

# 16 T dipole in common coil configuration: electromagnetic design

T. Martinez, J. Munilla, F. Toral - CIEMAT

# Outline

---

- Introduction
- 2-D magnetic design without ancillary coils
- 2-D magnetic design with ancillary coils
- Conclusions

# Introduction (I)

- The common coil layout is based on two flat coils.
- A unique support structure for two apertures, placed at the same vertical plane.
- Main advantage: pure flat coils.
- Disadvantages: large stored energy and electromagnetic forces, complicated assembly.
- Traditionally, American labs (BNL, LBNL, Fermilab) have worked on this layout, also for high fields.
- Chinese colleagues (IHEP) are now working on a 20-Tesla dipole design based on common coils.
- In the framework of EuroCirCol project, CIEMAT is working on a 16-Tesla dipole design based on common coils.

# Introduction (II)

- The starting parameters are common for the three design options under study in the EuroCircol framework (cos-theta, block and common coil):

COMMON STARTING PARAMETERS FOR THE MAGNET OPTIMIZATION

|   |                 |                                       |
|---|-----------------|---------------------------------------|
| Dipole field at aperture                              | 16              | T                                     |
| Aperture diameter                                     | 50              | mm                                    |
| Reference radius                                      | 17              | mm                                    |
| Beam-to-beam distance                                 | 250             | mm                                    |
| Outer diameter  | 800             | mm                                    |
| Cryostat outer diameter                               | 1000            | mm                                    |
| Operating margin (nominal current is 90% on loadline) | $\geq 10$       | %                                     |
| Nominal current                                       | $\geq 9000$     | A                                     |
| Working temperature                                   | 4.2             | K                                     |
| Cable insulation thickness                            | 0.15            | mm per conductor face                 |
| Inter-layer insulation thickness                      | 0.5             | mm                                    |
| Minimum ground insulation thickness                   | 2               | mm                                    |
| X-section multipoles (geometric)                      | A few $10^{-4}$ | units at reference radius             |
| Overall coil length                                   | 14              | m                                     |
| Peak temperature                                      | 350             | K (quench at 105% of nominal current) |
| Peak voltage to ground                                | 2000            | V (quench at 105% of nominal current) |
| Peak inter-turn voltage                               | 100             | V (quench at 105% of nominal current) |
| Protection circuit delay                              | 40              | ms                                    |

# 2-D magnetic design

- The influence of a number of parameters has been analyzed to optimize the 2-D magnetic design and to better understand the **sensitivity factors**:
  - Ancillary coils.
  - Intra-beam distance.
  - Iron outer diameter.
  - Strand diameter.
  - Number of coils.
  - Nominal current (intrinsically, cable size).
  - Internal splices.
  - Magnet protection.
- Main objective: **minimum volume of superconductor** while achieving the requirements in the previous Table.
- **Self field** is not included in these calculations. If included, working point on load line increases about 1%.
- Only double pancake coils are considered in this study.
- Field lines surround the coil blocks.

*Common coil without ancillary coils*

*Common coil with ancillary coils*

# 2-D magnetic design optimization **without** ancillary coils

- In a first stage, we have considered only the main coils.
- The main advantages would be:
  - Less coils to be produced, in order to save tooling and time of reaction.
  - Easier mechanical assembly:
    - Less parts to be assembled.
    - No forces on the coil blocks towards the aperture.

# Sensitivity analysis of intra-beam distance

- A short intra-beam distance implies a strong cross-talk between apertures:
  - The superconductor efficiency decreases with the intra-beam distance.
  - The field quality is more difficult to achieve with short intra-beam distance.
- **Conclusion:** we keep **320 mm** as intra-beam distance.

| Intra-beam distance                  | 280   | 320   | 360 mm              |
|--------------------------------------|-------|-------|---------------------|
| Nominal current                      | 8910  | 9030  | 9025 A              |
| Intra-beam distance                  | 280   | 320   | 360 mm              |
| Iron outer diameter                  | 750   | 750   | 750 mm              |
| Strand area per magnet               | 290   | 266   | 260 cm <sup>2</sup> |
| Total FCC SC weight                  | 16157 | 14816 | 14485 ton           |
| Strand area per magnet Cu:Sc=1       | 255   | 214   | 209 cm <sup>2</sup> |
| Total FCC SC weight Cu:Sc=1          | 14197 | 11933 | 11679 ton           |

| Sum_fx                               | 19.27 | 20.08 | 19.88 MN/m          |
| Sum_fy                               | 3.67  | 1.82  | 1.15 MN/m           |
| Stray field at 50 mm off iron yoke   | 0.78  | 1.1   | 1.25 T              |
| Stray field at 1 m off magnet center | 47    | 56    | 62 mT               |

# Sensitivity analysis of iron outer diameter

- No significant saving of superconductor with more iron due to the strong saturation.
- Fringe field slightly decreases with more iron.
- It is better to use that space for the outer shell: increase stiffness of support structure.
- **Conclusion:** we keep **750 mm** as iron yoke outer radius.

| Iron outer diameter            | 750   | 800   | mm              |
|--------------------------------|-------|-------|-----------------|
| Nominal current                | 9030  | 9030  | A               |

| Stray field 1 m                | 56    | 51    | mT              |

# Sensitivity analysis of strand diameter

- With larger strand diameter, the engineering current density is higher. Therefore, the superconductor efficiency increases.
- Conclusion:** it is better to use a strand so large as possible (1.1 mm diameter).

| Strand diameter                | 1     | 1.1 mm              |
|--------------------------------|-------|---------------------|
| Nominal current                | 9000  | 9030 A              |
| Intra-beam distance            | 320   | 320 mm              |
| Iron outer diameter            | 750   | 750 mm              |
| Strand area per magnet         | 276   | 266 cm <sup>2</sup> |
| Total FCC SC weight            | 15391 | 14816 ton           |
| Strand area per magnet Cu:Sc=1 | 229   | 214 cm <sup>2</sup> |
| Total FCC SC weight Cu:Sc=1    | 12773 | 11933 ton           |
| margin on load line            | 90.3  | 89.7 %              |
| #block                         | 9     | 1                   |
| peak field                     | 16.49 | 16.43 T             |
| b3                             | -1.7  | 0.1 units           |
| b5                             | -4.5  | -6.3 units          |

| Stray field 1 m                | 59    | 56 mT               |

# Sensitivity analysis of nominal current

- If both layers of the high field coil are made with the same cable, the outer layer has a low working point on the load line. Inside the same cable, field is quite different between the strands. Field lines are quite parallel to the high field coil.
- The effect on magnet protection is not analyzed at this stage.
- **Conclusion:** it is better to stick to the minimum allowable current (9 kA).

| Nominal current                | 9030  | 10025 | A               |
|--------------------------------|-------|-------|-----------------|

# Sensitivity analysis of the number of coils

- Intrinsically, the current is larger for a two-coil layout. Without internal splices, the superconductor efficiency is poor in the outer layer.
- **Conclusion:** As expected, it is better to use **three coils**.

| Number of coils                | 3            | 2            |                 |

# Sensitivity analysis of internal splices

- Superconductor efficiency increases noticeably if one uses different cable size for each layer of the high field coil.
- Conclusion:** we will keep an **internal splice in the high field coil.**

| Internal splice at high field coil | NO    | YES   |                 |
|------------------------------------|-------|-------|-----------------|
| Nominal current                    | 9030  | 9025  | A               |

# 2-D magnetic design: magnet protection

- All the coils are quenched by heaters (see T. Salmi's talk). Thanks a lot to Tiina for the spreadsheet to compute hot-spot temperatures.
- Except the high field coil (minimum Cu:Sc ratio is 1), all the coils should reach a hotspot temperature as close as possible to 350 K: it helps to get a uniform temperature map. High temperature gradient at the high field cable interface.
- Voltages from coil to ground are high for 9 kA nominal current. Higher currents are possible but superconductor efficiency decreases.
- Quench heater assembly is very easy in these flat coils.
- **Conclusion:** hotspot temperature close to 350K in **all** the coils.

# Optimal solution without ancillary coils

- Summary:** 320 mm intra-beam distance, 750 mm iron outer diameter, 9 kA nominal current, three coils, internal splice at high field coil, hotspot temperature close to 350K in all the coils.
- Iron shape is customized to decrease the multipole field variation with current.

# 2-D magnetic design at 1.9 K

- The low field coil can be made with NbTi when working temperature is 1.9 K.
- In a Nb<sub>3</sub>Sn based design, about 12500 tons are necessary. In this alternative design, 10100 tons of Nb<sub>3</sub>Sn are needed, together with 3000 tons of NbTi.
- **Conclusion:** low field coil should be made in NbTi if working temperature is 1.9 K.

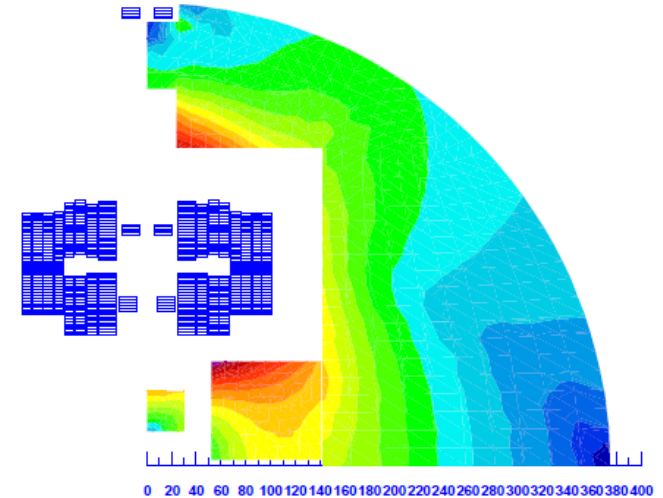

# Outline

---

- Introduction
- 2-D magnetic design without ancillary coils
- 2-D magnetic design with ancillary coils
- Conclusions

# 2-D magnetic design optimization **without** ancillary coils

- In this second stage, ancillary coils are included in the layout. They are flat, although flared ends are possible, saving two coils.
- It is strongly recommended by Ramesh Gupta (BNL) and Qingjin Xu (IHEP) during last FCC Week.
- Optimization is more efficient in Roxie when using absolute positions of coil blocks as design variables instead of relative ones (thanks to B. Auchmann).
- The main advantages of this layout would be:
  - Enhanced superconductor efficiency. Optimal aspect ratio of block is around 1.5 (width/height).
  - Shorter cable unit length (less turns per coil).
  - Cross-talk reduction: intra beam distance can be shortened.
  - Large bending radius: react and wind coils.
  - Outer iron radius could be reduced.

# Optimal solution with ancillary coils

- **Summary:** 320 mm intra-beam distance, 750 mm iron outer diameter, 9 kA nominal current, four main coils, internal splice at high field coil, hotspot temperature close to 350K in all the coils.
- Iron shape is customized to decrease the multipole field variation with current.

# Magnetic design with ancillary coils: sensitivity analysis of intra beam distance

- Cross-talk between apertures is now weaker:
  - The superconductor efficiency slightly decreases with the intra-beam distance.
  - The field quality achievable with short intra-beam distance.
- **Conclusion: 280 mm** could be the intra beam distance, with a smaller iron outer radius.

| Intra-beam distance            | 320   | 280   | mm              |

| Stray field 1 m                | 46    | 39    | mT              |

# Final considerations: how to go on?

- The cross section is very similar to the block design. The amount of superconductor to provide 16 T field is not very different from other layouts if using ancillary coils.
- The main advantage of the common coil layout is that all **the coils are flat**.
- The main disadvantage is the high **induced voltage during quench** (see T. Salmi's talk):
  - **Stored energy** is larger in the common coil than in the other layouts because there is not common flux between both apertures.
    - It does not decrease with the intrabeam distance, only with the coil size. Engineering current density should be increased: decrease safety margin.
  - **Current should be larger**: the best solution would be to increase the strand diameter or the current density (lower Cu to Sc ratio or safety margin). To increase the number of strands would decrease the superconductor efficiency.
  - Analyze the **connections** between coils to decrease the voltages.
- The thermal gradient between the high field layer and the rest of coils can be reduced by decreasing the Cu to Sc ratio in that cable or RRR (impact on stability??).

# Conclusions

---

- 2-D magnetic optimization of common coil layout for a 16-T dipole has been done.
- Superconductor efficiency is lower than cos-theta or block configurations, but it can be kept moderate if implementing an internal splice at the high field coil, large strands and low nominal current.
- Superconductor efficiency is further enhanced by the use of ancillary coils, although the assembly is more difficult.
- With ancillary coils, the cross section is very similar to block layout. Only differs in the stored energy and the cross talk.
- Low field coil can be made in NbTi if working temperature is 1.9 K.
- High voltages to ground during quench could be decreased with larger currents or higher engineering current density.
- Sensitivity analysis is ongoing, to be used in the cost study: different values of nominal field, load margin and aperture.

# A Few Parameters of Preliminary 16 T Common Coil PoP Dipole

**Aperture : 50 mm**  
**Bore Field: 16.05 T**  
**Current: 10.6 kA**

**Stored Energy  
(per aperture) : 1.8 MJ/m**

**Peak field : 16.62 T**

**Peak Enhancement = 3.6%**

**Conductor: Same as used in FNAL design**
