

Fast Kalman Track Fit in HLT1 & validation of Lite Clusters

Johannes Albrecht

**Physikalisches Institut
Universität Heidelberg**

Content:

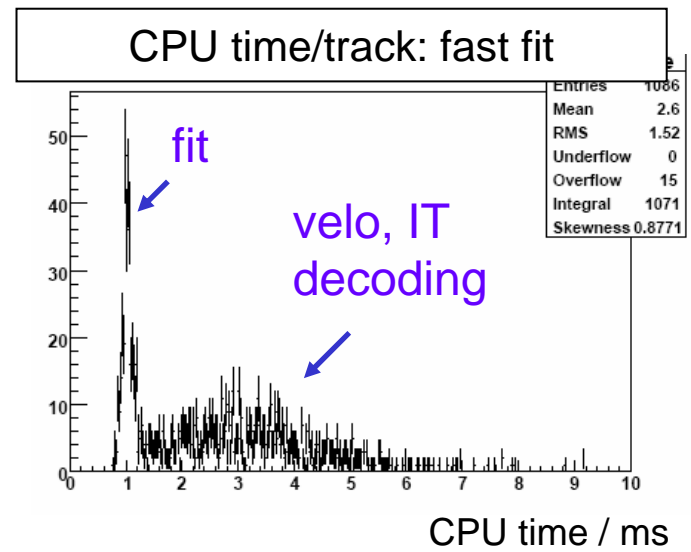

- fast track fit
- validation of lite clusters
- use of fit in HLT1

Reminder: Fast Track Fit

- Use kalman fit with fast options:
 - simplified geometry
 - Only 1 iteration, one direction
 - no outlier rejection, smoother
- Fast fit has shown to be very useful in HLT1
 - muon alley: J.A. TRec Oct.6
 - hadron alley: X.C.Vidal, Dec.15
- Problem: decoding for full Velo, IT/TT clusters

Thanks to Wouter
for help in the
implementation

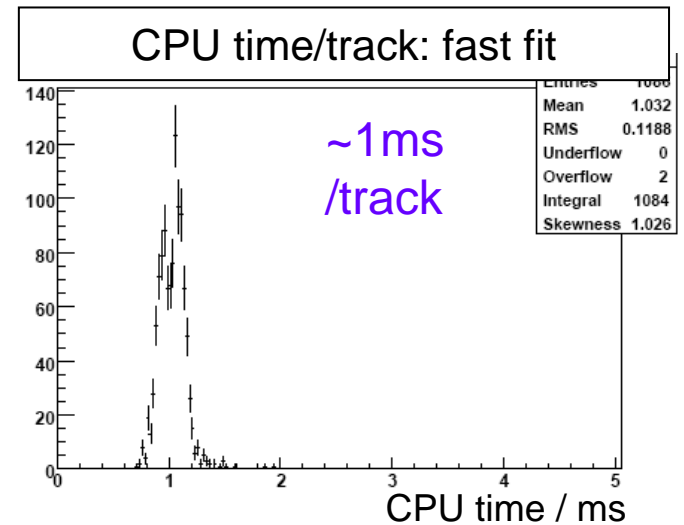

time measured on 1.95 * 2.8 GHz Xeon

Reminder: Fast Track Fit

- D. Hutchcroft (Velo), M. Needham (IT,TT) prepared the fit to use lite clusters
- With slight modifications, the MeasurementProvider can now handle them
- Fit now runs on Velo&IT Lite clusters
 - ~1ms/track
 - validate results with lite clusters

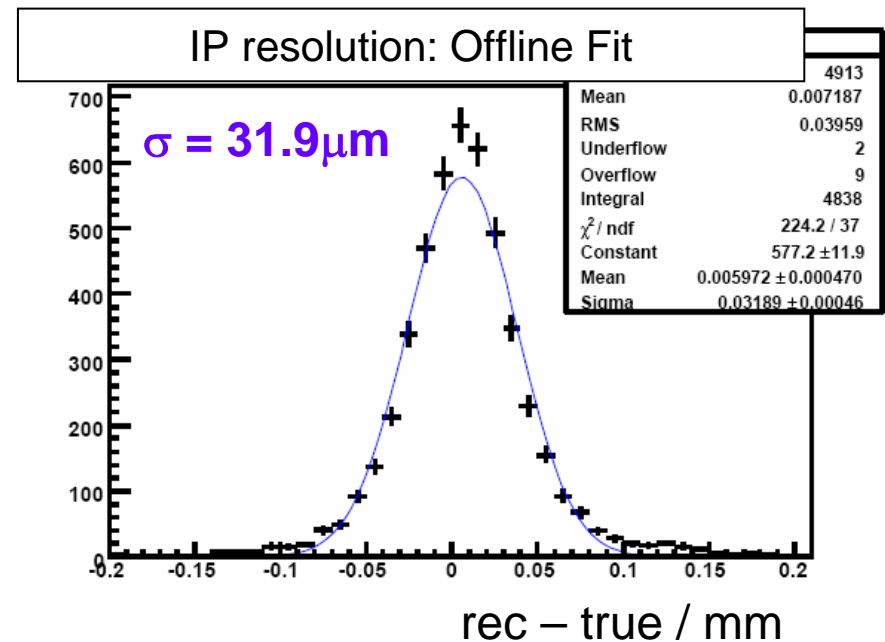

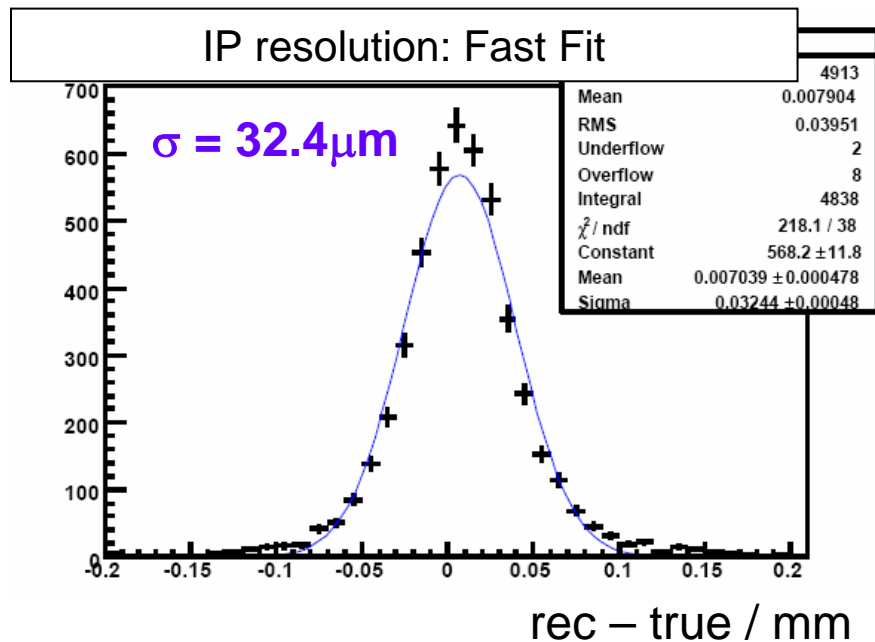

Software versions:

- DaVinci v22r0 plus head of:
 - Event/TrackEvent
 - Kernel/LHCbKernel
 - Tr/TrackFitEvent
 - Tr/TrackFitter
 - Tr/TrackInterfaces
 - Tr/TrackMonitors
 - Tr/TrackProjectors
 - Tr/TrackTools
 - Velo/VeloDAQ
 - Velo/VeloTools

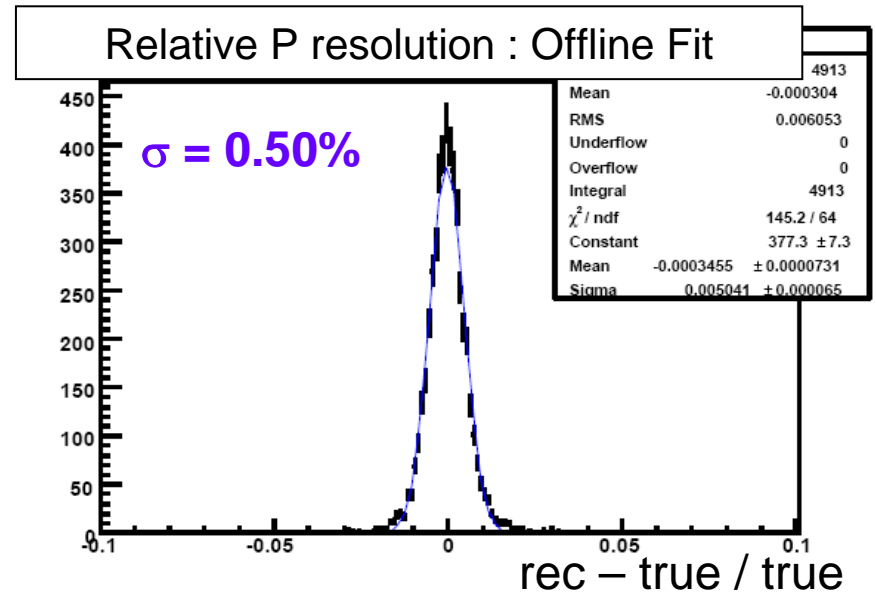

Validation of Lite Clusters: IP

- Use offline selected $B_s \rightarrow J/\psi(\mu\mu)\phi$ events
- Tracks in HLT1 after single muon decision
- Compare IP, p , pt , χ^2 of fast fit w/ lite clusters and offline

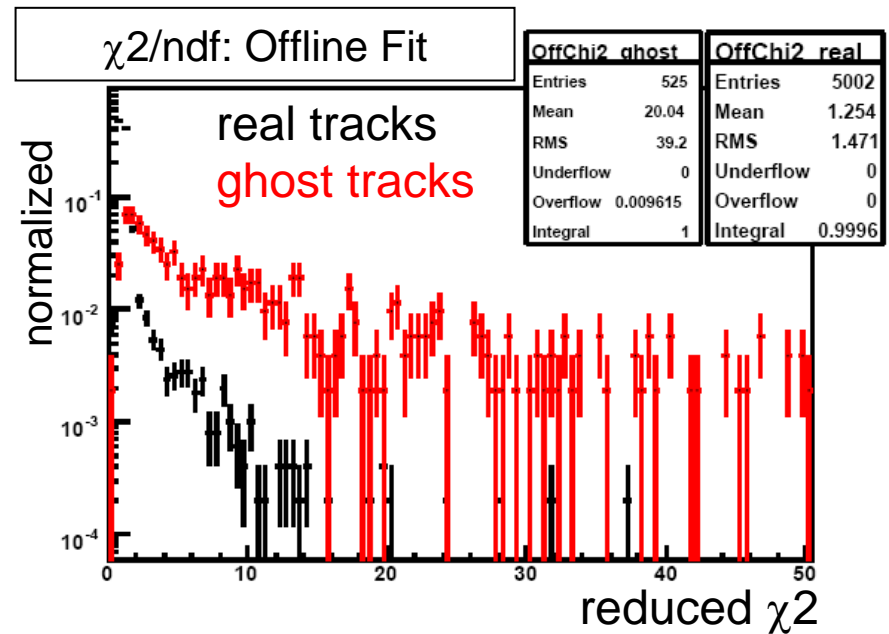

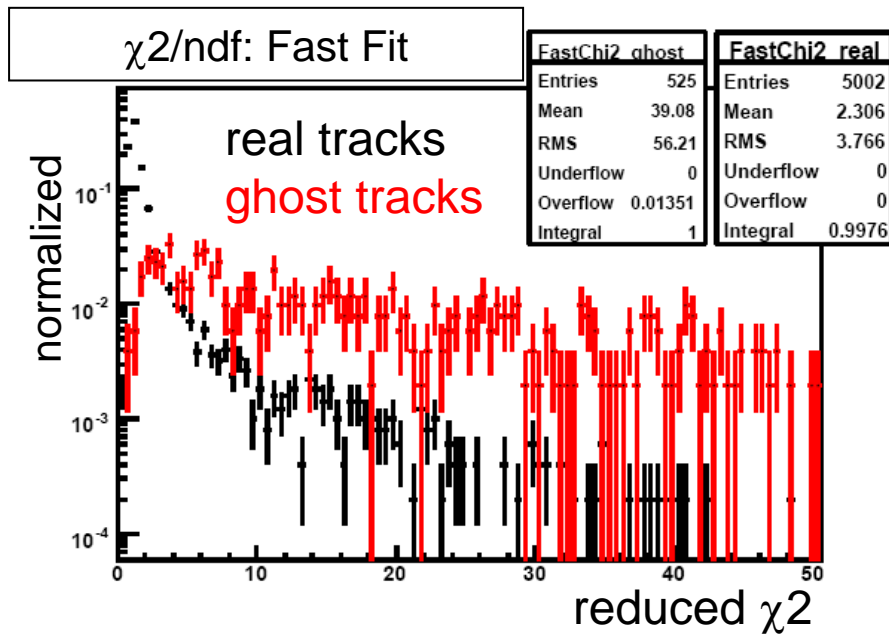

Validation of Lite Clusters: P, PT

Ghost Identification

- Use track fit χ^2 to separate real tracks (more than 70% of hits from same MCParticle) from ghosts

- Good separation between ghosts and real tracks
→ However, some outliers in fast fit

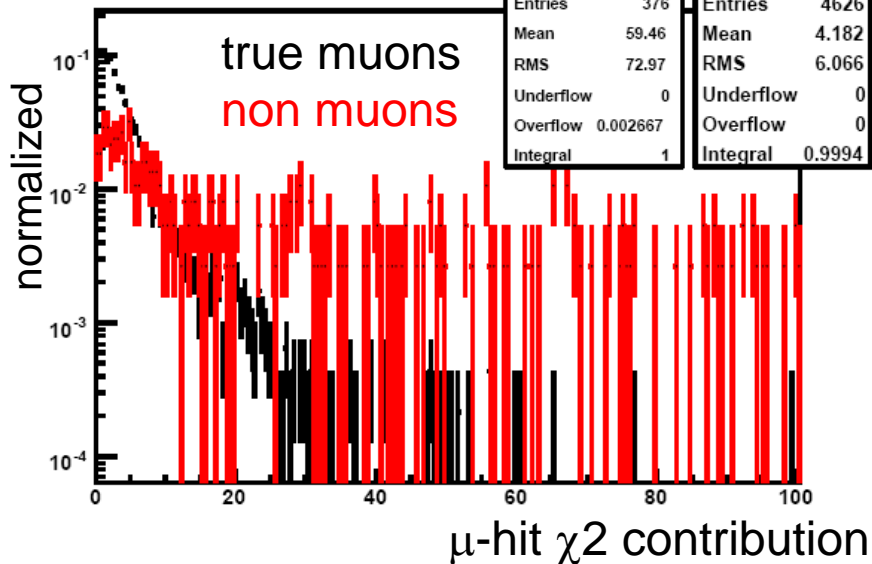

Muon Identification

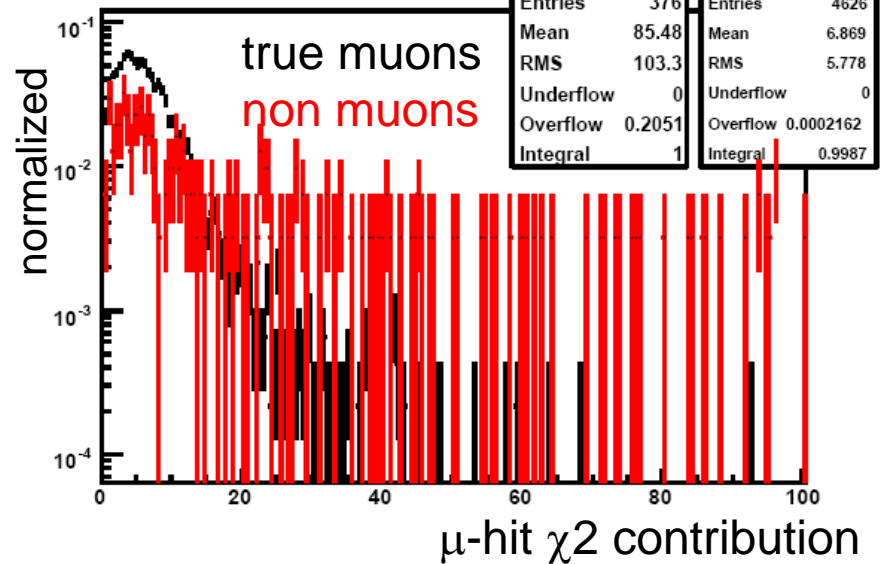

- Use muon hit contribution to χ^2 for muon ID
- The fit performs an excellent muon ID!

Muon hit χ^2 : Fast Fit

Muon hit χ^2 : Offline Fit

Summary

- **Velo, IT and TT Lite clusters are ready to be used in the simplified track fit**
- Tracks (in HLT1) can be fitted within ~ 1 ms/track
- IP, p and p_t resolutions hardly degraded with fast fit
 - however, χ^2 distributions have bigger tails
