# Layered View of Distributed Cyberinfrastructure

---

- L4: Application
    - Development of distributed applications and scientific workflows.
  - L3: Workload Exec. & Management (**WEM**)
    - Task distribution and resource selection
  - L2: Workload Run-time System (**WRTS**)
    - Managing tasks on a resource.
  - L1: Resource Layer.
    - HPC, Grids, Clouds or specialized (data) infrastructure.
- 
- The diagram illustrates the four layers of distributed cyberinfrastructure. It consists of four rectangular boxes arranged vertically, each labeled with its corresponding layer level (L1, L2, L3, L4) and a descriptive title. Dotted lines connect the top of each box to the bottom of the next, indicating the hierarchical relationship between the layers. The boxes are arranged from bottom to top as follows: L1 (Resource Layer), L2 (Workload Run-time System), L3 (Workload Exec. & Management), and L4 (Application). The Resource Layer box contains three sub-boxes: HPC, Grids, and Clouds. The WEM box contains two sub-boxes: Workload Execution and Management and Scientific Applications. The WRTS box contains one sub-box: Workload Run Time System.
- | Layer | Description  |
|-------|--|
| L1    | Resources: HPC, Grids, Clouds                          |
| L2    | Workload Run-time System                               |
| L3    | Workload Exec. & Management<br>Scientific Applications |
| L4    | Application  |

## **Software and Tools: Challenges**

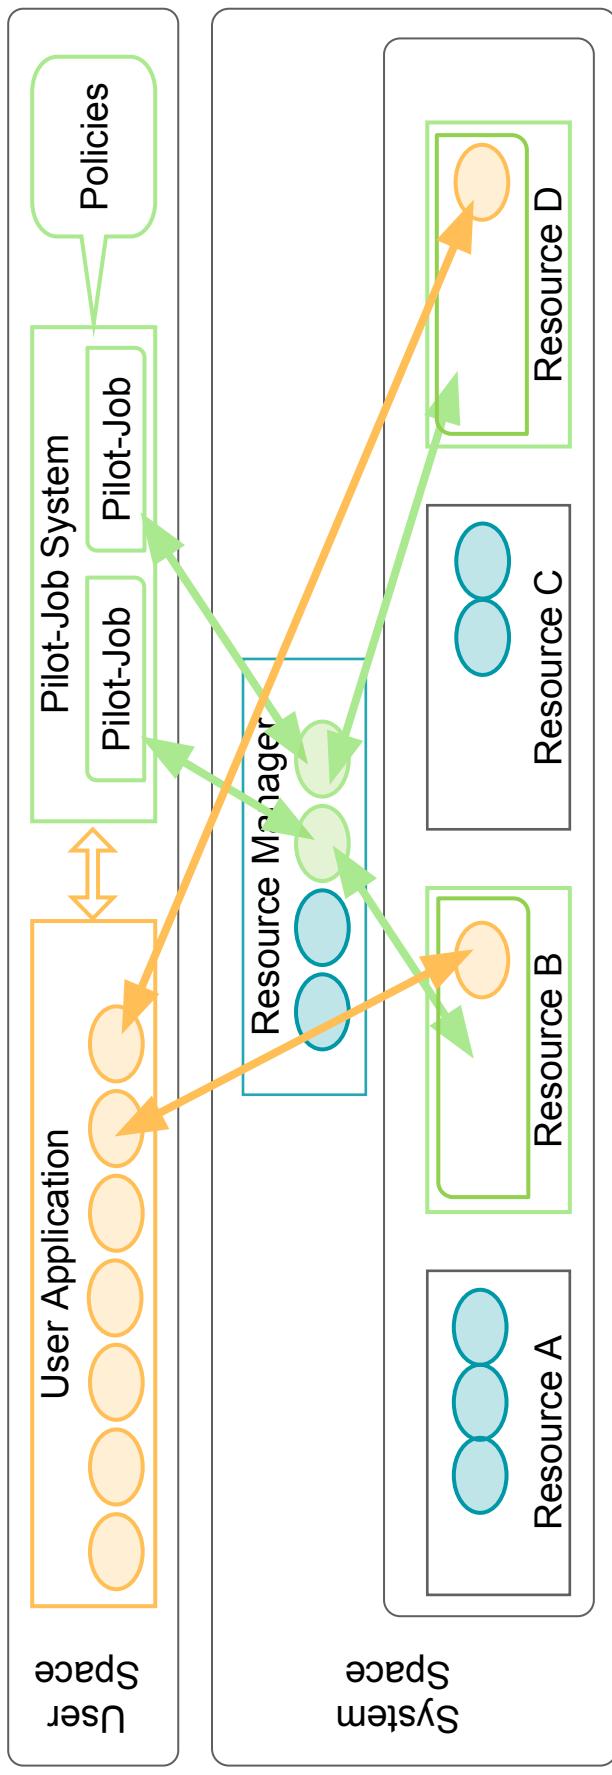

---

- How to find balance between requirements and distinct solutions?
  - Build upon commonality, yet provide for distinctiveness
  - How to balance “specific” “general-purpose” and “functionally extensible”?
  - Reduce software development while meeting performance requirements
  - How to balance research ideas with production demands?
  - Software building blocks
- Can tools adhere to “conceptual models” ?
  - **Tools and services should identify “what” they are implementing.**

## Pilot Abstraction: Schematic

---

A system that generalizes a placeholder job to allow application-level control of acquired resources via a scheduling overlay.

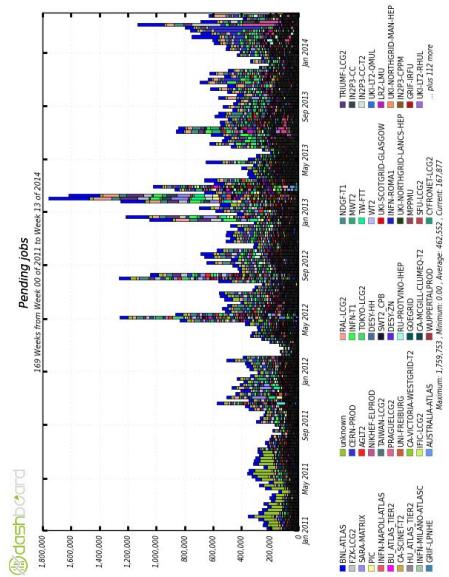

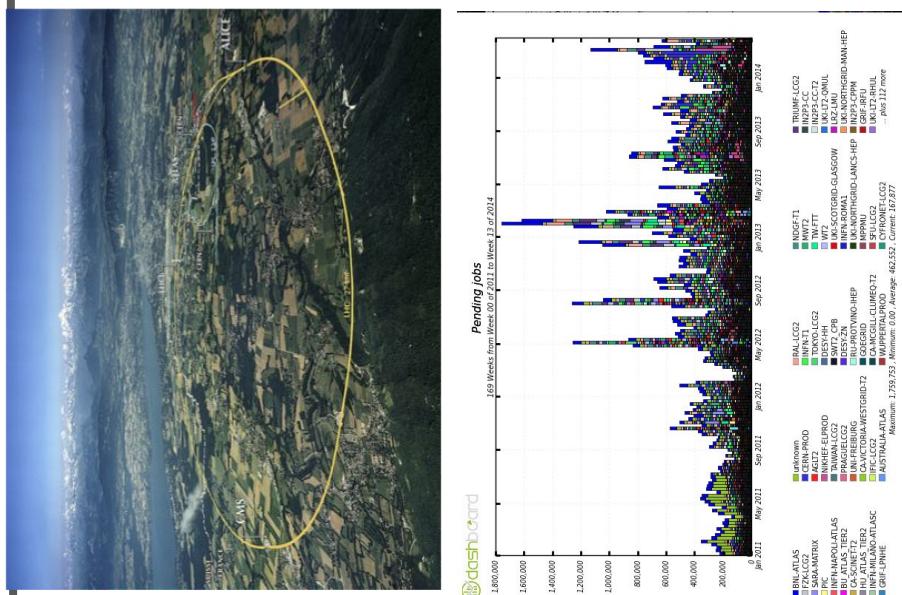

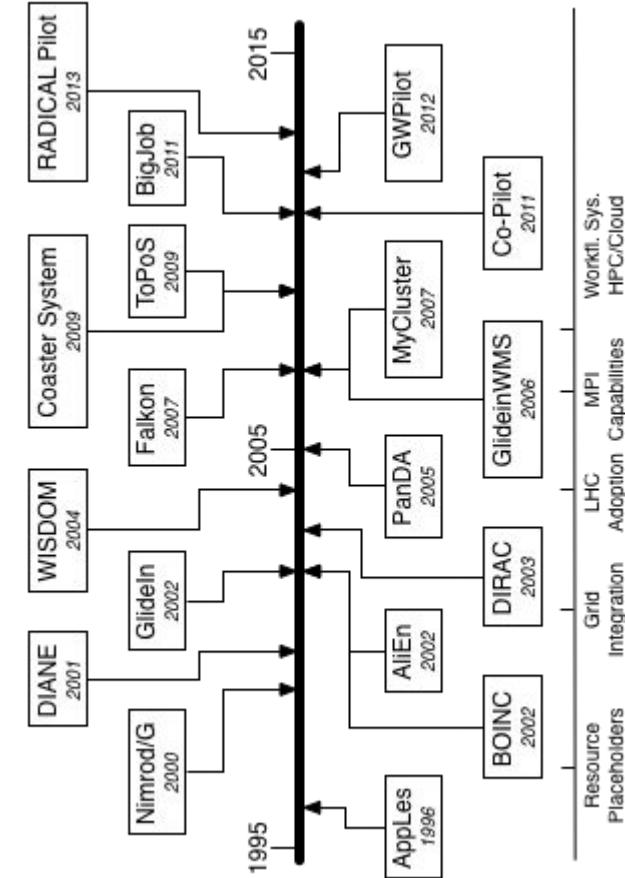

# Pilot Abstraction: Overview

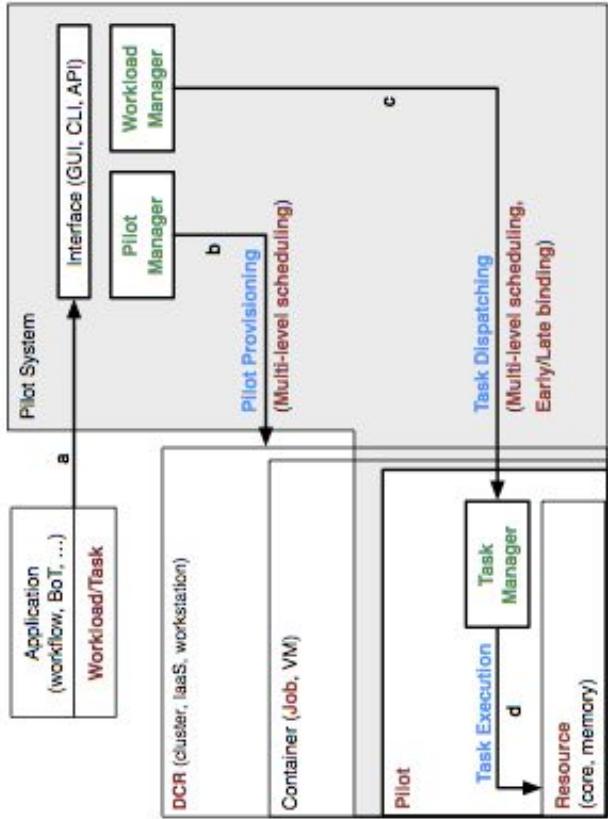

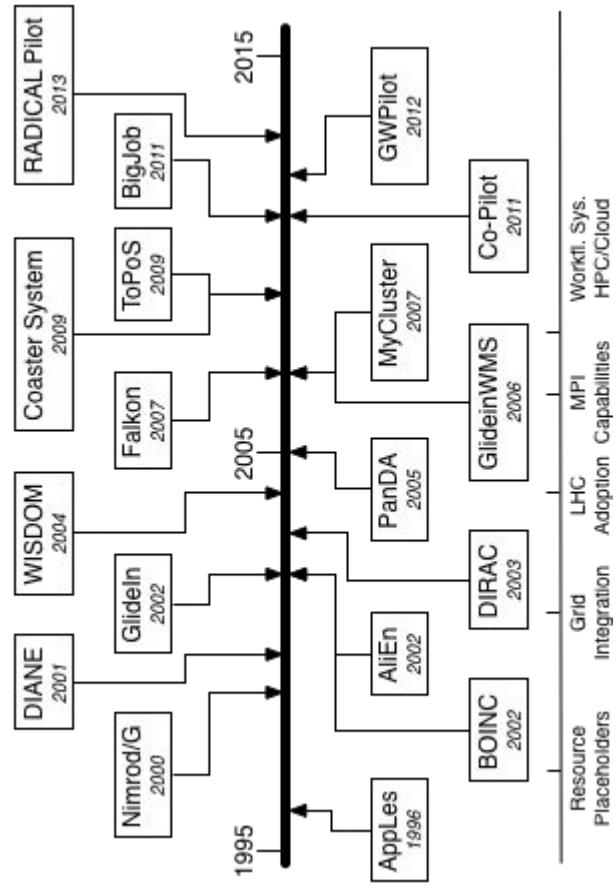

---

- Working definition:
  - “.. defined as an abstraction that generalizes the reoccurring concept of utilizing a placeholder job as a container for a set of compute tasks”
- Advantages of Pilot-Abstractions:
  - Decouples workload from resource management
  - Flexible Resource Management
    - Enables the fine-grained (ie “slicing and dicing”) of resources
    - Tighter temporal control and other advantages of application-level Scheduling (avoid limitations of system-level only scheduling)
  - Build higher-level frameworks without explicit resource management

# Pilot Jobs: Many Variations on a Theme

# P\* Model for Pilot Abstraction: Conceptual Model

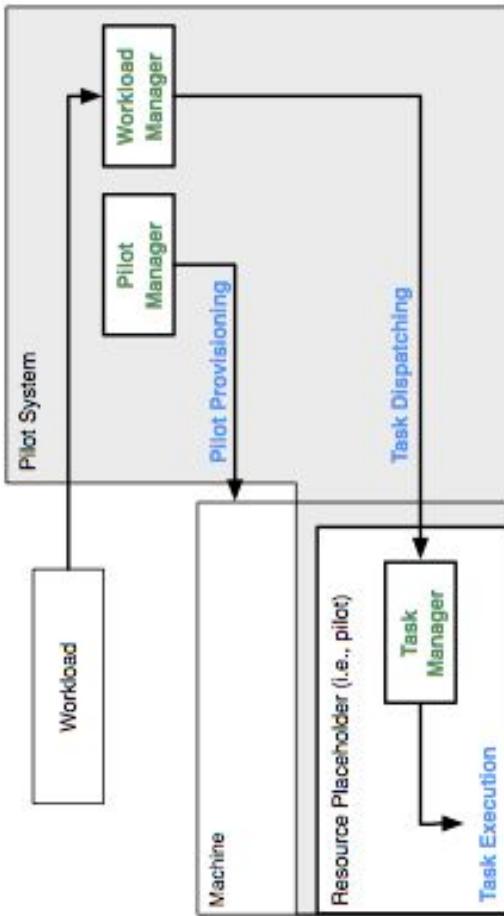

- **P\* Model of Pilot-Jobs**
  - “P\*: A Model of Pilot-Abstractions”, 8th IEEE International Conference on e-Science 2012
  - *A Comprehensive Perspective on Pilot-Jobs* <http://arxiv.org/abs/1508.04180> (2015)

# Pilot Abstraction: Logical components and functionality

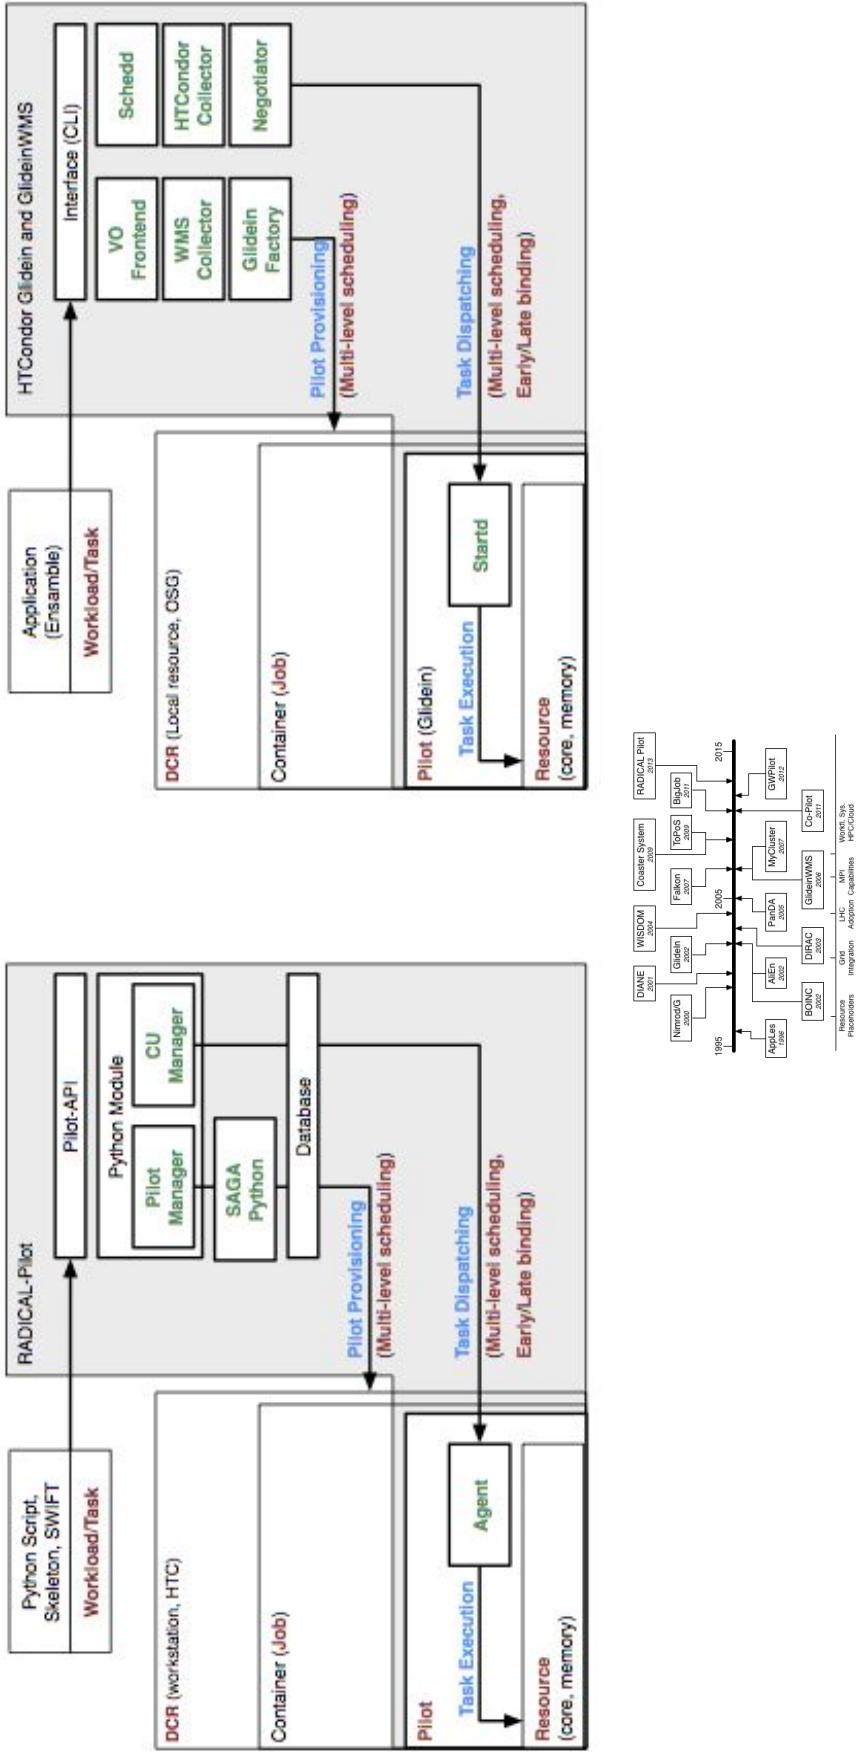

---

- Necessary Logical components:
  - Pilot Manager
  - Workload Manager
  - Task Executor/Manager
- Necessary functions:
  - Pilot provisioning
  - Task dispatching
  - Task execution

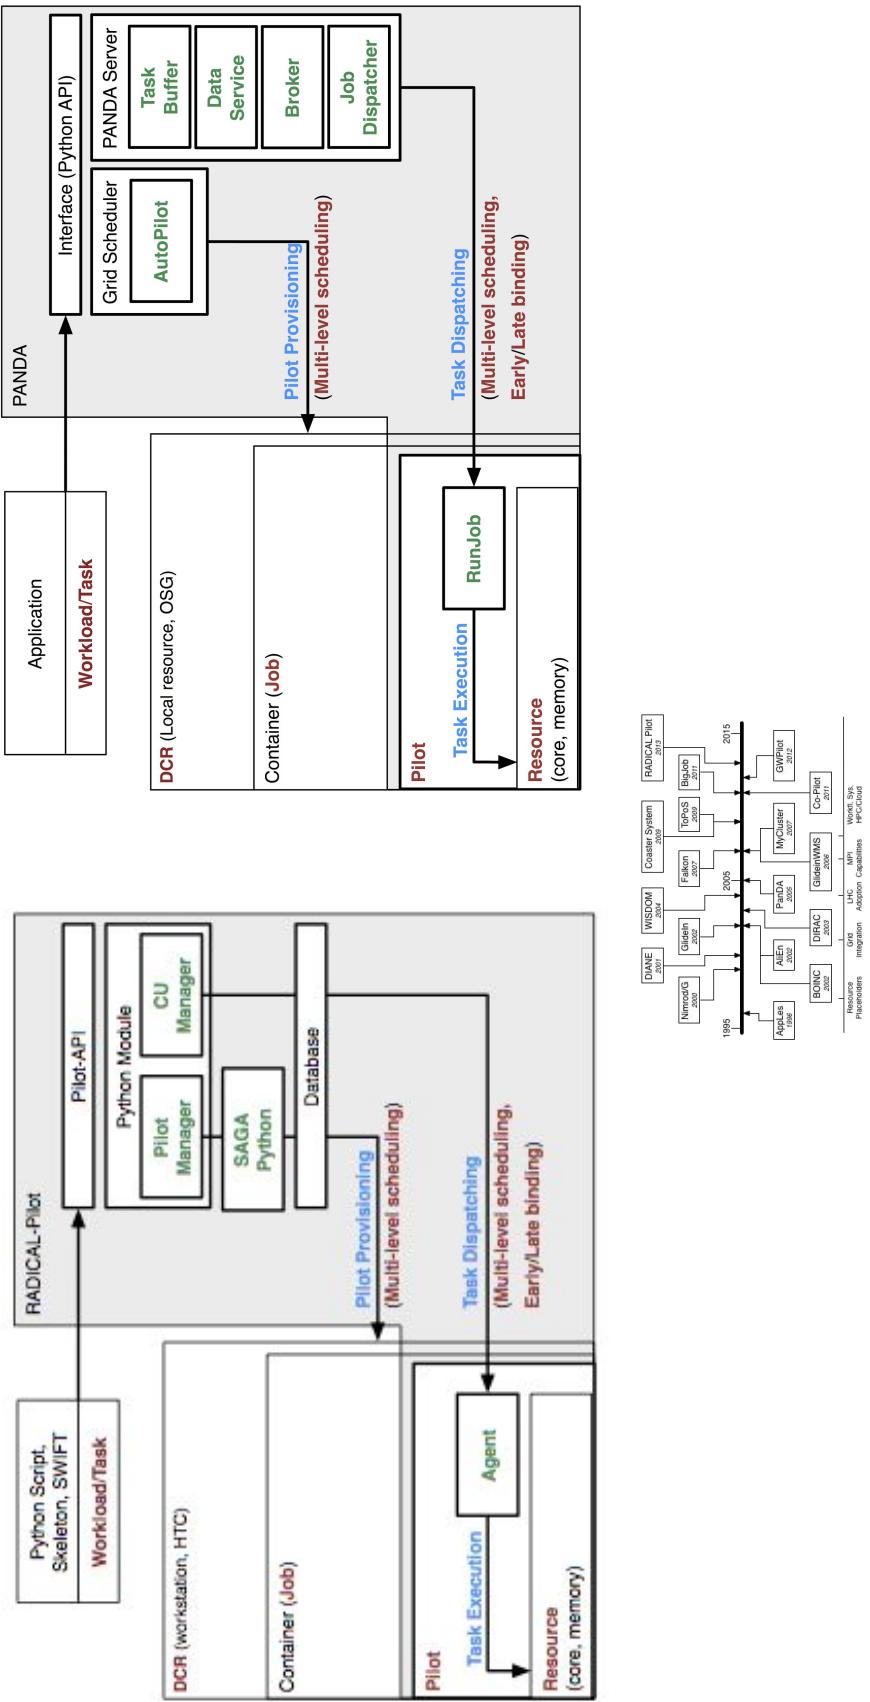

Diagrammatic representation of logical components capabilities.

# Common Components, Functionality and Vocabulary

# Common Components, Functionality and Vocabulary

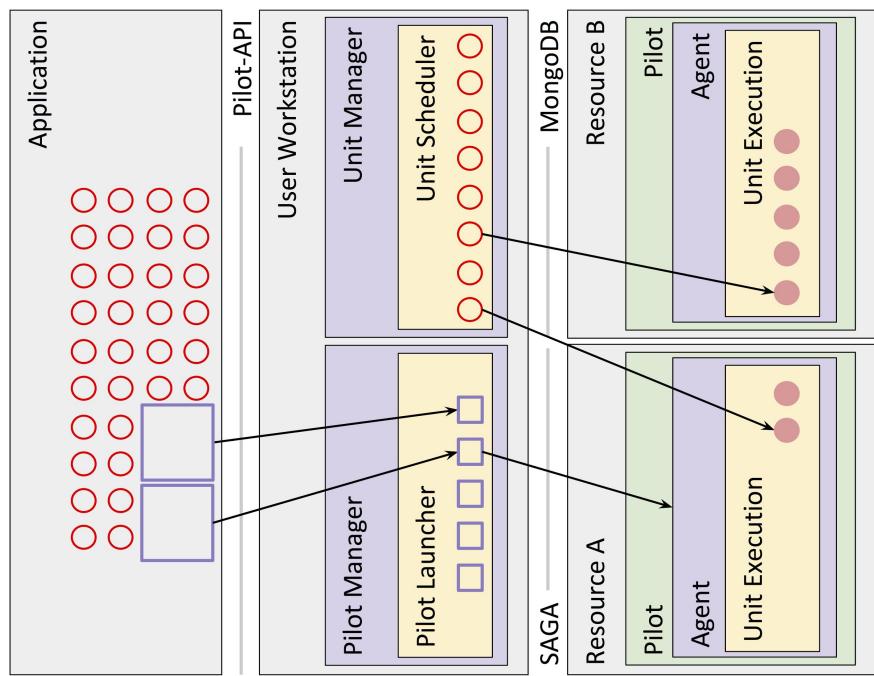

# HPC Requirements / Goals

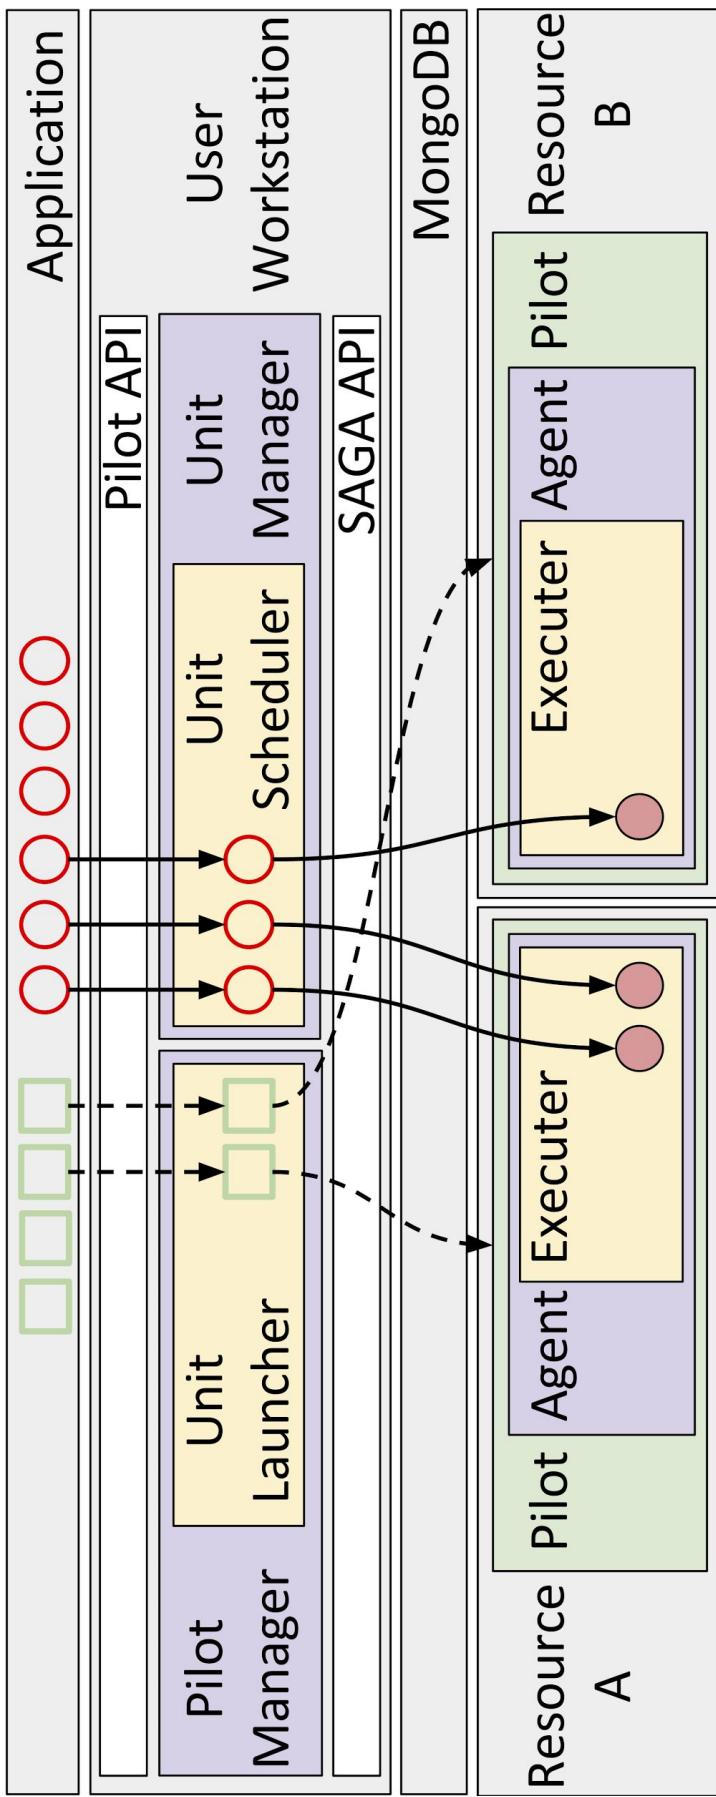

---

- Workload with *heterogeneous* tasks
  - Varying core count
  - Varying application kernels
  - MPI / non-MPI
- Dynamic workload with workload unknown *a priori*
  - Dynamic: Tasks (workload) and task relations
- Control over concurrency of tasks
  - Might be loosely coupled (e.g. replica exchange)
- Multiple dimensions of scalability
  - $O(100k)$  concurrent tasks

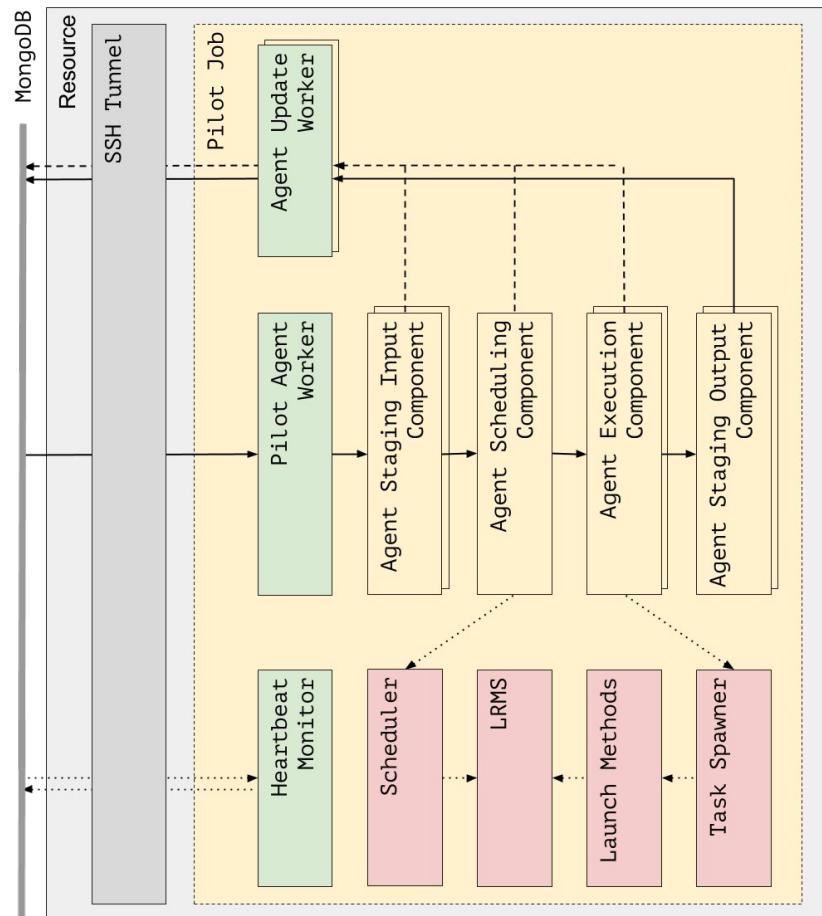

# RADICAL-Pilot Architecture

## RADICAL-Pilot Architecture (2)

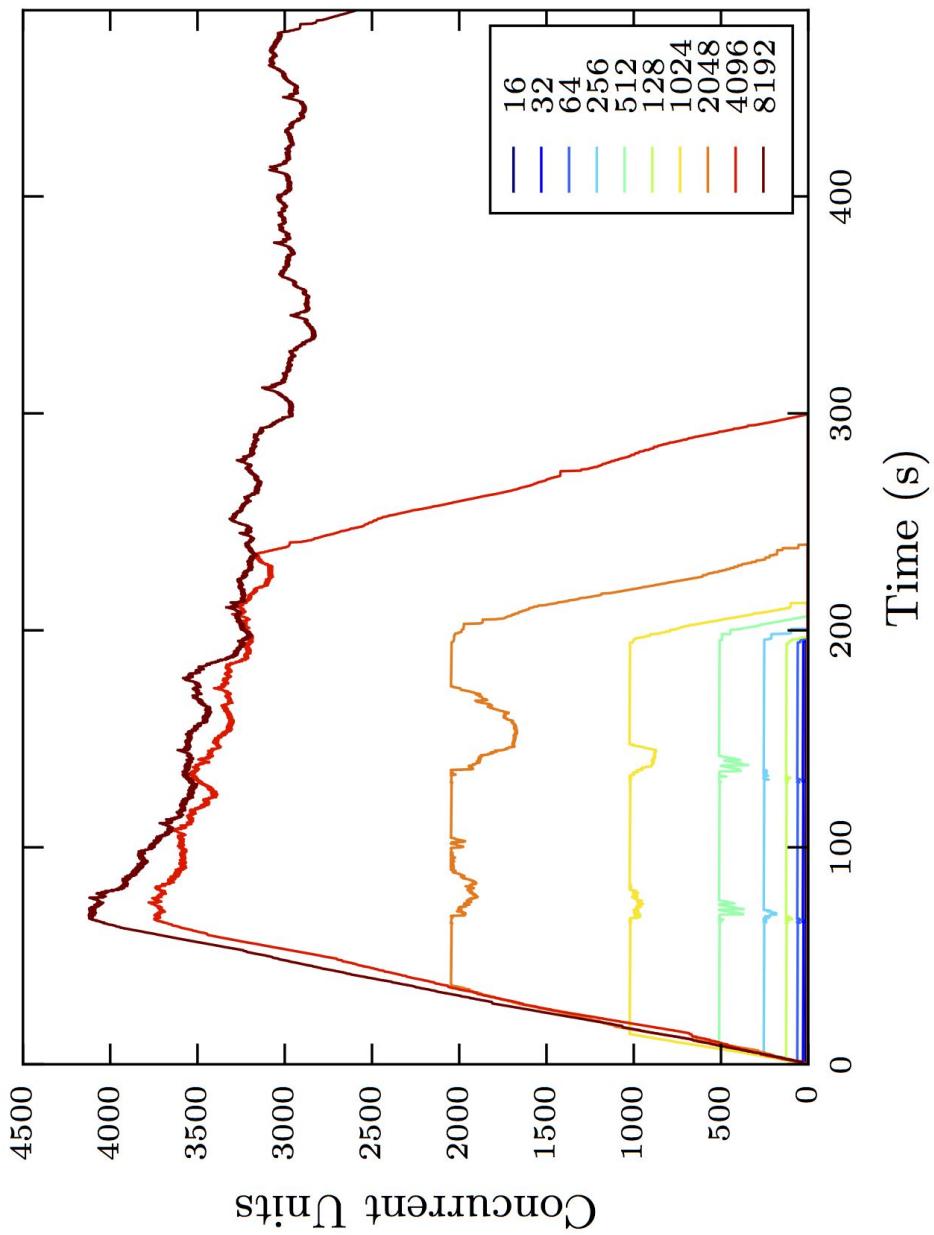

# Agent Architecture

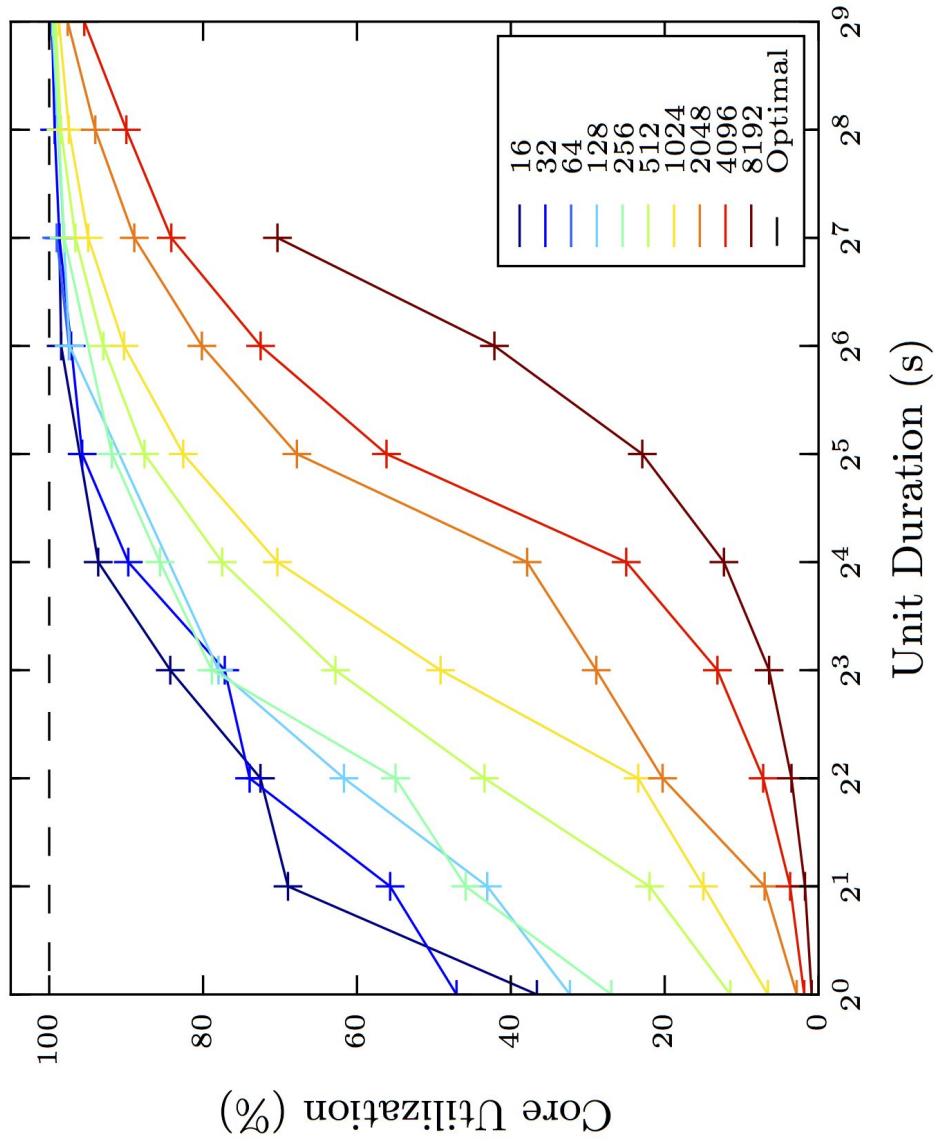

# Agent Performance: Concurrent Units

---

# Agent Performance: Resource Utilization

# Challenges of O(100K) Concurrent Tasks

---

- Agent communication layer (ZMQ) has limited throughput
  - limit is not yet reached
  - bulk messages (is implemented now)
  - separate message channels
  - code optimization
- Agent scheduler (node placement) does not scale well with number of cores
  - bulk operations (schedule bag of tasks at once)
  - good scheduling algorithms and implementations exist
  - code optimization
- Collecting complete jobs is just as hard as spawning new ones
  - decouple
- Interaction with DB and client side has limited scalability
  - replace with proper messaging protocol (also ZMQ?)

# So why is it a challenge...

---

... to build “Scalable, Extensible and Flexible” tools?

- Every high-performance computing system/supercomputing environment is different, if not unique:
  - **Interoperability** across distinct interfaces and semantics: Batch queue systems, data access/movement etc.
  - **Portability:** Software environments, Simulation Kernel, Python, compilers, libraries, etc.
- Generality is often orthogonal to performance:
  - **Extensibility + Flexibility:** You can either make it general-purpose or high-performant.
  - **Reality:** find the sweet spot between general-purpose and performance
