Future prospects for NA61 heavy ions: rare observables

Connecting to high-energy (RHIC) results

M. van Leeuwen, Utrecht University
and the NA61 collaboration

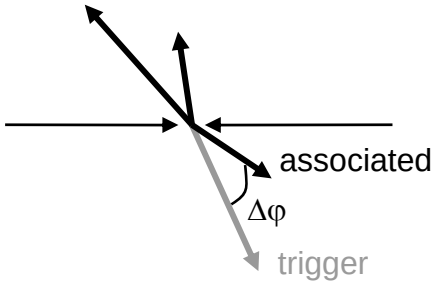
Workshop:
New Opportunities in the Physics Landscape at CERN
11-14 May 2009

Motivation

- Heavy ion collisions: study strong interactions bulk matter
  - Identify phase transition to Quark-Gluon-Plasma
- Pure bulk = soft QCD, theoretically difficult
- Hard-soft interplay studied at RHIC shows many unexpected results – do these effects exist at SPS energies?
  - Can we ‘switch off’ some effects – transition ?

Jet-like di-hadron correlations at RHIC

STAR, PRL97, 162301



$8 < p_T^{trig} < 15$ GeV

$p_T^{assoc} > 3$ GeV

Combinatorial background

p+p event display

Near side **Away side**

Use di-hadron correlations to probe the jet-structure in p+p, d+Au and Au+Au

At high $p_T > 4$-6 GeV: Clear di-jet signature
Away-side suppression due to energy loss

Lowering p_T: bulk response?

d+Au, 200 GeV

$3.0 < p_T^{trig} < 4.0$ GeV/c

$1.3 < p_T^{assoc} < 1.8$ GeV/c

Jet-like peak

Au+Au 0-10%

STAR preliminary

$3 < p_{t,trigger} < 4$ GeV

$p_{t,assoc.} > 2$ GeV

STAR, Putschke et al

STAR, M. Horner, M. van Leeuwen, et al

Near side
Enhanced yield in Au+Au

Away-side:
Strong broadening in central Au+Au
'Dip' at $\Delta\varphi = \pi$

`Ridge': associated yield at large $\Delta\eta$
$dN/d\Delta\eta$ approx. independent of $\Delta\eta$

Large modifications of di-hadron structure at intermediate p_T
Modified fragmentation? Bulk response?

Comparing SPS and RHIC

CERES, NA49 158 *A*GeV

M. Szuba, Hot Quarks 2008

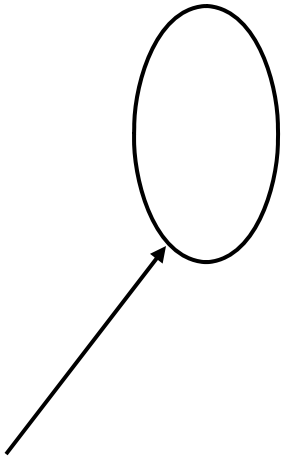
SPS full energy: di-hadron structure similar to RHIC
yields lower $\Rightarrow$ lower ‘jet’ energy

Energy dependence of di-hadron correlations at SPS

40 *A*GeV

20 *A*GeV

M. Szuba, HQ08



Qualitative change from low to high energy:
from near-side dip to near-side peak

Clear turn-on as a function of energy. What is the mechanism?

New data needed to study η, p_T-dependence, above and below transition

Charm production at RHIC

$$R_{AA} = \frac{dN/dp_T|_{Au+Au}}{N_{coll}\, dN/dp_T|_{p+p}}$$

STAR, PRL 98 (2007) 192301

Low p_T, $R_{AA} \sim 1$
Total cross section scales with N_{coll} as expected

Suppression at high-p_t:
charm interacts with medium

Does charm thermalise?

Measure charm spectra at low p_t, v_2

Will be measured at RHIC (STAR, PHENIX upgrades)
and LHC (ALICE, ...)
Can we measure this at SPS? Thermalised charm at SPS?

Charm with NA61?

NA49: $D^0 \rightarrow K\,\pi$

3.8M events

$N(D^0+\overline{D^0}) = -0.36 \pm 0.74$ per event

$N(D^0+\overline{D^0}) < 1.5$ per event (C.L. 98%)

Phys.Rev.C73:034910,2006

NA61: $c \rightarrow \mu^+ \mu^-$

$$\sigma_{c\bar{c}}^{pp} = 9.5 \pm 1.3 \pm 1.4\ \mu b$$

EPJ C59, 607

$N(D^0+\overline{D^0})$ expected:

~ 0.11 per central event

Would need ~300M events (300 days running) for 1σ

$\Rightarrow$ Need vertex detector to measure D^0, p_T spectra, v_2

e.g. 20M central events gives 80k $D^0 \rightarrow K\,\pi$

Technology candidate: GOSSIP

H. van der Graaf et al., NIKHEF

GridPix/InGrid

GOSSIP

Gas on Slimmed Silicon Pixels

Gas amplification + pixel readout

Use time-dependence to image track in gas layer

Pixel size 55 x 55 μm
+ time

Thin, precise and cheap !

Occupancy for vertex detector

Hits at z = 10 cm

2-track distance

$y_{cms} < 1$

Central Pb+Pb at 158 AGeV

For y < 4 ~ R > 0.3 cm, two-track distance ~ 300 μm

z = 10 cm safe choice for first plane

Vertex resolution with vertex detector

Decay distance along beam

158 *A*GeV collisions

Decay length resolution

Including Mult scatt ~600 μm Si per plane

Lorentz boost: large decay lengths (mm scale)

Geometry:
6 planes, 10, 15 … 40 cm

Looks promising: typical decay length >> resolution

Summary of proposal

- 2 runs of NA61 ~10 weeks, 70M events
  (after baseline heavy ion program, 2014+)
  - Highest SPS energy: 158 AGeV
  - Low energy: 20/30 AGeV
- Measurement 1: jet-like di-hadron structure
  - Peak-dip transition, explore p_T-dependence, η-φ structure – connection to bulk response effects at RHIC
- Measurement 2: charm production
  - Need vertex detector
  - Measure yield, p_T spectra (radial flow) and v_2

Reflections about EXChALIBUR, the exclusive 4π detector for EXCLUSIVE measurements of hadronic interactions needed for deeper understanding of QCD

G. Vesztergombi

Presented on the Workshop:

New opportunities in the physics landscape at CERN

11/13 May ’09
Geneva

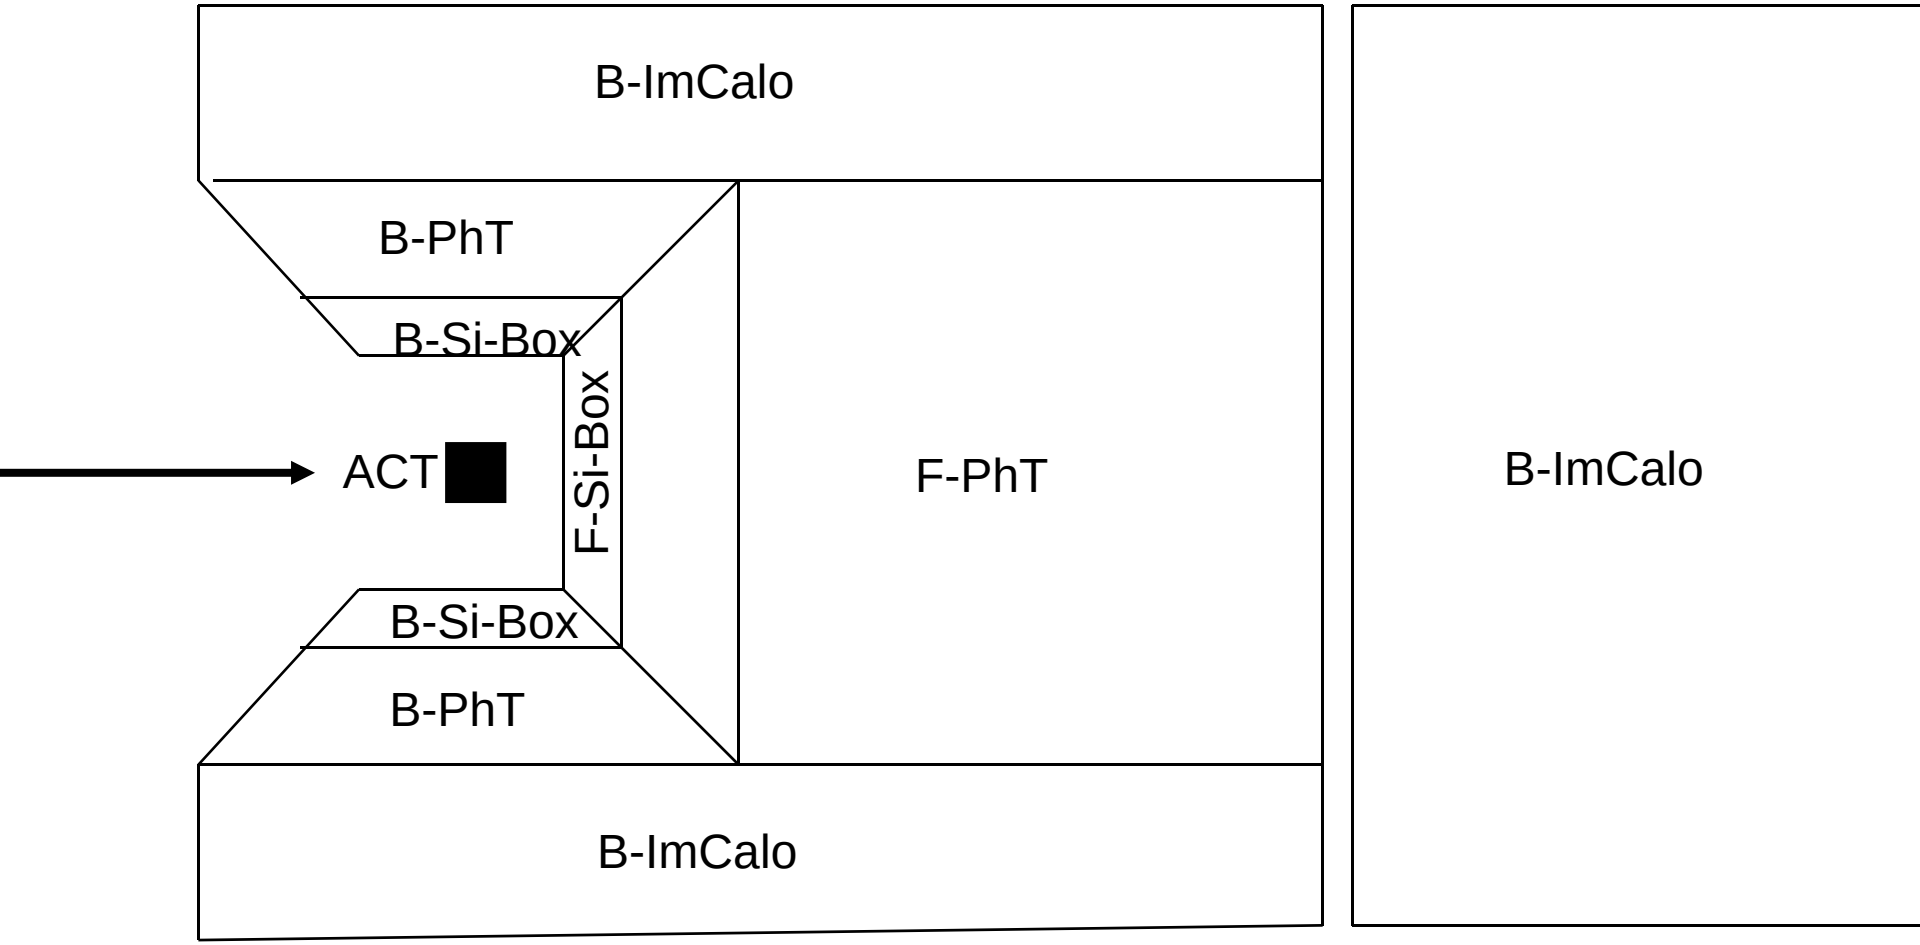
Towards a 4π detector?

Concept: a large acceptance detector for 'all' particles (EM + charged hadrons + neutral hadrons) to perform exclusive measurements of hadron production at the SPS energy range.

- Qualitative step forward in hadron production experiments
- Goal: address unsolved issues from ISR era:
  - Cronin effect – connection to long range correlations?
  - Changeover/interplay soft-hard production – emergence of jetty structure
  - Baryon formation/transfer
  - Others?

SPS has the potential to address many of these issues: wide energy range and choice of beams to narrow down the 'model space'

EXChALIBUR

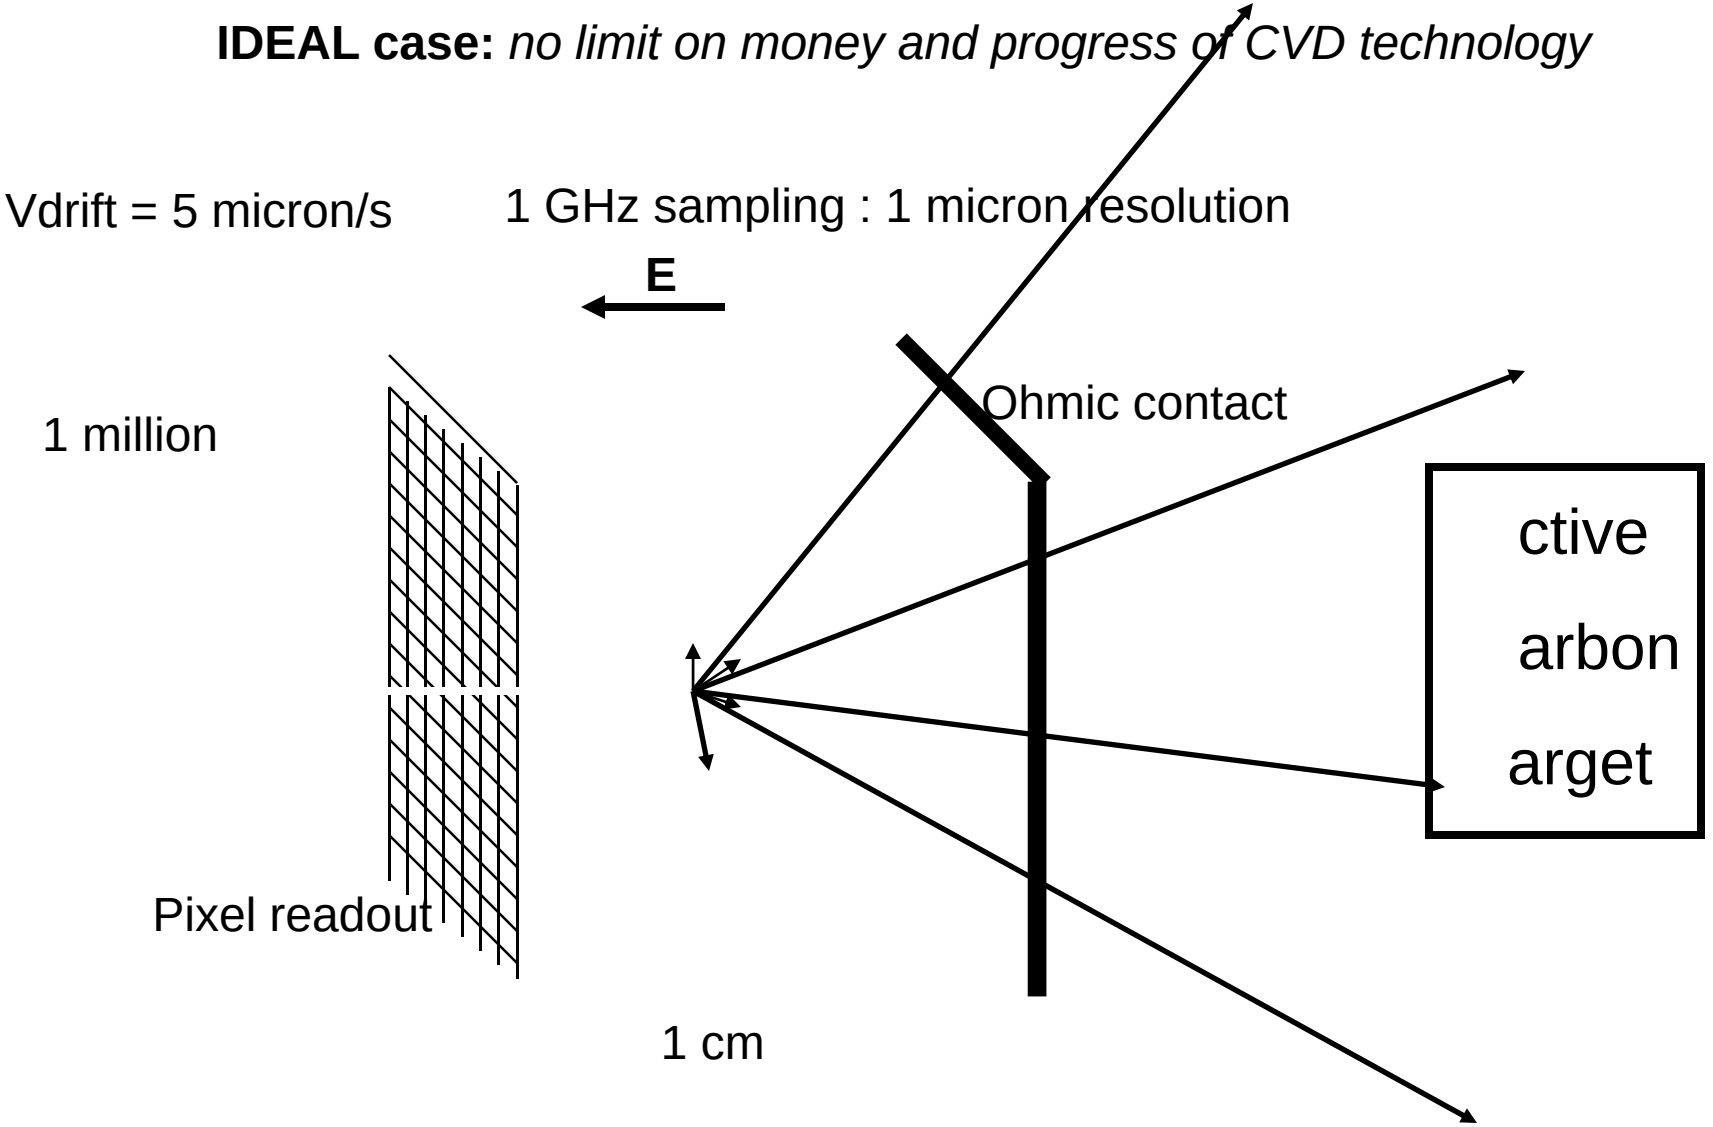


Dipol Magnetic Field (1 Tesla)

Conceptual lay-out of a possible new 4π detector system

DIAMOND-TPC

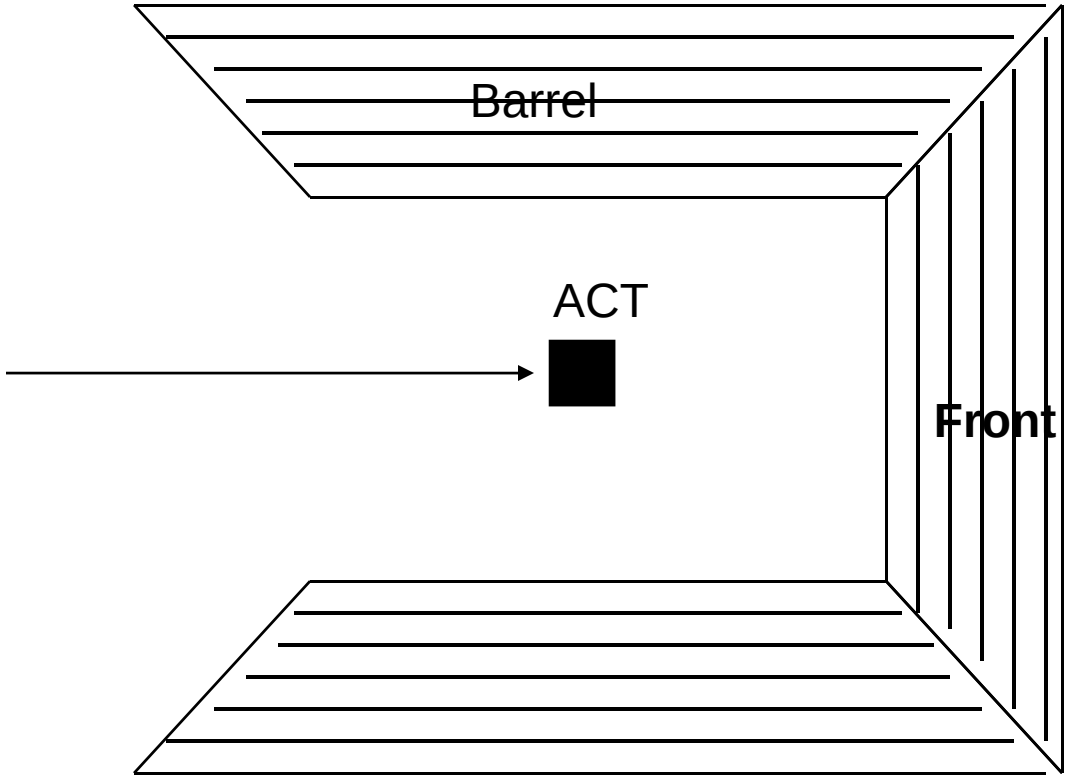
IDEAL case: *no limit on money and progress of CVD technology*



Carbon target, with full measurement of recoils

Si-Box

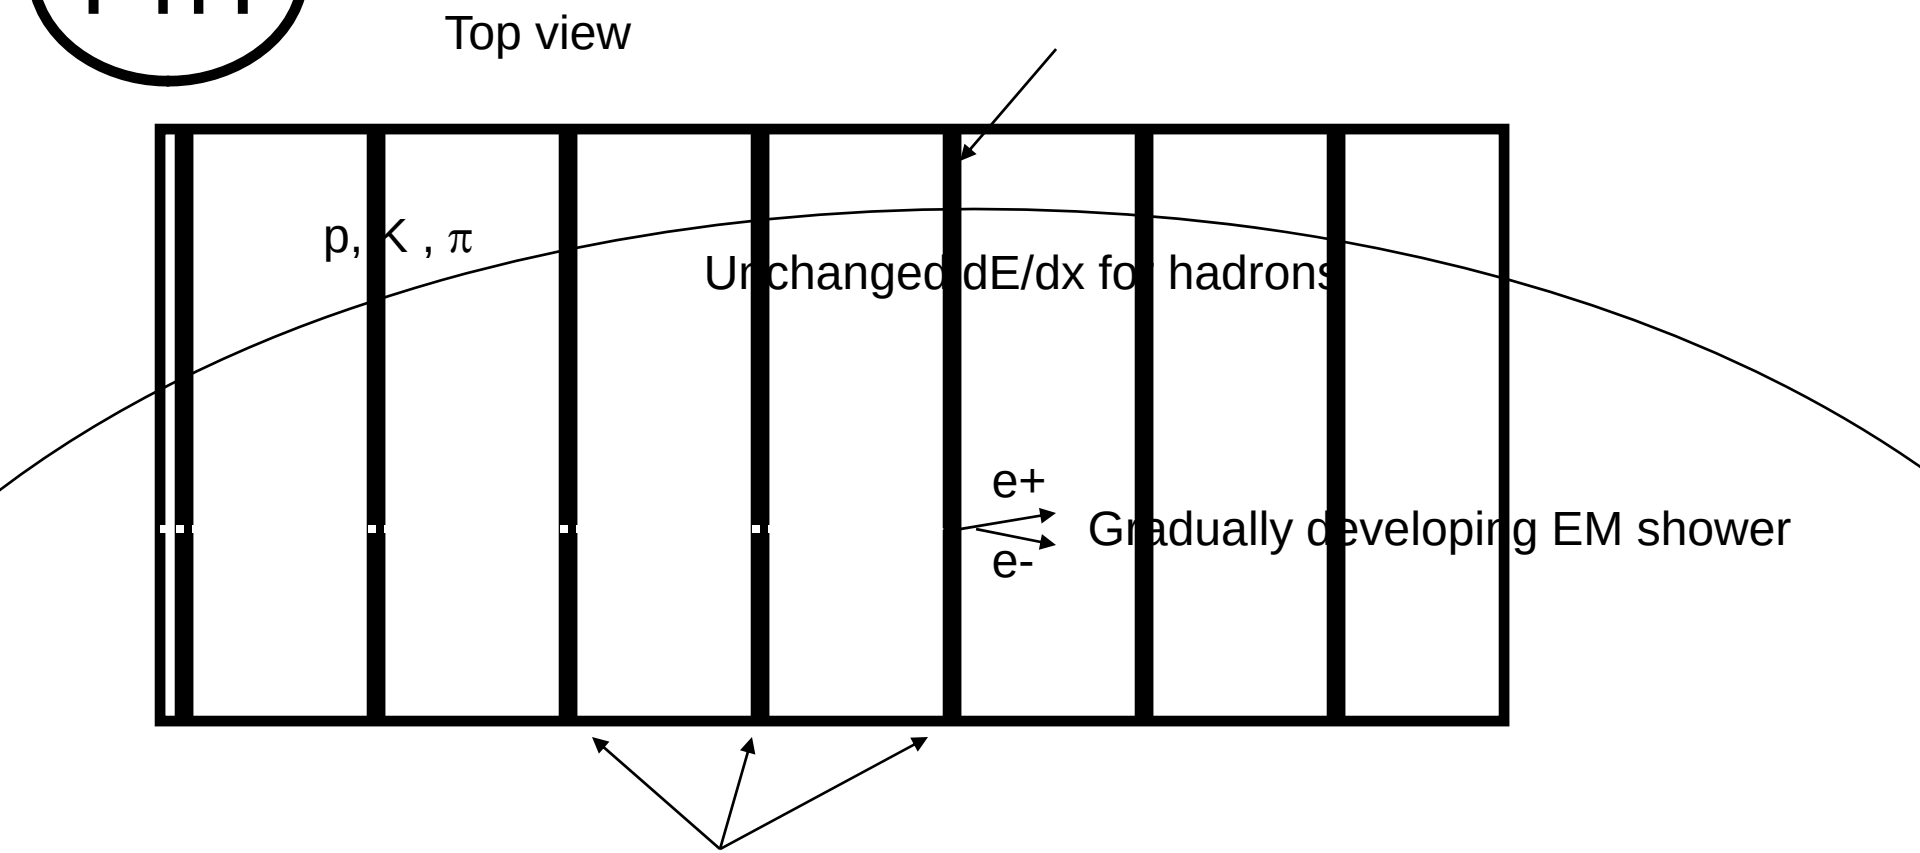
Low-momentum and vertex tracking



5 SDD layers

PhotonTracker

PhT



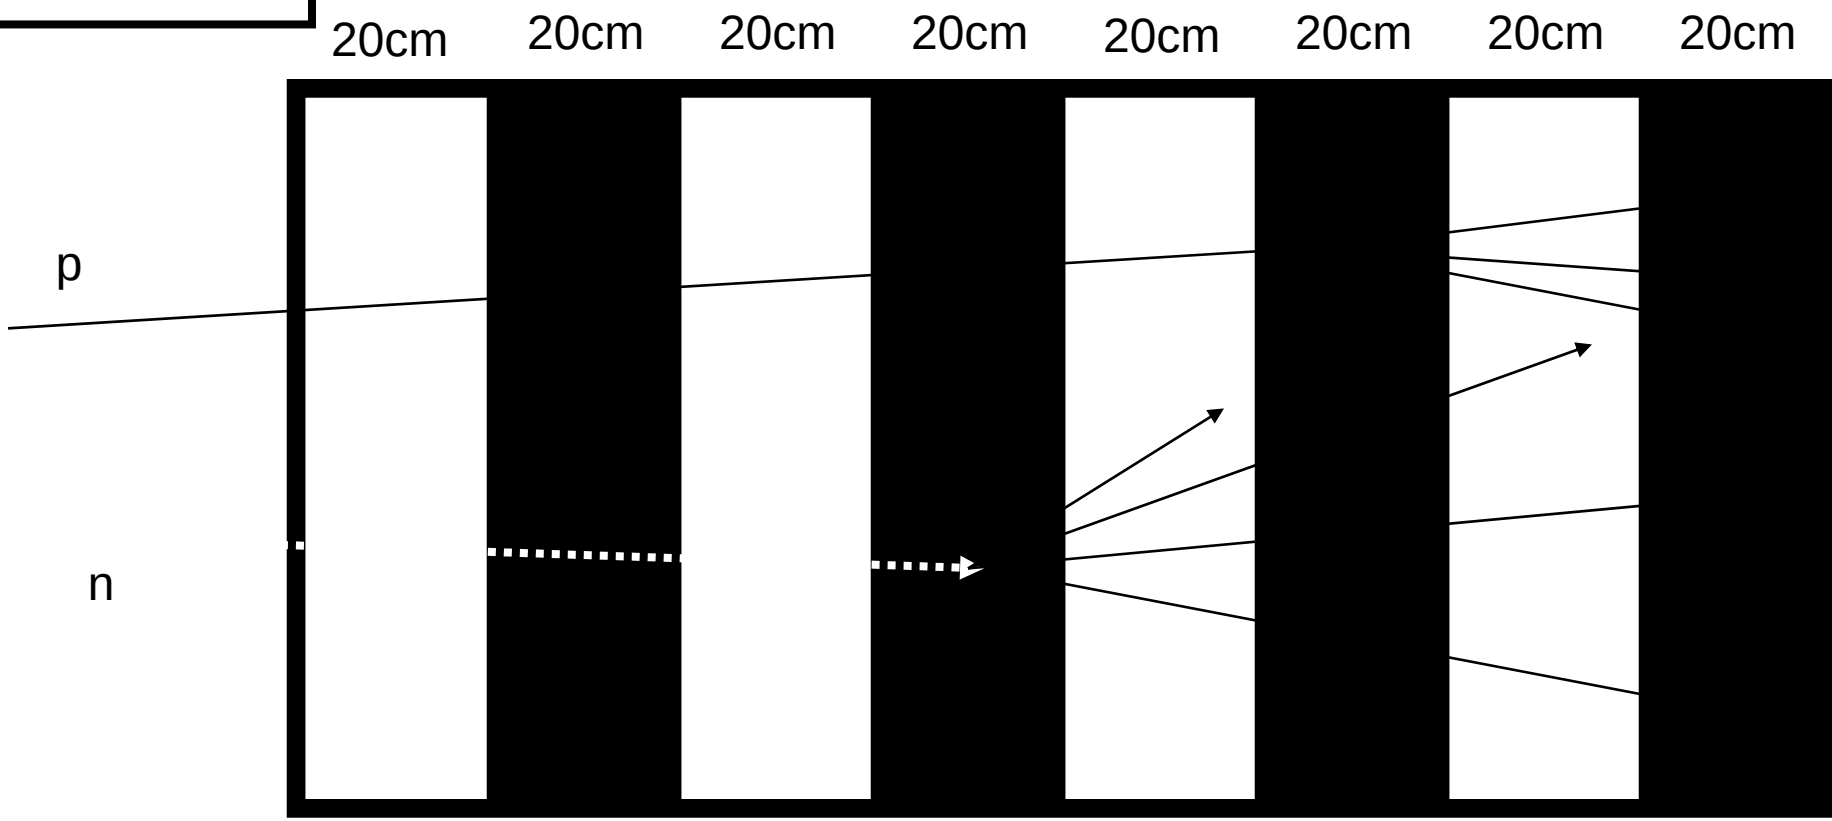
Standard TPC with W-strips in 1Tesla magnetic field

25 cm cells with 0.8mm = 0.25 Xo W-converters where λ interaction length=30Xo

20 cells : total 5 Xo and only 0.17 λ interaction length, NOEFFECT for p, K, π

ImCalo

Impact Calorimeter



TPC with polyethylene hadron interaction volumes

TPC pad readout pattern is optimized for local vertex reconstruction
20 cm Polyethylene: 0.47 Xo and 0.25 λ interaction length
16 periods gives total length 6.4 m with 4 λ interaction length
Showers from charged hadrons can be used for calibration.

DAQ

Unbiased sampling with trigger-less read out

Beam intensity: 10^5 - 10^6 particle/s , spot size sigma = 2 mm

Interaction rate: 100 – 1000 ev/s

Each channel is continuously read out by a token ring.

Parallel processing by SIMD farm

Each hit has LOCALITY (XY) + TIME(t) + AMPLITUDE(Energy) Recorded.

DATA DRIVEN System: Single hits are looking for association with others relying on locality and time.
Successfull associations create OBJECTs.
Simpler objects are building up higher classes….

Due to the fact that in this region the **multiplicities** are still relatively **modest** one have more chance to identify characteristic features.
Bohr was using the spectral lines of Hydrogen and not the ones of Lead.

In short: We should find "the Lyman and Balmer series" for QCD. Due to the fact that QCD is so many times more complicated than QED we need EXA-Bytes instead of the few Bytes of Bohr.

The complication is mainly arising from the fact that the
in contrast to point-like leptons. In this situation one should grab any possibility to collect new information which can provide

The aim of this proposal calls for not an immediate concrete action, but to initiate the discussion for a longer range project which could lead to definite design of a dedicated exclusive experiment in 5 years from now.

It is clear, that exclusive experiments have more information than the inclusive ones, what is not clear, is this information enough for a breakthrough.

Pessimists can say: *There is no such information*.
But I ask: *Please prove it without trying to measure it!*
