# LONGITUDINAL DYNAMICS RECAP

Frank Tecker
CERN, BE-OP

The CERN Accelerator School

Advanced Accelerator Physics Course
Egham, UK, 3–15/9/2017

Summary of the 2 lectures:

• Acceleration methods
• Accelerating structures
• Linac: Phase Stability + Energy-Phase oscillations
• Circular accelerators: Cyclotron / Synchrotron
• Dispersion Effects in Synchrotron, Transition
• Stability and Longitudinal Phase Space Motion
• Stationary Bucket
• Injection Matching
• Hamiltonian

Including selected topics from other CAS lectures :
• Linacs - *Alessandra Lombardi*
• RF Systems - *Erk Jensen, me*
• Timing, Synchronization & Longitudinal Aspects - *Heiko Damerau*
• Electron Beam Dynamics - *Lenny Rivkin*
Continued by
• Beam Instabilities – Longitudinal – *Kevin Li*

Particle types and acceleration

The accelerating system will depend upon the evolution of the particle velocity:
· electrons reach a constant velocity (~speed of light) at relatively low energy
· heavy particles reach a constant velocity only at very high energy
 -> we need different types of resonators, optimized for different velocities
 -> the **revolution frequency will vary**, so the RF frequency will be changing
Particle rest mass:
electron   0.511 MeV
proton   938 MeV
^{239}U ~220000 MeV

Relativistic gamma factor:
$$\gamma = \frac{E}{E_0} = \frac{m}{m_0}$$

$$E = E_0 + W$$

$$\beta = \frac{v}{c} = \sqrt{1 - \frac{1}{\gamma^2}}$$

particle kinetic energy W [MeV]

legend: electrons, protons, Uranium

Velocity, Energy and Momentum

normalized velocity $$\beta = \frac{v}{c} = \sqrt{1 - \frac{1}{\gamma^2}}$$

=> electrons almost reach the speed of light very quickly (few MeV range)
$$\frac{\text{total energy}}{\text{rest energy}} \qquad E = \gamma m_0 c^2$$

$$\gamma = \frac{E}{E_0} = \frac{m}{m_0} = \frac{1}{\sqrt{1 - v^2/c^2}} = \frac{1}{\sqrt{1 - \beta^2}}$$

Momentum $$p = mv = \frac{E}{c^2}\beta c = \beta \frac{E}{c} = \beta \gamma m_0 c$$

normalized velocity — electrons, protons, Beta vs E_kinetic (MeV)

total energy / rest energy — electrons, protons, Gamma vs E_kinetic (MeV)

Acceleration + Energy Gain

May the force be with you!

To accelerate, we need a **force in** the **direction of motion**!

Newton-Lorentz Force on a charged particle:

$$\vec{F} = \frac{d\vec{p}}{dt} = e\left(\vec{E} + \vec{v} \times \vec{B}\right)$$

2nd term always perpendicular to motion => no acceleration

Hence, it is necessary to have an *electric field E* (preferably) along the direction of the initial momentum (z), which changes the momentum p of the particle.

$$\frac{dp}{dt} = eE_z$$

In relativistic dynamics, total *energy E* and *momentum p* are linked by

$$E^2 = E_0^2 + p^2 c^2 \implies dE = v\,dp \quad \left(2E\,dE = 2c^2 p\,dp \Leftrightarrow dE = c^2 mv / E\; dp = v\,dp\right)$$

The rate of *energy gain per unit length* of acceleration (along z) is then:
$$\frac{dE}{dz} = v\frac{dp}{dz} = \frac{dp}{dt} = eE_z$$

and the kinetic *energy gained* from the field along the z path is:

$$dW = dE = qE_z\,dz \quad \longrightarrow \quad W = q\int E_z\,dz = qV$$

- V is a potential
- q the charge

Electrostatic Acceleration

**Electrostatic Field:**

Force: $\vec{F} = \frac{d\vec{p}}{dt} = q\,\vec{E}$

Energy gain: W = q ΔV

used for first stage of acceleration: particle sources, electron guns, x-ray tubes

Limitation: insulation problems
   maximum high voltage (~ 10 MV)

Van-de-Graaf generator at MIT

Methods of Acceleration: Time varying fields

The electrostatic field is limited by insulation,
the magnetic field does not accelerate.

From Maxwell's Equations:

$$\vec{E} = -\vec{\nabla}\phi - \frac{\partial \vec{A}}{\partial t}$$

$$\vec{B} = \mu\vec{H} = \vec{\nabla} \times \vec{A} \qquad \text{or} \qquad \nabla \times \vec{E} = -\frac{\partial \vec{B}}{\partial t}$$

The electric field is derived from a scalar potential φ and a vector potential A
The time variation of the magnetic field H generates an electric field E

The **solution**: => **time varying electric fields !**

1) Induction
2) RF frequency fields

Consequence: We can only accelerate bunched beam!

Acceleration by Induction: The Betatron

It is based on the principle of a transformer:
- primary side: large electromagnet   - secondary side: electron beam.
The ramping magnetic field is used to guide particles on a circular trajectory
as well as for acceleration.

Limited by saturation in iron (~300 MeV e-)

Used in industry and medicine, as they are
compact accelerators for electrons

Donald Kerst with the first betatron, invented
at the University of Illinois in 1940
Radio-Frequency (RF) Acceleration

Electrostatic acceleration limited by isolation possibilities => use RF fields

Widerøe-type structure

Cylindrical electrodes (drift tubes) separated by gaps and fed by a RF generator, as shown above, lead to an alternating electric field polarity

Synchronism condition ⟶ $L = v\,T/2$ v = **particle velocity**
T = **RF period**

Similar for standing wave cavity as shown (with $v \approx c$)

D.Schulte

Resonant RF Cavities

- Considering RF acceleration, it is obvious that when particles get high velocities the drift spaces get longer and one looses on the efficiency.
  => The solution consists of using a higher operating frequency.

- The power lost by radiation, due to circulating currents on the electrodes, is proportional to the RF frequency.
  => The solution consists of enclosing the system in a cavity which resonant frequency matches the RF generator frequency.

- The electromagnetic power is now constrained in the resonant volume

- Each such cavity can be independently powered from the RF generator

- Note however that joule losses will occur in the cavity walls (unless made of superconducting materials)

The Pill Box Cavity

$$\longrightarrow E_z \quad \text{-----}\longrightarrow H_\theta$$

From Maxwell's equations one can derive the **wave equations**:

$$\nabla^2 A - \varepsilon_0 \mu_0 \frac{\partial^2 A}{\partial t^2} = 0 \qquad (A = E \text{ or } H)$$

Solutions for E and H are **oscillating modes**, at **discrete frequencies**, of types TM_{xyz} (transverse magnetic) or TE_{xyz} (transverse electric).

Indices linked to the **number of field knots** in polar co-ordinates φ, r and z.

For l<2a the most simple mode, TM_{010}, has the lowest frequency, and has only two field components:
$$E_z = J_0(kr)\, e^{i\omega t}$$

$$H_\theta = -\frac{i}{Z_0} J_1(kr)\, e^{i\omega t}$$

$$k = \frac{2\pi}{\lambda} = \frac{\omega}{c} \quad \lambda = 2.62a \quad Z_0 = 377\Omega$$

The Pill Box Cavity

One needs a hole for the beam pipe – circular waveguide below cutoff

TM_{010}-mode
(only 1/4 shown)

electric field   magnetic field

Transit time factor

The accelerating field varies during the passage of the particle
=> particle does not always see maximum field => effective acceleration smaller

Transit time factor defined as:
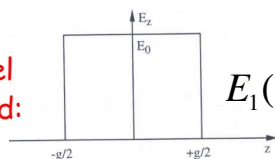

$$T_a = \frac{\text{energy gain of particle with } v = \beta c}{\text{maximum energy gain (particle with } v \to \infty)}$$

In the general case, the transit time factor is:

for $E(s,r,t) = E_1(s,r) \cdot E_2(t)$

$$T_a = \frac{\left| \int\limits_{-\infty}^{+\infty} E_1(s,r) \cos\left(\omega_{RF} \frac{s}{v} \right) \mathrm{d}s \right|}{\int\limits_{-\infty}^{+\infty} E_1(s,r) \, \mathrm{d}s}$$
Simple model uniform field:

$$E_1(s,r) = \frac{V_{RF}}{g}$$

follows:

$$T_a = \left| \sin \frac{\omega_{RF} g}{2v} \middle/ \frac{\omega_{RF} g}{2v} \right|$$

$0 < T_a < 1$, $T_a \to 1$ for $g \to 0$, smaller ω_{RF}
Important for low velocities (ions)

Field rotates by 360° during particle passage.

$$\frac{\omega_{RF} g}{2\pi v}$$

The Pill Box Cavity (2)

The design of a cavity can be sophisticated in order to improve its performances:

- A nose cone can be introduced in order to concentrate the electric field around the axis

- Round shaping of the corners allows a better distribution of the magnetic field on the surface and a reduction of the Joule losses.
It also prevents from multipactoring effects (e- emission and acceleration).

A good cavity efficiently transforms the RF power into accelerating voltage.
Simulation codes allow precise calculation of the properties.

Multi-Cell Cavities

Acceleration of one cavity limited => distribute power over several cells
Each cavity receives P/n
Since the field is proportional √P, you get

$$\sum E_i \propto n\sqrt{P/n} = \sqrt{n}E_0$$

Instead of distributing the power from the amplifier, one might as well
couple the cavities, such that the power automatically distributes, or have
a cavity with many gaps (e.g. drift tube linac).

ACCELERATING CAVITY

COUPLING CAVITY
Multi-Cell Cavities - Modes

The phase relation between
gaps is important!

Coupled harmonic oscillator

=> Modes, named after the
phase difference between
adjacent cells.

Relates to different
synchronism conditions for
the cell length L

Mode	L
0 (2π)	βλ
π/2	βλ/4
2π/3	βλ/3
π	βλ/2

π

2π/3

0
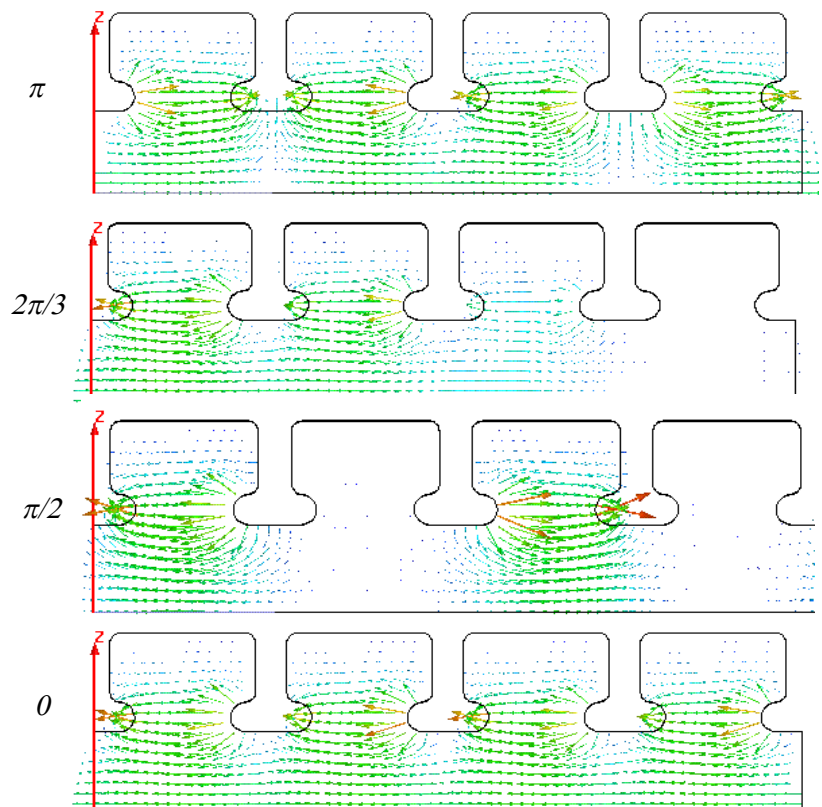

Disc-Loaded Traveling-Wave Structures

When particles gets ultra-relativistic (v~c) the drift tubes become very long unless the operating frequency is increased. Late 40's the development of radar led to high power transmitters (klystrons) at very high frequencies (3 GHz).

Next came the idea of suppressing the drift tubes using traveling waves. However to get a continuous acceleration the phase velocity of the wave needs to be adjusted to the particle velocity.
solution: slow wave guide with irises   ==>   iris loaded structure

The Traveling Wave Case

$$E_z = E_0 \cos\left(\omega_{RF} t - kz\right)$$

$$k = \frac{\omega_{RF}}{v_\varphi} \qquad \text{wave number}$$

$$z = v(t - t_0)$$

v_φ = phase velocity
v = particle velocity

The particle travels along with the wave, and k represents the wave propagation factor.

$$E_z = E_0 \cos\left(\omega_{RF} t - \omega_{RF} \frac{v}{v_\varphi} t - \phi_0\right)$$

If synchronism satisfied: $v = v_\varphi$ and $E_z = E_0 \cos\phi_0$
where Φ_0 is the RF phase seen by the particle.

Cavity Parameters: Quality Factor Q

The total energy stored is
$$W = \iiint_{cavity} \left(\frac{\varepsilon}{2}|\vec{E}|^2 + \frac{\mu}{2}|\vec{H}|^2 \right) dV.$$

- Quality Factor Q (caused by wall losses) defined as

$$Q_0 = \frac{\omega_0 W}{P_{loss}}$$

Ratio of stored energy W and dissipated power P_{loss} on the walls in one RF cycle

The Q factor determines the maximum energy the cavity can fill to with a given input power.
Larger Q => less power needed to sustain stored energy.

The Q factor is 2π times the number of rf cycles it takes to dissipate the energy stored in the cavity (down by 1/e).

- function of the geometry and the surface resistance of the material:
    superconducting (niobium) : Q= 10^{10}
    normal conducting (copper) : Q=10^4

Important Parameters of Accelerating Cavities

- Accelerating voltage V_{acc}

$$V_{acc} = \int_{-\infty}^{\infty} E_z e^{-i\frac{\omega z}{\beta c}} dz$$

Measure of the acceleration

- R upon Q

$$\frac{R}{Q} = \frac{|V_{acc}|^2}{2\omega_0 W}$$

Relationship between acceleration V_{acc} and stored energy W

independent from material!

Attention: Different definitions are used!

- Shunt Impedance R

$$R = \frac{|V_{acc}|^2}{2P_{loss}}$$

Relationship between acceleration V_{acc} and wall losses P_{loss}

depends on
- material
- cavity mode
- geometry

Important Parameters of Accelerating Cavities (cont.)

- Fill Time t_F

  - **standing wave cavities:**

$$P_{loss} = -\frac{dW}{dt} = \frac{\omega}{Q}W$$

Exponential decay of the stored energy W due to losses

$$t_F = \frac{Q}{\omega}$$

time for the field to decrease by 1/e after the cavity has been filled
measure of how fast the stored energy is dissipated on the wall

Several fill times needed to fill the cavity!

  - **travelling wave cavities:**
  time needed for the electromagnetic energy to fill the cavity of length L

$$t_F = \int_0^L \frac{dz}{v_g(z)}$$

v_g: velocity at which the energy propagates through the cavity

Cavity is completely filled after 1 fill time!

Common Phase Conventions

1. For circular accelerators, the origin of time is taken at the zero crossing of the RF voltage with positive slope

2. For linear accelerators, the origin of time is taken at the positive crest of the RF voltage

Time t= 0 chosen such that:

$$E_1(t) = E_0 \sin(\omega_{RF} t)$$

$$E_2(t) = E_0 \cos(\omega_{RF} t)$$
3.   I will stick to **convention 1** in the following to avoid confusion

Principle of Phase Stability (Linac)

Let's consider a succession of accelerating gaps, operating in the 2π mode, for which the synchronism condition is fulfilled for a phase Φs .

$$eV_S = e\hat{V}\sin\Phi_S$$

is the energy gain in one gap for the particle to reach the next gap with the same RF phase: P_1 , P_2, …… are fixed points.
For a 2π mode, the electric field is the same in all gaps at any given time.
If an energy increase is transferred into a velocity increase =>
M_1 & N_1 will move towards P_1 => stable
M_2 & N_2 will go away from P_2 => unstable
(Highly relativistic particles have no significant velocity change)

A Consequence of Phase Stability

The divergence of the field is zero according to Maxwell :

$$\nabla\vec{E} = 0 \quad\Rightarrow\quad \frac{\partial E_x}{\partial x} + \frac{\partial E_z}{\partial z} = 0 \quad\Rightarrow\quad \frac{\partial E_x}{\partial x} = -\frac{\partial E_z}{\partial z}$$

Transverse fields
* focusing at the entrance and
* defocusing at the exit of the cavity.

Electrostatic case: Energy gain inside the cavity leads to focusing
RF case: Field increases during passage => transverse defocusing!

External focusing (solenoid, quadrupole) is then necessary

Energy-phase Oscillations (Small Amplitude) (1)

- Rate of energy gain for the synchronous particle:

$$\frac{dE_s}{dz} = \frac{dp_s}{dt} = eE_0 \sin\phi_s$$

- Rate of energy gain for a non-synchronous particle, expressed in **reduced variables**, $w = W - W_s = E - E_s$ and $\varphi = \phi - \phi_s$:

$$\frac{dw}{dz} = eE_0[\sin(\phi_s + \varphi) - \sin\phi_s] \approx eE_0 \cos\phi_s . \varphi \quad (small\ \varphi)$$

- Rate of change of the phase with respect to the synchronous one:

$$\frac{d\varphi}{dz} = \omega_{RF}\left(\frac{dt}{dz} - \left(\frac{dt}{dz}\right)_s\right) = \omega_{RF}\left(\frac{1}{v} - \frac{1}{v_s}\right) \cong -\frac{\omega_{RF}}{v_s^2}(v - v_s)$$

Leads finally to:
$$\frac{d\varphi}{dz} = -\frac{\omega_{RF}}{m_0 v_s^3 \gamma_s^3} w$$

Energy-phase Oscillations (Small Amplitude) (2)

Combining the two 1st order equations into a 2nd order equation gives the equation of a harmonic oscillator:

$$\frac{d^2\varphi}{dz^2} + \Omega_s^2 \varphi = 0 \qquad \text{with} \qquad \Omega_s^2 = \frac{eE_0\omega_{RF}\cos\phi_s}{m_0 v_s^3 \gamma_s^3}$$

Slower for higher energy!
Stable harmonic oscillations imply: $\Omega_s^2 > 0$ and real

hence: $\cos\phi_s > 0$
And since acceleration also means:

$$\sin\phi_s > 0$$

You finally get the result for the stable phase range:

$$0 < \phi_s < \frac{\pi}{2}$$

Longitudinal phase space

The energy – phase oscillations can be drawn in phase space:

The particle trajectory in the phase space ($\Delta p/p$, ϕ) describes its longitudinal motion.

Emittance: phase space area including all the particles

NB: if the emittance contour correspond to a possible orbit in phase space, its shape does not change with time (matched beam)

Longitudinal Dynamics - Electrons

At relativistic velocity phase oscillations stop – the bunch is frozen longitudinally.
=> Acceleration can be at the crest of the RF for maximum energy gain.

Electrons injected into a TW structure designed for v=c:

$$\cos\phi = \cos\phi_0 + \frac{2\pi}{\lambda_g}\frac{mc^2}{qE_0}\left[\sqrt{\frac{1-\beta}{1+\beta}} - \sqrt{\frac{1-\beta_0}{1+\beta_0}}\right]$$

→ at v=c remain at the injection phase.

→ at v<c will move from injection phase φ_0 to an asymptotic phase φ, which depends on gradient E_0 and β_0 at injection.
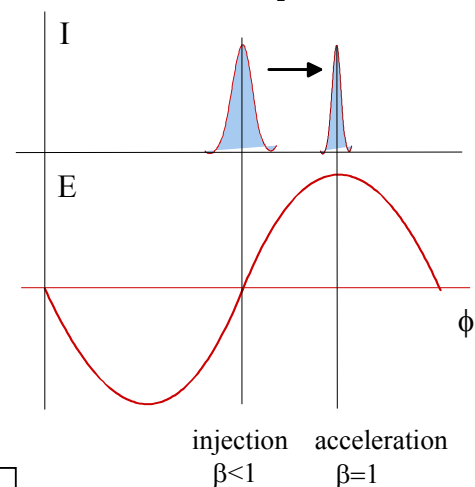

The beam can be injected with an offset in phase, to reach the crest of the wave at $\beta=1$

Capture condition, relating gradient E_0 and β_0:

$$E_0 \geq \frac{2\pi}{\lambda_g}\frac{mc^2}{q}\left[\sqrt{\frac{1-\beta_0}{1+\beta_0}}\right]$$

injection β<1   acceleration β=1

Example: λ=10cm → W_{in}=150 keV for E_0=8 MV/m.

In high current linacs, a bunching and pre-acceleration sections up to 4-10 MeV prepares the injection in the TW structure (that occurs already on the crest)

Bunching with a Pre-buncher

A long bunch coming from the gun enters an RF cavity.
The reference particle is the one which has no velocity change. The others get accelerated or decelerated, so the bunch gets an energy and velocity modulation.

After a distance L bunch gets shorter: bunching effect.
This short bunch can now be captured more efficiently by a TW structure ($v_\varphi = c$).
Bunch compression

At ultra-relativistic energies ($\gamma \gg 1$) the longitudinal motion is frozen.
For linear e+/e- colliders, you need very short bunches (few 100-50μm).

Solution: introduce **energy/time correlation** + a magnetic **chicane**.

Increases energy spread in the bunch => chromatic effects
=> compress at low energy before further acceleration to reduce relative $\Delta E/E$
long.
phase
space

N.Walker

Longitudinal Wake Fields - Beamloading

Beam induces wake fields in cavities (in general when chamber profile changing)
⇒ decreasing RF field in cavities
(beam absorbs RF power when accelerated)

Particles within a bunch see a decreasing field
⇒ energy gain different within the single bunch
Locating bunch off-crest
at the best RF phase
minimises energy spread

wakefield

RF

$\varphi = 15.5°$

Total

Example: Energy gain
along the bunch
in the NLC linac (TW):
The Radio-Frequency Quadrupole - RFQ

Initial acceleration difficult for protons and ions at low energy
(space charge, low β ⇒ short cell dimensions, bunching needed)

RFQ = Electric quadrupole
        focusing channel + bunching + acceleration

Alternating electric quadrupole field gives
transverse focusing like magnetic focusing channel.
Does not depend on velocity!
Ideal at low β!

The Radio-Frequency Quadrupole - RFQ

The vanes have a <u>longitudinal modulation</u> with period = $\beta\lambda$

$\rightarrow$ this creates a longitudinal component of the electric field.

The modulation corresponds exactly to a series of RF gaps and can provide acceleration.

Modulated vane — Opposite vanes (180°)

Modulated vane — Adjacent vanes (90°)

RF Field excitation:

An empty cylindrical cavity can be excited on different modes.

Some of these modes have only transverse electric field (the TE modes), and one uses in particular the "quadrupole" mode, the TE_{210}.

Empty cavity; mode TE_{21}

Cavity with vanes
RFQ Design + Longitudinal Phase Space

RFQ design: The <u>modulation period</u> can be slightly adjusted to change the phase of the beam inside the RFQ cells, and the <u>amplitude of the modulation</u> can be changed to change the accelerating gradient
$\rightarrow$ start with some bunching cells, progressively bunch the beam (<u>adiabatic bunching channel</u>), and only in the last cells accelerate.
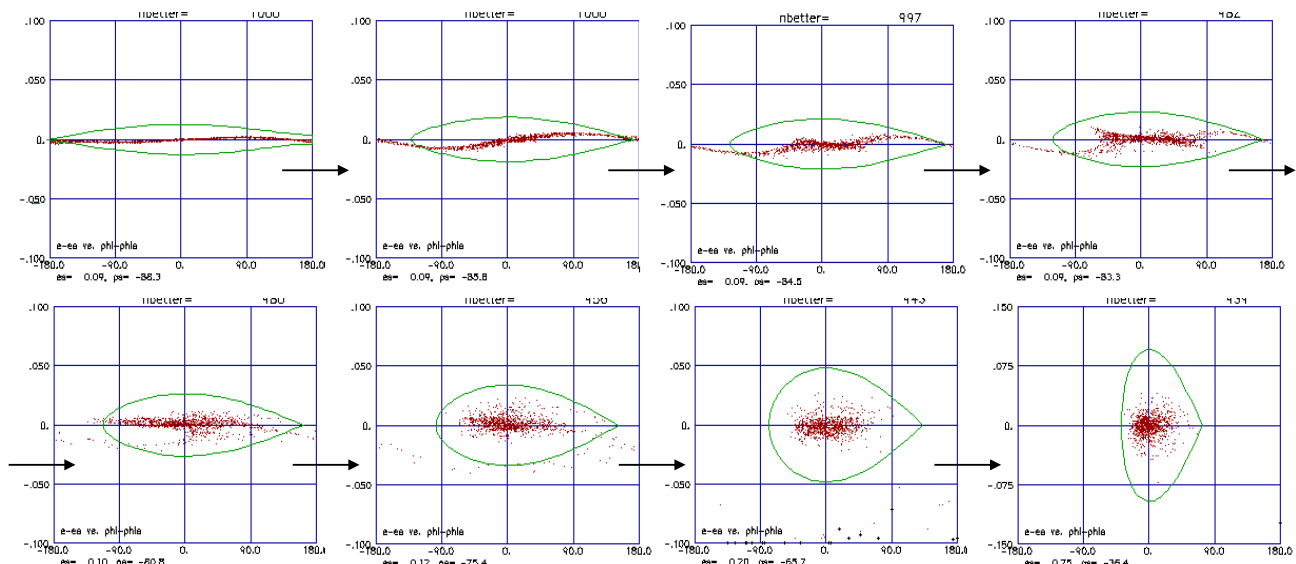

Longitudinal beam profile of a proton beam along the CERN RFQ2

Summary up to here…

- **Acceleration by electric fields**, static fields limited
  => time-varying fields

- **Synchronous condition** needs to be fulfilled for acceleration

- Particles perform **oscillation** around synchronous phase

- visualize oscillations in phase space

- Electrons are quickly relativistic, speed does not change
  use traveling wave structures for acceleration

- Protons and ions

  - RFQ for bunching and first acceleration

  - need changing structure geometry

Summary: Relativity + Energy Gain

Newton-Lorentz Force $\vec{F} = \dfrac{\mathrm{d}\vec{p}}{\mathrm{d}t} = e\left(\vec{E} + \vec{v} \times \vec{B}\right)$ 2nd term always perpendicular to motion => no acceleration

Relativistics Dynamics

$$\beta = \frac{v}{c} = \sqrt{1 - \frac{1}{\gamma^2}} \qquad \gamma = \frac{E}{E_0} = \frac{m}{m_0} = \frac{1}{\sqrt{1 - \beta^2}}$$

$$p = mv = \frac{E}{c^2}\beta c = \beta\frac{E}{c} = \beta\gamma\, m_0 c$$

$$E^2 = E_0^2 + p^2 c^2 \qquad\longrightarrow\qquad dE = v\,dp$$

$$\frac{dE}{dz} = v\frac{dp}{dz} = \frac{dp}{dt} = eE_z$$

$$dE = dW = eE_z\,dz \quad\rightarrow\quad W = e\int E_z\,dz$$

RF Acceleration

$$E_z = \hat{E}_z \sin\omega_{RF}t = \hat{E}_z \sin\phi(t)$$

$$\int \hat{E}_z\,dz = \hat{V}$$

$$W = e\hat{V}\sin\phi$$

(neglecting transit time factor)

The field will change during the passage of the particle through the cavity
=> effective energy gain is lower

Examples of different proton and electron synchrotrons at CERN

+ LHC (of course!)

The Synchrotron

The synchrotron is a synchronous accelerator since there is a synchronous RF phase for which the energy gain fits the increase of the magnetic field at each turn. That implies the following operating conditions:
$e\hat{V}\sin\phi$ ⟶ **Energy gain per turn**

$\phi = \phi_s = cte$ ⟶ **Synchronous particle**

$\omega_{RF} = h\omega$ ⟶ **RF synchronism (h - harmonic number)**

$\rho = cte \quad R = cte$ → **Constant orbit**

$B\rho = P/e \Rightarrow B$ ⟶ **Variable magnetic field**

If v≈c, ω hence ω$_{RF}$ remain constant (ultra-relativistic e⁻)

The Synchrotron – LHC Operation Cycle

dipole current (A)

time from start of injection (s)
L.Bottura

The Synchrotron – Energy ramping

Energy ramping by increasing the B field (frequency has to follow v):

$$p = eB\rho \quad \Rightarrow \quad \frac{dp}{dt} = e\rho\,\dot{B} \quad \Rightarrow (\Delta p)_{turn} = e\rho\,\dot{B}T_r = \frac{2\pi\,e\rho\,R\dot{B}}{v}$$

Since:

$$E^2 = E_0^2 + p^2c^2 \quad \Rightarrow \quad \Delta E = v\Delta p$$

$$\left(\Delta E\right)_{turn} = \left(\Delta W\right)_s = 2\pi e\rho R\dot{B} = e\hat{V}\sin\phi_s$$

Stable phase φ_s changes during energy ramping

$$\sin\phi_s = 2\pi\rho R\,\frac{\dot{B}}{\hat{V}_{RF}} \quad \Longrightarrow \quad \phi_s = \arcsin\left(2\pi\rho R\,\frac{\dot{B}}{\hat{V}_{RF}}\right)$$

- The number of stable synchronous particles is equal to the harmonic number h. They are equally spaced along the circumference.
- Each synchronous particle satisfies the relation p=eBρ. They have the nominal energy and follow the nominal trajectory.

The Synchrotron – Frequency change

During the energy ramping, the RF frequency increases to follow the increase of the revolution frequency :
$$\omega = \frac{\omega_{RF}}{h} = \omega(B, R_s)$$

Hence: $\dfrac{f_{RF}(t)}{h} = \dfrac{v(t)}{2\pi R_s} = \dfrac{1}{2\pi} \dfrac{ec^2}{E_s(t)} \dfrac{\rho}{R_s} B(t)$ (using $p(t) = eB(t)\rho$, $E = mc^2$)

Since $E^2 = (m_0 c^2)^2 + p^2 c^2$ the RF frequency must follow the variation of the B field with the law

$$\frac{f_{RF}(t)}{h} = \frac{c}{2\pi R_s} \left\{ \frac{B(t)^2}{(m_0 c^2 / ec\rho)^2 + B(t)^2} \right\}^{1/2}$$

This asymptotically tends towards compared to $m_0 c^2 / (ec\rho)$ which corresponds to $v \longrightarrow c$ $f_r \longrightarrow \dfrac{c}{2\pi R_s}$ when B becomes large

Dispersion Effects in a Synchrotron

cavity

Circumference
2πR

E

← E+δE

p=particle momentum

R=synchrotron physical radius

f_r=revolution frequency

A particle with a momentum deviation will have a

- dispersion orbit and a different orbit length
- a different velocity.

As a result of both effects the revolution frequency changes with a "slip factor η":

$$\eta = \frac{df_r / f_r}{dp / p} \implies$$

Note: you also find η defined with a minus sign!

Effect from orbit defined by Momentum compaction factor: $\alpha_c = \dfrac{dL/L}{dp/p}$

Property of the beam optics:
(derivation next page)

$$\alpha_c = \frac{1}{L} \int_C \frac{D_x(s)}{\rho(s)} ds_0$$

Derivation: Momentum Compaction Factor

$$\alpha_c = \frac{p}{L}\frac{dL}{dp}$$

$$ds_0 = \rho\, d\theta$$
$$ds = (\rho + x)\, d\theta$$

The elementary path difference from the two orbits is:

definition of dispersion D_x

$$\frac{dl}{ds_0} = \frac{ds - ds_0}{ds_0} = \frac{x}{\rho} = \frac{D_x}{\rho}\frac{dp}{p}$$

leading to the total change in the circumference:

$$dL = \int_C dl = \int \frac{x}{\rho}\, ds_0 = \int \frac{D_x}{\rho}\frac{dp}{p}\, ds_0$$

$$\alpha_c = \frac{1}{L}\int_C \frac{D_x(s)}{\rho(s)}\, ds_0$$

With $\rho = \infty$ in straight sections we get:

$$\alpha_c = \frac{\langle D_x \rangle_m}{R}$$

< >$_m$ means that the average is considered over the bending magnet only

Dispersion Effects – Revolution Frequency

The two effects of the orbit length and the particle velocity change the revolution frequency as:

$$f_r = \frac{\beta c}{2\pi R} \quad\Rightarrow\quad \frac{df_r}{f_r} = \frac{d\beta}{\beta} - \frac{dR}{R} = \frac{d\beta}{\beta} - \alpha_c\frac{dp}{p}$$

definition of momentum compaction factor

$$\frac{df_r}{f_r} = \left(\frac{1}{\gamma^2} - \alpha_c\right)\frac{dp}{p}$$

$$p = mv = \beta\gamma\frac{E_0}{c} \Rightarrow \frac{dp}{p} = \frac{d\beta}{\beta} + \frac{d\left(1-\beta^2\right)^{-\frac{1}{2}}}{\left(1-\beta^2\right)^{-\frac{1}{2}}} = \underbrace{\left(1-\beta^2\right)^{-1}}_{\gamma^2}\frac{d\beta}{\beta}$$

Slip factor:
$$\eta = \frac{1}{\gamma^2} - \alpha_c \qquad \text{or} \qquad \eta = \frac{1}{\gamma^2} - \frac{1}{\gamma_t^2} \qquad \text{with} \qquad \gamma_t = \frac{1}{\sqrt{\alpha_c}}$$

At transition energy, $\eta = 0$, the velocity change and the path length change with momentum compensate each other. So the revolution frequency there is independent from the momentum deviation.

Phase Stability in a Synchrotron

From the definition of η it is clear that an increase in momentum gives
- below transition (η > 0) a higher revolution frequency
  (increase in velocity dominates) while
- above transition (η < 0) a lower revolution frequency (v ≈ c and longer path)
  where the momentum compaction (generally > 0) dominates.

$$\eta = \frac{1}{\gamma^2} - \alpha_c$$

Crossing Transition

At transition, the velocity change and the path length change with momentum compensate each other. So the revolution frequency there is independent from the momentum deviation.

Crossing transition during acceleration makes the previous stable synchronous phase unstable. The RF system needs to make a rapid change of the RF phase, a 'phase jump'.

$$\alpha_c \sim \frac{1}{Q_x^2} \qquad \gamma_t = \frac{1}{\sqrt{\alpha_c}} \sim Q_x$$
In the PS: γ_t is at ~6 GeV
In the SPS: γ_t= 22.8, injection at γ=27.7
         => no transition crossing!
In the LHC: γ_t is at ~55 GeV, also far below injection energy

Transition crossing not needed in leptons machines, why?

Dynamics: Synchrotron oscillations

Simple case (no accel.): B = const., below transition $\qquad \gamma < \gamma_{tr}$

The phase of the synchronous particle must therefore be $\phi_0 = 0$.

ϕ_1 - The particle B is accelerated
           - Below transition, an increase in energy means an increase in revolution frequency
   - The particle arrives earlier – tends toward ϕ_0
ϕ_2 - The particle is decelerated
           - decrease in energy - decrease in revolution frequency
   - The particle arrives later – tends toward ϕ_0

Longitudinal Phase Space Motion

Particle B performs a synchrotron oscillation around the synchronous particle A

Plotting this motion in longitudinal phase space gives:

Synchrotron oscillations – No acceleration

Phase space picture
Synchrotron motion in phase space

Remark:
Synchrotron frequency
much smaller than
betatron frequency.

The restoring force is
non-linear.
$\Rightarrow$ speed of motion
depends on position in
phase-space

(here shown for a
stationary bucket)
Synchrotron motion in phase space

The symmetry of the
case B = const. is lost

RF Acceptance versus Synchronous Phase

The areas of stable motion (closed trajectories) are called "BUCKET". The number of circulating buckets is equal to "h".

The phase extension of the bucket is maximum for ϕ_s =180° (or 0°) which means no acceleration.

During acceleration, the buckets get smaller, both in length and energy acceptance.
=> Injection preferably without acceleration.

Longitudinal Motion with Synchrotron Radiation

Synchrotron radiation energy-loss energy dependant:

$$U_0 = \frac{4}{3}\pi \frac{r_e}{\left(m_0 c^2\right)^3} \frac{E^4}{\rho}$$

During one period of synchrotron oscillation:

- when the particle is in the upper half-plane, it loses more energy per turn, its energy gradually reduces

- when the particle is in the lower half-plane, it loses less energy per turn, but receives U_0 on the average, so its energy deviation gradually reduces

The phase space trajectory spirals towards the origin (limited by quantum excitations)

=> The synchrotron motion is damped toward an equilibrium bunch length and energy spread.

More details in *Andy Wolski's* lectures on *'Low Emittance Machines'*

$$\sigma_\tau = \frac{\alpha}{\Omega_s}\left(\frac{\sigma_\varepsilon}{E}\right)$$

Longitudinal Dynamics in Synchrotrons

Now we will look more quantitatively at the "synchrotron motion".

The RF acceleration process clearly emphasizes two coupled variables, the energy gained by the particle and the RF phase experienced by the same particle.

Since there is a well defined synchronous particle which has always the same phase ϕ_s, and the nominal energy E_s, it is sufficient to follow other particles with respect to that particle.

So let's introduce the following reduced variables:

revolution frequency : $\quad \Delta f_r = f_r - f_{rs}$

particle RF phase : $\quad \Delta\phi = \phi - \phi_s$

particle momentum : $\quad \Delta p = p - p_s$

particle energy : $\quad \Delta E = E - E_s$

azimuth angle : $\quad \Delta\theta = \theta - \theta_s$

Equations of Longitudinal Motion

In these reduced variables, the equations of motion are (see Appendix):

$$\frac{\Delta E}{\omega_{rs}} = -\frac{p_s R_s}{h\eta\omega_{rs}}\frac{d(\Delta\phi)}{dt} = -\frac{p_s R_s}{h\eta\omega_{rs}}\dot{\phi}$$

$$2\pi\frac{d}{dt}\left(\frac{\Delta E}{\omega_{rs}}\right) = e\hat{V}(\sin\phi - \sin\phi_s)$$

deriving and combining

$$\frac{d}{dt}\left[\frac{R_s p_s}{h\eta\omega_{rs}}\frac{d\phi}{dt}\right] + \frac{e\hat{V}}{2\pi}(\sin\phi - \sin\phi_s) = 0$$

This second order equation is non linear. Moreover the parameters within the bracket are in general slowly varying with time.

We will simplify in the following…

Small Amplitude Oscillations

Let's assume constant parameters R_s, p_s, ω_s and η:

$$\ddot{\phi} + \frac{\Omega_s^2}{\cos\phi_s}(\sin\phi - \sin\phi_s) = 0 \qquad \text{with} \qquad \Omega_s^2 = \frac{h\eta\omega_{rs}e\hat{V}\cos\phi_s}{2\pi R_s p_s}$$

Consider now small phase deviations from the reference particle:

$$\sin\phi - \sin\phi_s = \sin(\phi_s + \Delta\phi) - \sin\phi_s \cong \cos\phi_s\Delta\phi \qquad \text{(for small } \Delta\phi\text{)}$$

and the corresponding linearized motion reduces to a harmonic oscillation:

$$\ddot{\phi} + \Omega_s^2\Delta\phi = 0$$
where Ω_s is the synchrotron angular frequency.

The **synchrotron tune** ν_s is the number of synchrotron oscillations per revolution:

$$\nu_s = \Omega_s/\omega_r$$

Stability condition for φ_s

Stability is obtained when Ω_s is real and so Ω_s^2 positive:

$$\Omega_s^2 = \frac{e\hat{V}_{RF}\eta h\omega_s}{2\pi R_s p_s}\cos\phi_s \quad \Rightarrow \quad \Omega_s^2 > 0 \quad \Leftrightarrow \quad \boxed{\eta\cos\phi_s > 0}$$

Stable in the region if

	$\gamma < \gamma_{tr}$	$\gamma > \gamma_{tr}$	$\gamma > \gamma_{tr}$	$\gamma < \gamma_{tr}$
	$\eta > 0$	$\eta < 0$	$\eta < 0$	$\eta > 0$

acceleration   deceleration

Large Amplitude Oscillations

For larger phase (or energy) deviations from the reference the second order differential equation is non-linear:

$$\ddot{\phi} + \frac{\Omega_s^2}{\cos\phi_s}\left(\sin\phi - \sin\phi_s\right) = 0 \qquad (\Omega_s \text{ as previously defined})$$

Multiplying by $\dot{\phi}$ and integrating gives an invariant of the motion:

$$\frac{\dot{\phi}^2}{2} - \frac{\Omega_s^2}{\cos\phi_s}\left(\cos\phi + \phi\sin\phi_s\right) = I$$

which for small amplitudes reduces to:

$$\frac{\dot{\phi}^2}{2} + \Omega_s^2\frac{(\Delta\phi)^2}{2} = I' \qquad \text{(the variable is } \Delta\phi\text{, and } \phi_s \text{ is constant)}$$

Similar equations exist for the second variable : $\Delta E \propto d\phi/dt$

Large Amplitude Oscillations (2)

When ϕ reaches $\pi-\phi_s$ the force goes to zero and beyond it becomes non restoring.
Hence $\pi-\phi_s$ is an extreme amplitude for a stable motion which in the phase space($\dfrac{\dot{\phi}}{\Omega_s}, \Delta\phi$) is shown as closed trajectories.

Equation of the separatrix:

$$\frac{\dot{\phi}^2}{2} - \frac{\Omega_s^2}{\cos\phi_s}\left(\cos\phi + \phi\sin\phi_s\right) = -\frac{\Omega_s^2}{\cos\phi_s}\left(\cos(\pi-\phi_s) + (\pi-\phi_s)\sin\phi_s\right)$$

Second value ϕ_m where the separatrix crosses the horizontal axis:

$$\cos\phi_m + \phi_m\sin\phi_s = \cos(\pi-\phi_s) + (\pi-\phi_s)\sin\phi_s$$

Energy Acceptance

From the equation of motion it is seen that $\dot{\phi}$ reaches an extreme when $\ddot{\phi}=0$, hence corresponding to $\phi=\phi_s$.

Introducing this value into the equation of the separatrix gives:

$$\dot{\phi}^2_{\max} = 2\Omega_s^2 \left\{ 2 + \left(2\phi_s - \pi \right)\tan\phi_s \right\}$$

That translates into an acceptance in energy:

$$\left(\frac{\Delta E}{E_s} \right)_{\max} = \mp\beta \sqrt{-\frac{e\hat{V}}{\pi h \eta E_s} G(\phi_s)}$$

$$G(\phi_s) = \left[2\cos\phi_s + \left(2\phi_s - \pi \right)\sin\phi_s \right]$$

This "RF acceptance" depends strongly on ϕ_s and plays an important role for the capture at injection, and the stored beam lifetime.

It's largest for $\phi_s = 0$ and $\phi_s = \pi$ (no acceleration, depending on η).

Need a higher RF voltage for higher acceptance.

RF Acceptance versus Synchronous Phase

The areas of stable motion (closed trajectories) are called "BUCKET".

As the synchronous phase gets closer to 90° the buckets gets smaller.

The number of circulating buckets is equal to "h".

The phase extension of the bucket is maximum for ϕ_s =180° (or 0°) which correspond to no acceleration . The RF acceptance increases with the RF voltage.

Bunch-to-bucket transfer

- Bunch from sending accelerator
  into the bucket of receiving
Advantages:

→ Particles always subject to longitudinal focusing

→ No need for RF capture of de-bunched beam in receiving accelerator

→ No particles at unstable fixed point

→ Time structure of beam preserved during transfer

Bunch Transfer - Effect of a Mismatch

When you transfer the bunch from one RF system to another, the shape of the phase space and the bunch need to match.

Mismatch example: Injected bunch: short length and large energy spread after 1/4 synchrotron period: longer bunch with a smaller energy spread.

For larger amplitudes, the angular phase space motion is slower
(1/8 period shown below)   => can lead to filamentation and emittance growth

restoring force is
non-linear

# Effect of a Mismatch (2)

Evolution of an injected beam for the first 100 turns.

For a matched transfer, the emittance does not grow (left).

matched beam   mismatched beam – **bunch length**

Effect of a Mismatch (3)

Evolution of an injected beam for the first 100 turns.

For a mismatched transfer, the emittance increases (right).

matched beam   mismatched beam – **phase error**
Effect of a Mismatch (4)

- Long. emittance is only preserved for correct RF voltage

| Matched case	Longitudinal mismatch

→ Bunch is fine, longitudinal emittance remains constant

→ Dilution of bunch results in increase of long. emittance

Longitudinal matching – Beam profile

Matched case

$\Delta\phi = 0$, $V_{inj}/V_{RF} = 1$

Longitudinal mismatch

$\Delta\phi = 0$, $V_{inj}/V_{RF} = 2$

→ Bunch is fine, longitudinal emittance remains constant
→ Dilution of bunch results in increase of long. emittance

Matching quiz!

- ## Find the difference!

→ -45° phase error at injection

→ Can be easily corrected by bucket phase

→ Equivalent energy error

→ Phase does not help: requires beam energy change

## Phase Space Tomography

We can reconstruct the phase space distribution of the beam.

- Longitudinal bunch profiles over a number of turns

- Parameters determining Ω_s

1st bunch

2nd bunch

Bunch Rotation

Phase space motion can be used to make short bunches.
Start with a long bunch and extract or recapture when it's short.

CAPTURE OF DEBUNCHED BEAM WITH ADIABATIC TURN-ON   TURN   1000
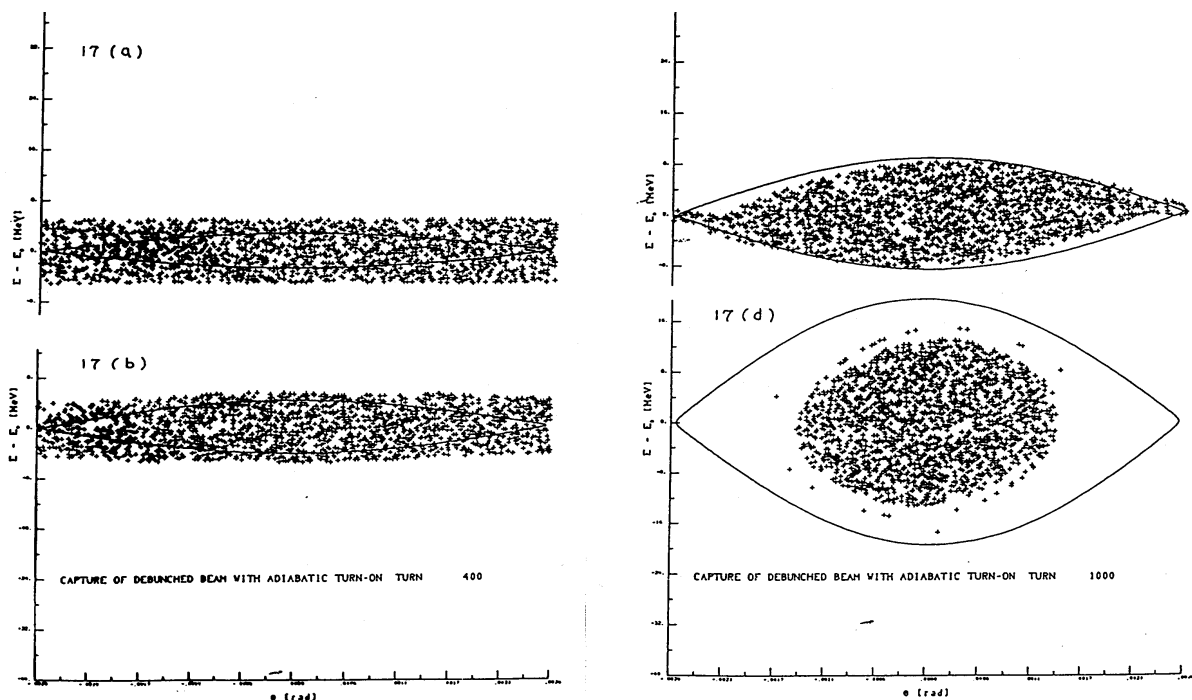

Potential Energy Function

The longitudinal motion is produced by a force that can be derived from a scalar potential:

$$\frac{d^2\phi}{dt^2}=F(\phi) \qquad F(\phi)=-\frac{\partial U}{\partial \phi}$$

$$U=-\int_0^\phi F(\phi)d\phi=-\frac{\Omega_s^2}{\cos\phi_s}\left(\cos\phi+\phi\sin\phi_s\right)-F_0$$

$$\frac{\dot\phi^2}{2}+U(\phi)=F_0$$
The sum of the potential energy and kinetic energy is constant and by analogy represents the total energy of a non-dissipative system.

Hamiltonian of Longitudinal Motion

Introducing a new convenient variable, W, leads to the 1st order equations:

$$W = \frac{\Delta E}{\omega_{rs}}$$

$$\longrightarrow$$

$$\frac{d\phi}{dt} = -\frac{h\eta\omega_{rs}}{pR}W$$

$$\frac{dW}{dt} = \frac{e\hat{V}}{2\pi}(\sin\phi - \sin\phi_s)$$

The two variables ϕ,W are canonical since these equations of motion can be derived from a Hamiltonian H(ϕ,W,t):

$$\frac{d\phi}{dt} = \frac{\partial H}{\partial W} \qquad \frac{dW}{dt} = -\frac{\partial H}{\partial \phi}$$

$$H(\phi, W) = -\frac{1}{2}\frac{h\eta\omega_{rs}}{pR}W^2 + \frac{e\hat{V}}{2\pi}[\cos\phi - \cos\phi_s + (\phi - \phi_s)\sin\phi_s]$$

Hamiltonian of Longitudinal Motion

What does it represent?   The total energy of the system!

Surface of H (φ,W)   Contours of H (φ,W)

Chris Warsop
Contours of constant H are particle trajectories in phase space! (H is conserved)

Hamiltonian Mechanics can help us understand some fairly complicated dynamics (multiple harmonics, bunch splitting, …)

Generating a 25ns LHC Bunch Train in the PS

- ## Longitudinal bunch splitting (basic principle)
  - Reduce voltage on principal RF harmonic and simultaneously rise voltage on multiple harmonics (adiabatically with correct phase, etc.)

PS ejection: 72 bunches in 1 turn

320 ns beam gap

72 bunches on h=84

40 MHz fixed RF = 40.0 MHz 1.1×10^{11} ppb & 20 MHz fixed RF = 20.0 MHz 2.2×10^{11} ppb

Quadruple splitting at 25 GeV

Acceleration to 25 GeV

18 bunches on h=21

10 MHz system RF = 9.18 MHz 4.4×10^{11} ppb

Triple splitting at 1.4 GeV

PS injection: 4+2 bunches in 2 batches

Empty bucket

6 bunches on h=7

10 MHz system RF = 3.06 MHz 13.2×10^{11} ppb

R. Garoby

**Use double splitting at 25 GeV to generate 50ns bunch trains instead**

Production of the LHC 25 ns beam

**1. Inject four bunches**   **~ 180 ns, 1.3 eVs**
Wait 1.2 s for second injection

2. Inject two bunches

3. Triple split after second injection

~ 0.7 eVs

4. Accelerate from 1.4 GeV (E_{kin}) to 26 GeV

Production of the LHC 25 ns beam

5. During acceleration: longitudinal emittance blow-up: 0.7 – 1.3 eVs
6. Double split ($h21 \rightarrow h42$)
7. Double split ($h42 \rightarrow h84$)   ~ 0.35 eVs, 4 ns
10. Fine synchronization, bunch rotation → Extraction!

The LHC25 (ns) cycle in the PS

Inject 4+2 bunches
$h = 7$
$h = 21$
γ_{tr}
Eject 72 bunches
$h = 84$

B [T]

→ Each bunch from the Booster divided by 12 → 6 × 3 × 2 × 2 = 72

Triple splitting in the PS
Two times double splitting in the PS

Two times double splitting and bunch rotation:
- Bunch is divided twice using RF systems at
  h = 21/42 (10/20 MHz) and h = 42/84 (20/40 MHz)

- Bunch rotation: first part h84 only + h168 (80 MHz) for final part

Summary

- Cyclotrons/Synchrocylotrons for low energy

- Synchrotrons for high energies
  constant orbit, rising field and frequency

- Particles with higher energy have a longer orbit (normally) but a higher velocity
  - at low energies (below transition) velocity increase dominates
  - at high energies (above transition) velocity almost constant

- Particles perform oscillations around synchronous phase
  - synchronous phase depending on acceleration
  - below or above transition

- bucket is the region in phase space for stable oscillations

- matching the shape of the bunch to the bucket is important

Appendix: First Energy-Phase Equation
$$f_{RF} = h f_r \quad \Rightarrow \quad \Delta\phi = -h\,\Delta\theta \quad with \quad \theta = \int \omega\, dt$$

particle ahead arrives earlier
=> smaller RF phase

For a given particle with respect to the reference one:

$$\Delta\omega = \frac{d}{dt}(\Delta\theta) = -\frac{1}{h}\frac{d}{dt}(\Delta\phi) = -\frac{1}{h}\frac{d\phi}{dt}$$

Since: $\quad \eta = \frac{p_s}{\omega_{rs}}\left(\frac{d\omega}{dp}\right)_s \quad$ and

$$E^2 = E_0^2 + p^2 c^2$$

$$\Delta E = v_s \Delta p = \omega_{rs} R_s \Delta p$$

one gets:
$$\frac{\Delta E}{\omega_{rs}} = -\frac{p_s R_s}{h\eta\omega_{rs}}\frac{d(\Delta\phi)}{dt} = -\frac{p_s R_s}{h\eta\omega_{rs}}\dot{\phi}$$

Appendix: Second Energy-Phase Equation

The rate of energy gained by a particle is:
$$\frac{dE}{dt} = e\hat{V}\sin\phi\,\frac{\omega_r}{2\pi}$$

The rate of relative energy gain with respect to the reference particle is then:
$$2\pi\Delta\left(\frac{\dot{E}}{\omega_r}\right) = e\hat{V}(\sin\phi - \sin\phi_s)$$

Expanding the left-hand side to first order:
$$\Delta\left(\dot{E}T_r\right) \cong \dot{E}\Delta T_r + T_{rs}\Delta\dot{E} = \Delta E\dot{T}_r + T_{rs}\Delta\dot{E} = \frac{d}{dt}\left(T_{rs}\Delta E\right)$$

leads to the second energy-phase equation:
$$2\pi\frac{d}{dt}\left(\frac{\Delta E}{\omega_{rs}}\right) = e\hat{V}\left(\sin\phi - \sin\phi_s\right)$$
Appendix: Stationary Bucket - Separatrix

This is the case sinϕ_s=0 (no acceleration) which means ϕ_s=**0** or π . The equation of the separatrix for ϕ_s= π (above transition) becomes:

$$\frac{\dot{\phi}^2}{2} + \Omega_s^2\cos\phi = \Omega_s^2 \qquad\qquad \frac{\dot{\phi}^2}{2} = 2\Omega_s^2\sin^2\frac{\phi}{2}$$

Replacing the phase derivative by the (canonical) variable W:

$$W = \frac{\Delta E}{\omega_{rf}} = -\frac{p_s R_s}{h\eta\omega_{rf}}\dot{\varphi}$$

and introducing the expression for Ω_s leads to the following equation for the separatrix:

with C=2πR$_s$

$$W = \pm\frac{C}{\pi hc}\sqrt{\frac{-e\hat{V}E_s}{2\pi h\eta}}\sin\frac{\phi}{2} = \pm W_{bk}\sin\frac{\phi}{2}$$

Stationary Bucket (2)

Setting $\phi=\pi$ in the previous equation gives the height of the bucket:

$$W_{bk} = \frac{C}{\pi h c}\sqrt{\frac{-e\hat{V}E_s}{2\pi h\eta}}$$

This results in the maximum energy acceptance:

$$\Delta E_{max} = \omega_{rf}W_{bk} = \beta_s\sqrt{2\frac{-e\hat{V}_{RF}E_s}{\pi\eta h}}$$

The area of the bucket is:
$$A_{bk} = 2\int_0^{2\pi}W\,d\phi$$
Since:
$$\int_0^{2\pi}\sin\frac{\phi}{2}\,d\phi = 4$$

one gets:
$$A_{bk} = 8W_{bk} = 8\frac{C}{\pi h c}\sqrt{\frac{-e\hat{V}E_s}{2\pi h\eta}} \longrightarrow W_{bk} = \frac{A_{bk}}{8}$$

Bunch Matching into a Stationary Bucket

A particle trajectory inside the separatrix is described by the equation:

$$\frac{\dot{\phi}^2}{2} - \frac{\Omega_s^2}{\cos\phi_s}(\cos\phi+\phi\sin\phi_s)=I \quad \xrightarrow{\phi_s=\pi} \quad \frac{\dot{\phi}^2}{2}+\Omega_s^2\cos\phi=I$$

The points where the trajectory crosses the axis are symmetric with respect to $\phi_s=\pi$

$$\frac{\dot{\phi}^2}{2}+\Omega_s^2\cos\phi=\Omega_s^2\cos\phi_m$$

$$\dot{\phi}=\pm\Omega_s\sqrt{2(\cos\phi_m-\cos\phi)}$$

$$W = \pm W_{bk}\sqrt{\cos^2\frac{\varphi_m}{2}-\cos^2\frac{\varphi}{2}}$$

$$\cos(\phi) = 2\cos^2\frac{\phi}{2}-1$$

Bunch Matching into a Stationary Bucket (2)

Setting $\phi = \pi$ in the previous formula allows to calculate the bunch height:

$$W_b = W_{bk} \cos\frac{\phi_m}{2} = W_{bk} \sin\frac{\hat{\phi}}{2}$$

or:

$$W_b = \frac{A_{bk}}{8} \cos\frac{\phi_m}{2}$$

$$\longrightarrow \quad \left(\frac{\Delta E}{E_s}\right)_b = \left(\frac{\Delta E}{E_s}\right)_{RF} \cos\frac{\phi_m}{2} = \left(\frac{\Delta E}{E_s}\right)_{RF} \sin\frac{\hat{\phi}}{2}$$

This formula shows that for a given bunch energy spread the proper matching of a shorter bunch (ϕ_m close to π, $\hat{\phi}$ small) will require a bigger RF acceptance, hence a higher voltage

For small oscillation amplitudes the equation of the ellipse reduces to:

$$W = \frac{A_{bk}}{16} \sqrt{\hat{\phi}^2 - (\Delta\phi)^2} \qquad \longrightarrow \qquad \left(\frac{16W}{A_{bk}\hat{\phi}}\right)^2 + \left(\frac{\Delta\phi}{\hat{\phi}}\right)^2 = 1$$

Ellipse area is called longitudinal emittance

$$A_b = \frac{\pi}{16} A_{bk} \hat{\phi}^2$$
