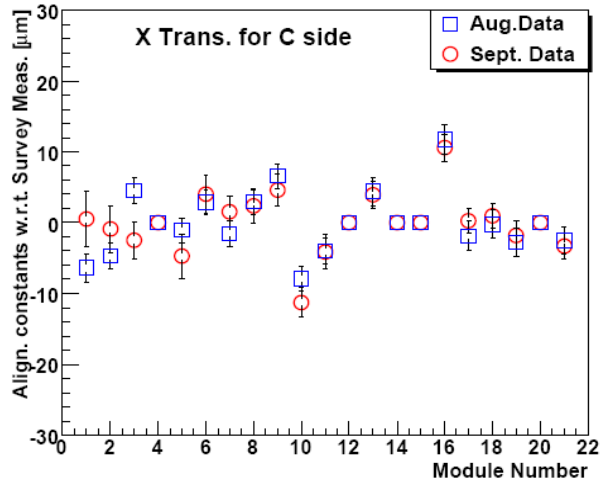

- ❄ **Comparison of alignment constants evaluated by different methods using Aug. and Sept. data samples:**
 - ✦ **Millepede considering X & Y trans and Z rot,**
 - ✦ **Millepede considering X & Y trans.,**
 - ✦ **Kalman considering X & Y trans.**

VELO Alignment

❄ Evaluation of Alignment constants by a method based on Millepede using as input

1. NoModMetr

- ★ No Metrology for the modules
- ★ Metrology for the sensors

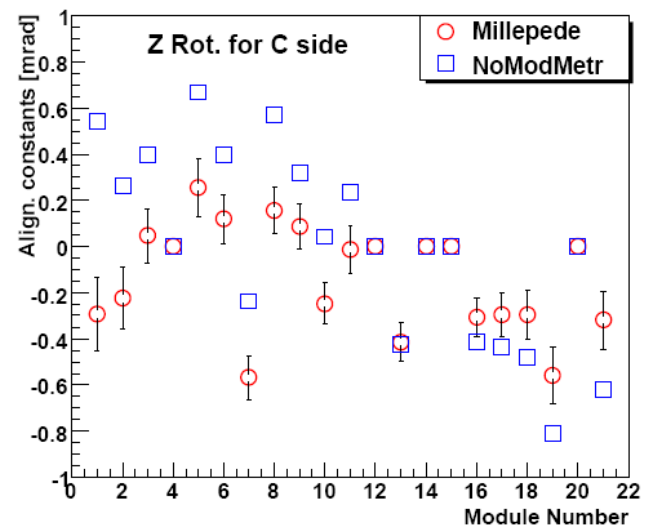

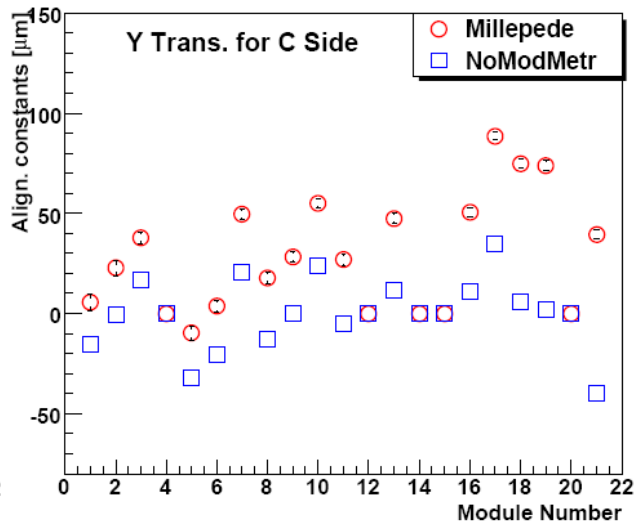

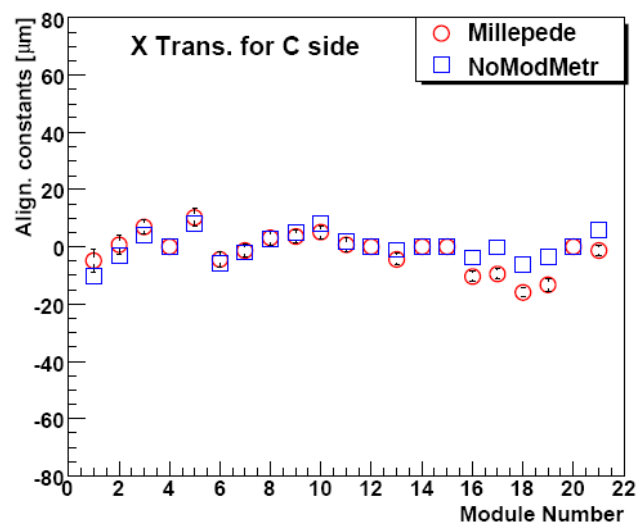

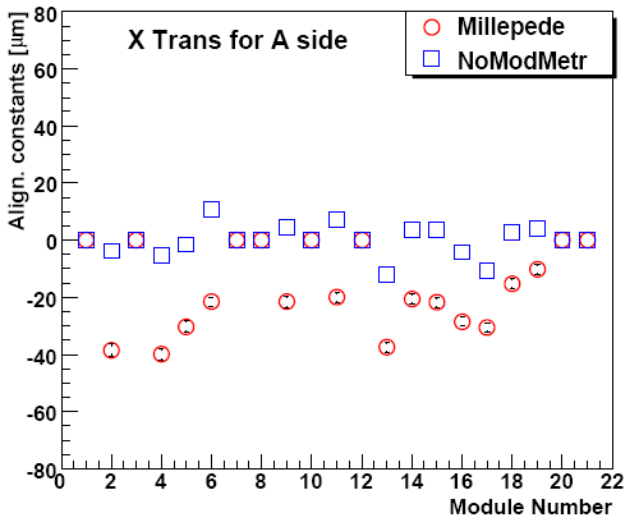

2. Millepede

- ★ Metrology for the modules
- ★ Metrology for the sensors

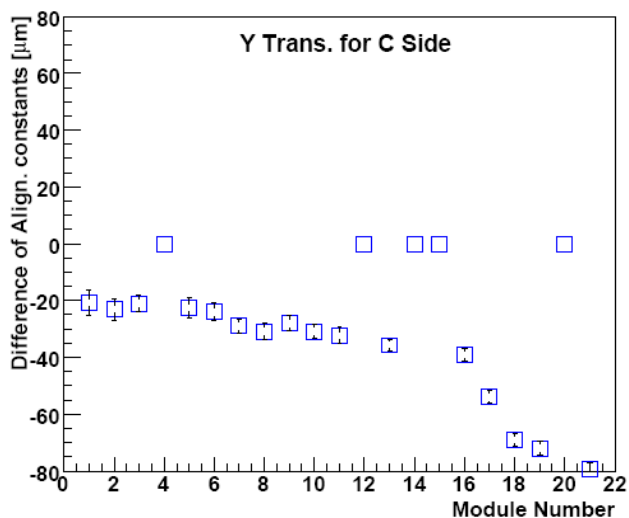

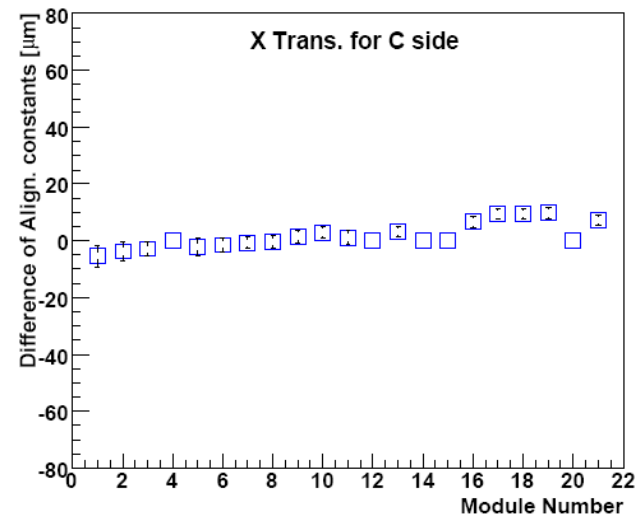

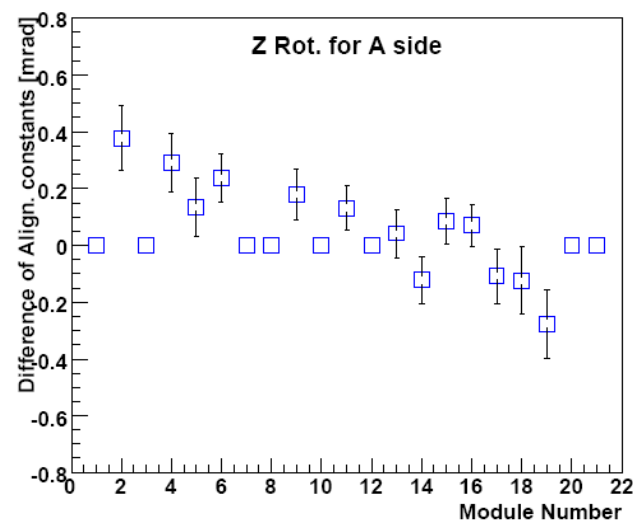

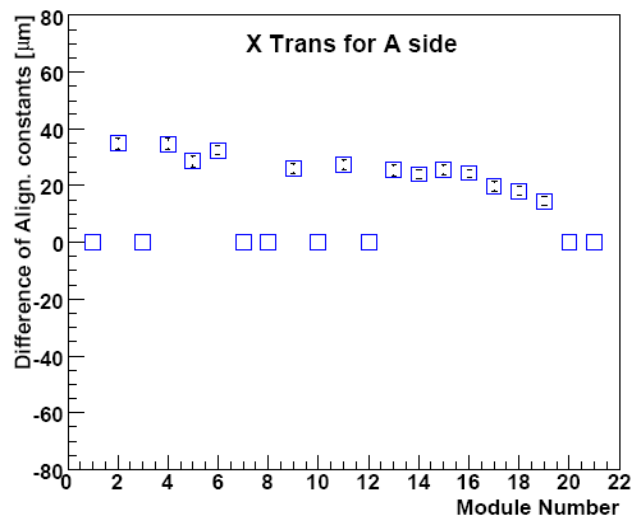

❄ Alignment for X and Y translation and Z rotation

❄ Data Sample: September TED data

Comparison of Alignment constants

Difference of Alignment constants

Global shift or rotation

❄ Module alignment fixes the average position of the modules

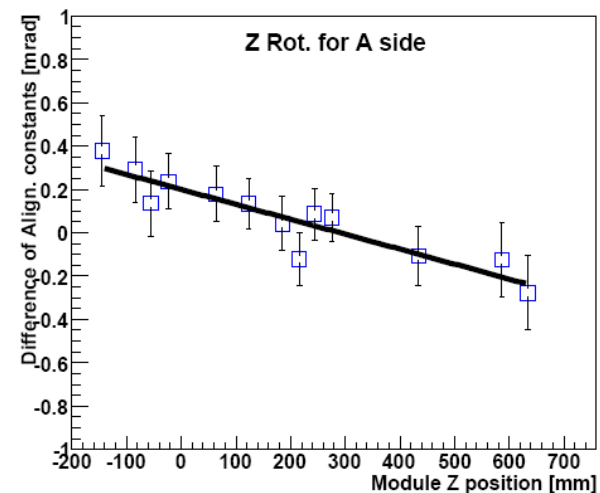

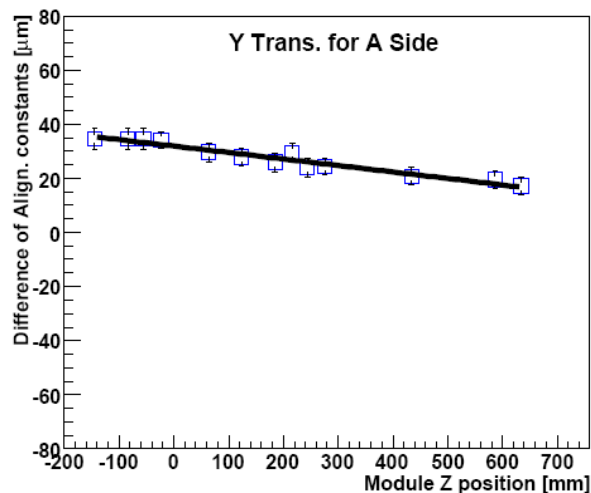

❄ Module alignment cannot determine a systematic shift that can be justified as a global shift or a global rotation

❄ One should evaluate the difference after the subtraction of the global shift or global rotation

Extract the global component

Difference of alignment constants excluding the global component

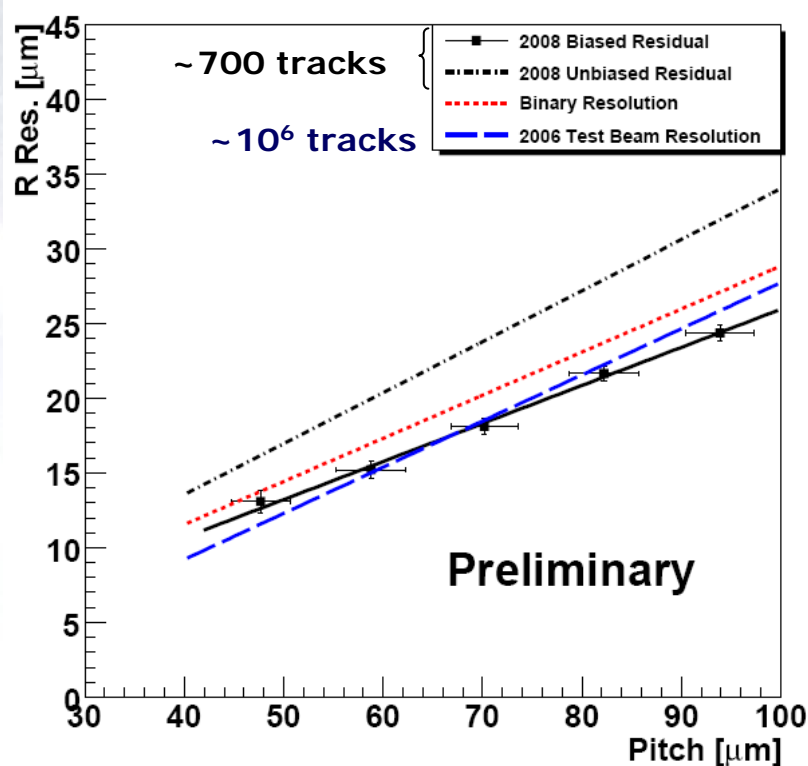

Conclusion on VELO alignment with TED data

- ❄ Alignment constants evaluated by different methods using Aug. and Sept. data samples
 - * Millepede considering X & Y trans and Z rot,
 - * Millepede considering X & Y trans.,
 - * Kalman considering X & Y trans.
- ❄ Evaluation of alignment constants with and without Metrology measurement for modules as input.
- ❄ The detector displacement from metrology is less than $10\ \mu\text{m}$
- ❄ The differences on the translation constants between the two data samples (August and September) are of the order of few microns, up to $10\ \mu\text{m}$ in few cases for both methods (and about $200\ \mu\text{rad}$ for Z rot, if applied).
- ❄ Module alignment precision is $5\ \mu\text{m}$ for X and Y translation and $200\ \mu\text{rad}$ for Z rotation
- ❄ Results presented in previous alignment meetings:
 - * 12 November 2008
<http://indico.cern.ch/getFile.py/access?contribId=6&resId=0&materialId=slides&confId=43986>
 - * 12 December 2008
<http://indico.cern.ch/getFile.py/access?contribId=100&sessionId=12&resId=0&materialId=slides&confId=44134e>

➔ Note in preparation

Residual on September sample

- ❄ The unbiased residual overestimated the resolution due to the extrapolation error
- ❄ The biased residual underestimated the resolution
- ❄ TELL1 parameters configuration and the timing not optimized for all the sensors: the percentage of 1 strip cluster is about 85%
 - ➔ the expected resolution is the binary one.
- ❄ Improvement expected when the TELL1 tuned parameters are applied and the proper timing calibration is determined

*Beam position monitoring
in the closing procedure*

VELO closing implementation - Malcolm John

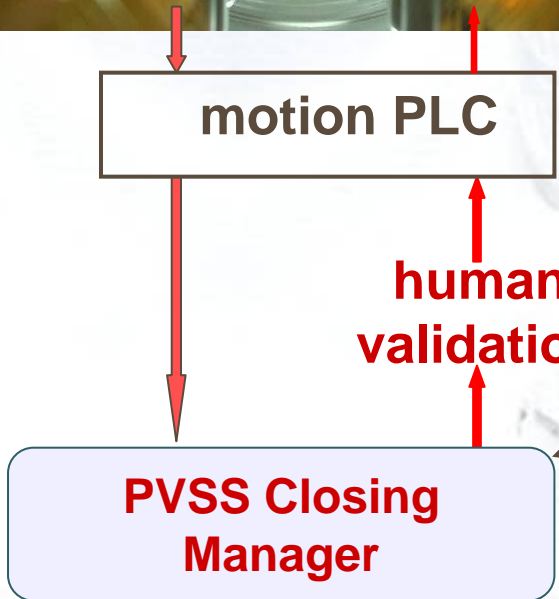

HLT farm

- 3D vertex reconstruction
- Two lines: VeloASideDecision, VeloCSide Decision
- Uses only standard PR + vertexing packages

↓ Triggered RawEvent

Online Monitoring

- Fill Histograms
- Calculate and suggest next VELO position
- Generate parsing XML
- Calculate validation data (e.g. VELO residuals)

PVSS data-points

CondDB

Closing: Performance

- ❄ The triggered object (the vertex) is stored in the RawEvent via the HltVertexReport class
 - ✦ This object is decoded in the online monitoring and histogrammed
- ❄ Histogram available via DIM
- ❄ Key information (mean, RMS etc...) published regularly to DIM.
 - ✦ Observe 2s refresh rate in PVSS
- ❄ At nominal luminosity, the time to reconstruct the luminous region and take a decision is negligibly small compared to the motion.
- ❄ At $L=10^{28} \text{ cm}^2\text{s}^{-1}$ and $\sqrt{s}=900\text{GeV}$, get 70Hz of useful vertices in the open position.

VELO fully open; $L=10^{28}\text{cm}^2\text{s}^{-1}$

PVSS closing manager

Real-time vertex monitoring

Resolver measurement

LHC beam position information at IP8

Silicon bias current

BCM relative flux

Performs consistency checks between motion and measurements as well as monitoring the key hardware.

Its output can be:

- Retract and park!
- Request human!
- Move to new position!

 2008.08.25 15:42:53.873 All criteria enabled are OK.

Close

Data from vertices vs data from resolver

Real Position of the Velo
 Example: beam is at x=1 mm

A side resolver

Software calculated distance to nominal

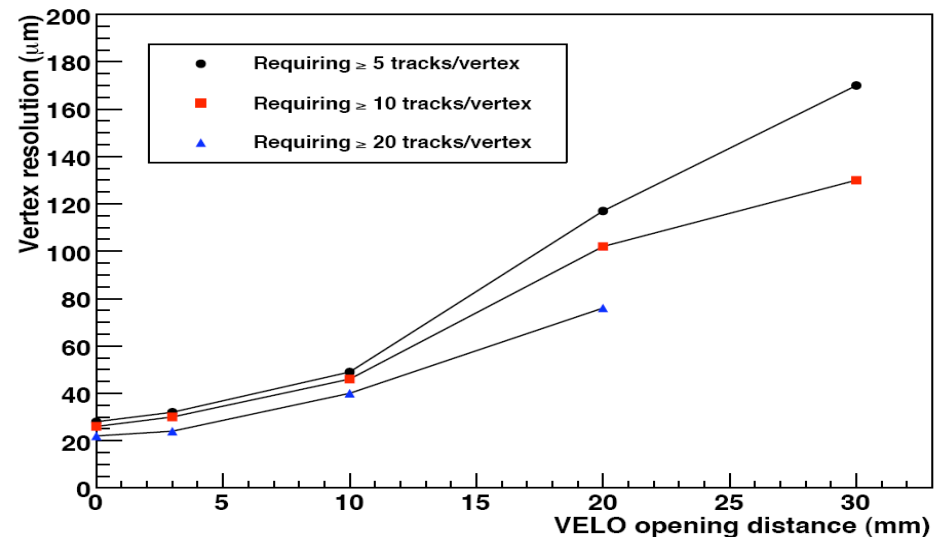

sanity cross check: $XA - XC$ must equal $dtmA + dtmC$
opening as measured with resolvers = opening as measured with software

Control plots used during closing

- ❄ Resolver measured opening vs software measured opening
- ❄ Change in position and total opening as
 - ❄ asked to motion control system
 - ❄ measured by resolvers
 - ❄ measured w.r.t. beam
- ❄ Reconstructed position of beam in LHCb coordinates
 - ❄ needs software and resolver information
 - ❄ Here we are looking for stability and correspondence with BPMs
- ❄ When we are close
 - ❄ reconstructed opening distance from vertices vs reconstructed opening distance from overlaps
- ❄ The required tolerance will change as we approach

in x and y
independently

Vertex resolution vs. VELO opening

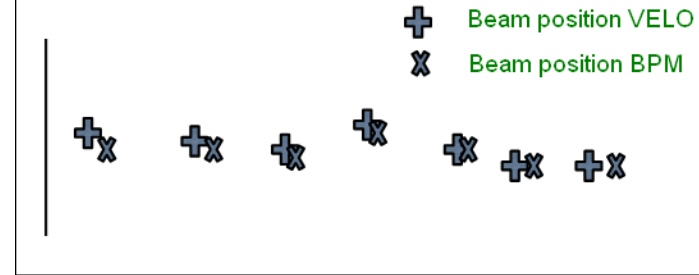

Principal control plots (examples):

Distance to vertex

Beam position

occupancies

currents

etc...

Distance A side - C side

BCM

luminous region

etc...

Status and Plan

- ❄ Demonstrate using decoding HltVertexReports in the online monitoring (January)
- ❄ Demonstrate complete chain from HLT input to motion control with FEST data (February)
- ❄ Critically review / improve monitoring plots, PVSS interface and human interface (March)
- ❄ System check-out (April 1st)
- ❄ Extensions: More algorithms.... overlap, cross-checks.

Resolver position

Motion System Summary

- ❄ Three pieces of information available (through PVSS):
 - ✦ Steppermotor (number of pulses sent)
 - ✦ Resolver measurement
 - ✦ Potentiometer reading (detector safety system - 0.1mm accuracy)

- ❄ Motion accuracy for resolver position:
 - ✦ Position accuracy about $\sim 10 \mu\text{m}$
 - ✦ Position reproducible (moving in the same direction) $\sim 3 \mu\text{m}$

- ❄ In x:
 - ✦ Steppermotor sends 2000 pulses for $50 \mu\text{m}$ (1:40 gearing)
 - ✦ 1mm in 9 seconds; i.e. $4\frac{1}{2}$ minutes to drive 30mm
 - ✦ Open position is at $|x|=29\text{mm}$
 - ✦ Each half can drive up to 5mm beyond nominal $x = 0$

- ❄ In y:
 - ✦ Steppermotor sends 2000 pulses for $250 \mu\text{m}$ (1:16 gearing)
 - ✦ 1mm in 3 seconds
 - ✦ Motion in y is only possible for $|x|<16\text{mm}$
 - ✦ Range is $-4.7 < x < 4.7 \text{ mm}$

Alignment information in Condition Database

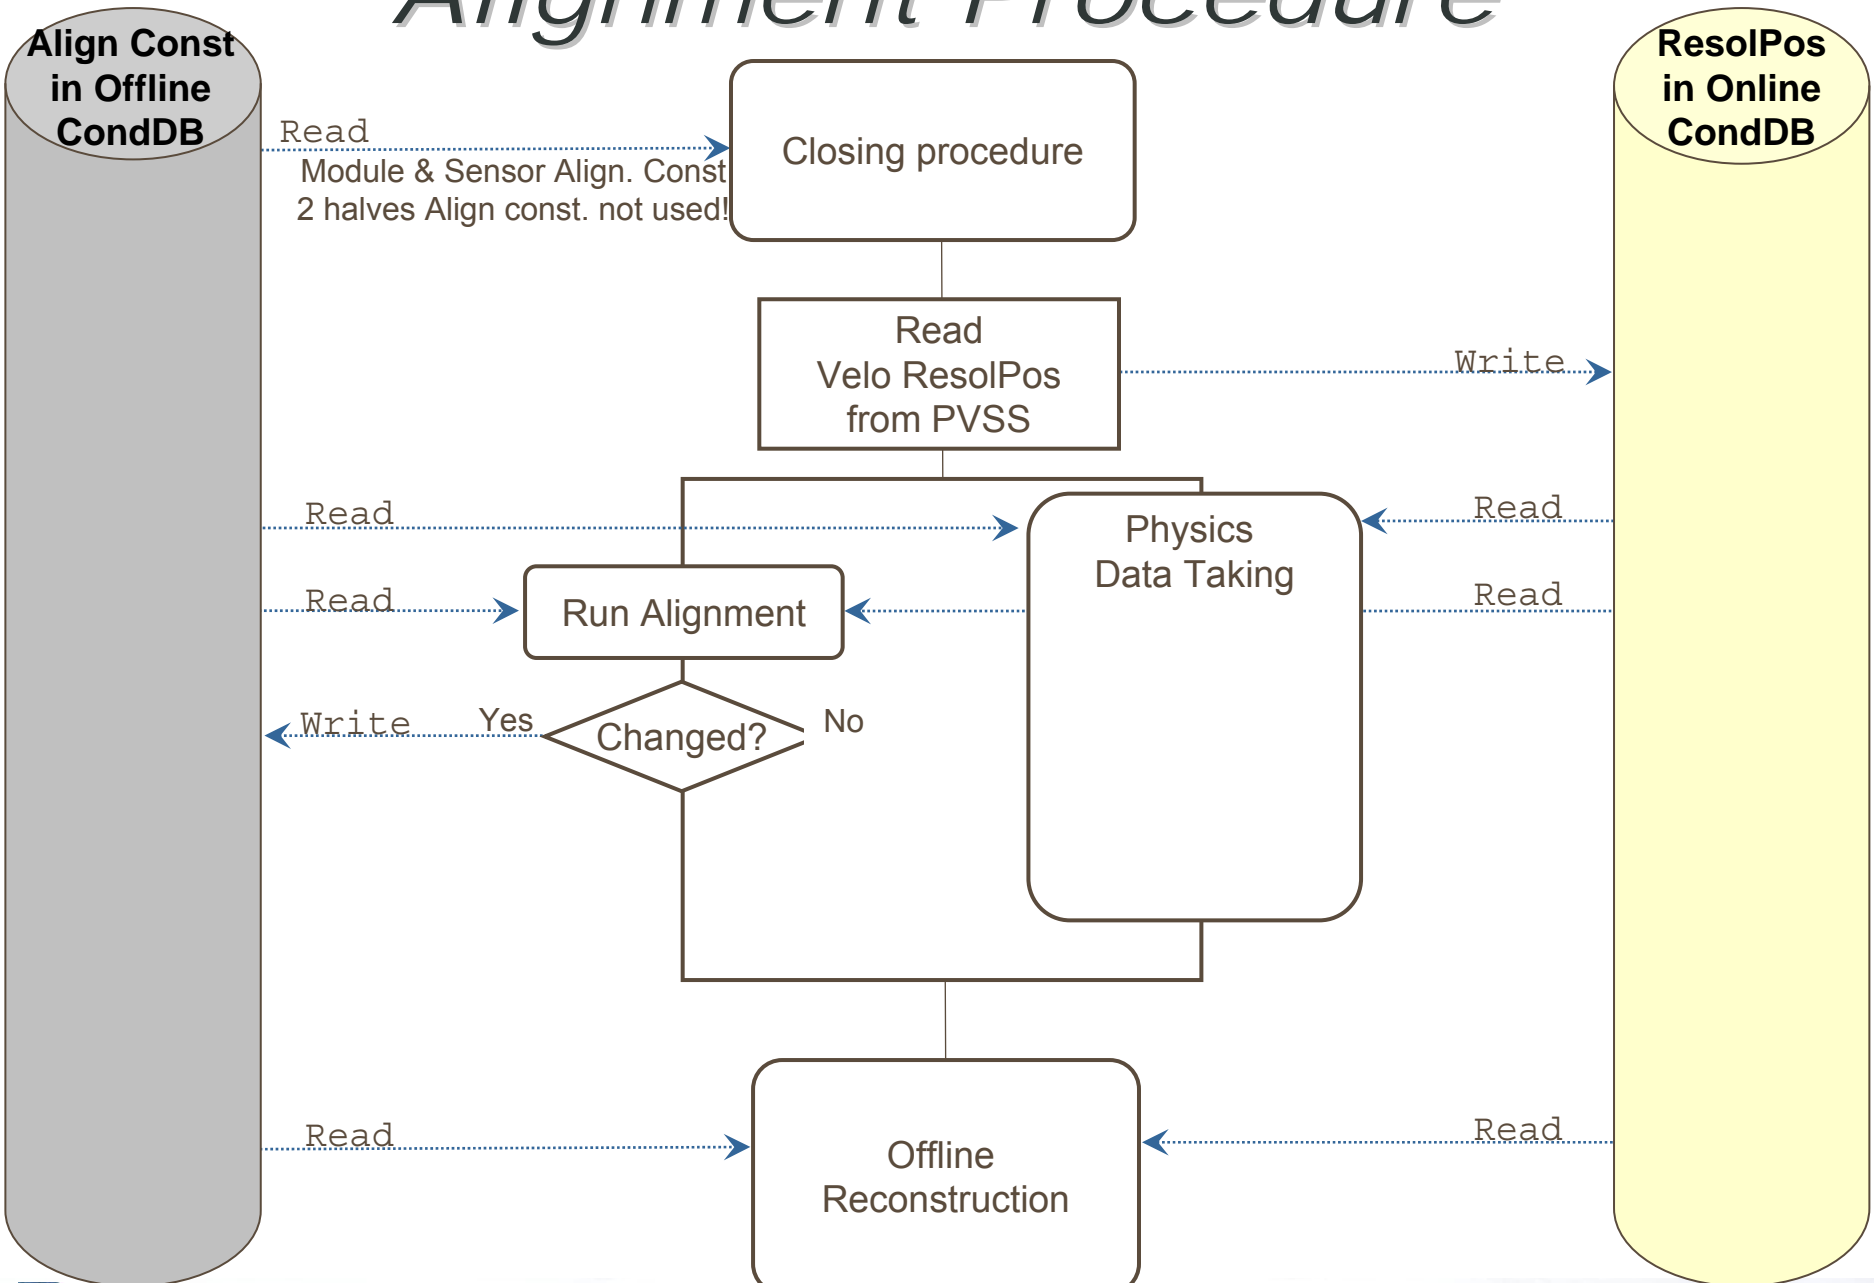

- ❄ Alignment constants in 3 files:
 - * Sensor, Module, Global

- ❄ Initial alignment from metrology measurements carried out at Liverpool and CERN.
 - * Sensor, Module, Vacuum Tank

- ❄ **Resolver position from the motion system for x and y position of each VELO half**
 - * It is automatically update into online CondDDB at beginning of run if it is changed from the previous one
 - * It is used by the HLT
 - * It is automatically update into a private CondDDB each time it changes

- ❄ VELO position used in the reconstruction in LHCb reference system is determined by a function that combines the Alignment constant and the resolver position (transparent for the user)

Alignment Procedure

VELO Monitoring

VELO Monitoring

❄ Monitoring package

✦ Package for “high-level” (= ZS) data [VeloRecMonitors]

✦ Monitoring based on clusters [VeloClusterMonitor alg. in Velo/VeloRecMonitors]:

Cluster ADC value, active chip links, number of strip in a cluster, cluster ADC value versus sampling, number of cluster per events, more...

Some of these distributions versus sensor number and/or sensor strip

✦ Monitoring based on tracks [VeloTrackMonitor alg. in Velo/VeloRecMonitors]:

Number tracks, pseudo-rapidity, azimuthal angle, pseudo-efficiency, biased and unbiased residuals versus sensor number, vertex information, hits distribution in xy and xz, more...

✦ Package for NZS data [VeloDataMonitor]

✦ Noise calculation, time alignment study, beetle pulse shape, ...

❄ Scripts and macros are being developed to analyse data:

✦ Time alignment study,

✦ Noise calculation,

✦ High voltage scan,

✦ More...

❄ Wiki pages with documentation and HowTo's:

<https://lbtwiki.cern.ch/bin/view/VELO/VELODataQuality>

VELO alignment monitoring

Online monitoring:

- ❄ Residual distribution for each sensor
- ❄ Overview: Residuals versus sensor number
- ❄ Histogram of Mean and RMS of residual distribution for each sensor

Overview of the offline monitoring:

- ❄ Measure size of misalignment from residual vs Φ distribution
- ❄ Analyse the plots by fitting sinusoidal functions using python scripts
- ❄ Script has two levels: warnings and alarms
- ❄ Warnings are counted
- ❄ Alarms are counted and printed for each module that causes an alarm
- ❄ Thresholds depend on fit values (\approx misalignments) and their significances
- ❄ Produce overview plots of both

Traces of a 'Gauss bug' in only 98 events

Misalignment

Significance

Without
Metrology

With
Metrology

VELO alignment monitoring

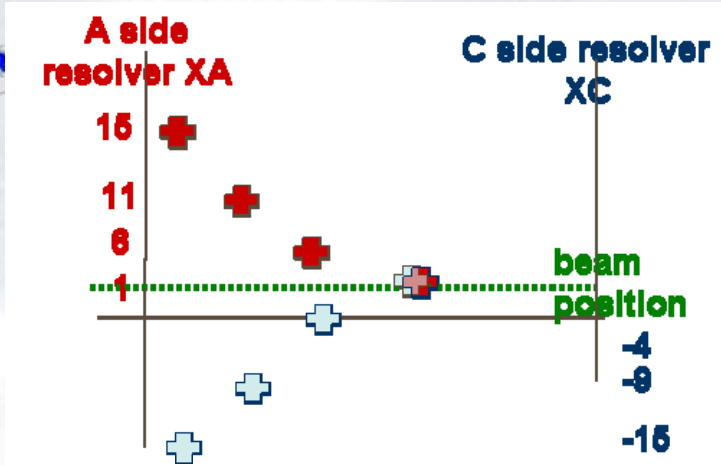

Monitoring of the VELO half alignment

- ❄ Monitor VELO half alignment through primary vertices by Offline PV Tool
- ❄ Reconstruct PV position with tracks of only one half at a time
- ❄ Plot A and C side PV position
- ❄ Plot A-C side 2D difference in PV position
- ❄ To be implemented in parallel with changes to alignment code

Backup

Closing procedure

Some interesting closing moments I: Tracks linking A&C

1. Overlaps of sensitive regions:

nominal-2.9mm

ϕ sensors in every
other station touch corners
(Can we use this?)

nominal-1.7mm

R sensors start
to give overlap:
measure of y and
in small regions x

nominal-400 μm

Overlaps in all
4 sensor orientations
and along ϕ strips.

2. Tracks passing from A side to C side

Powerful measure of separation
Useful at close distances

Vertex resolution

X

$$\sigma_x = 100 \mu\text{m}$$

Y

$$\sigma_y = 100 \mu\text{m}$$

Z

Using info
of one
VELO-half
@ $x=20 \text{ mm}$

20k min-bias
 $N(\text{trks}) \geq 10$
 $\chi^2(\text{vtx}) \leq 10$

$$\sigma_{\text{beam}} = 70 \mu\text{m}$$

Alignment Method

1. Sensor alignment

- ✧ An iterative approach based on residuals
- ✧ Do separate fits to residual distribution as function of phi and r (uncorrelated to first order)

$$\varepsilon = -\Delta_x \cos\phi_{\text{track}} + \Delta_y \sin\phi_{\text{track}} \quad (\text{R sensor})$$

$$\varepsilon = \Delta_x \sin\phi_{\text{cluster}} + \Delta_y \cos\phi_{\text{cluster}} + \Delta\gamma r_{\text{track}} \quad (\Phi \text{ sensor})$$

- ✧ Extract the misalignment constants:
 - ✧ x and y translation
 - ✧ rotation around z axis

2. Module alignment

- ✧ Alignment via MILLEPEDE
- ✧ Minimisation done with single matrix inversion
- ✧ Extract the misalignment constants:
 - ✧ x, y, z translation
 - ✧ rotation around x, y, z axis

3. Velo half alignment

- ✧ Alignment via MILLEPEDE
- ✧ Minimisation done with single matrix inversion
- ✧ Extract the misalignment constants:
 - ✧ x, y translation
 - ✧ rotation around x and y axis

For more details see notes LHCb-2005-101, LHCb-2007-067 and LHCb-2007-138
