Motivation

Motivation:WEP

- General relativity is a classical (non quantum) theory;
- EEP violations may appear in some quantum theory
- New quantum scalar and vector fields are allowed in some models (Kaluza Klein)

Einstein field: tensor graviton (Spin 2, "Newtonian")

- + Gravi-vector (spin 1)
- + Gravi-scalar (spin 0)

These fields may mediate interactions violating the equivalence principle

Discussion and experimental constraintsM, Nieto and T. Goldman, Phys. Rep. 205 (1991) 221Motivation for antigravity in General RelativityG. Chardin, Hyperfine Interactions 109 (1997) 83

Scalar: "charge" of particle equal to "charge of antiparticle" : attractive force Vector: "charge" of particle opposite to "charge of antiparticle": repulsive/attractive force

$$V = -\frac{G_{\infty}}{r} m_1 m_2 (1 \mp a e^{-r/v} + b e^{-r/s}) \qquad \text{Phys. Rev. D 33 (2475) (1986)}$$

Cancellation effects in matter experiment if a \approx b and v \approx s

AEgIS: Antihydrogen Experiment: Gravity, Interferometry, Spectroscopy

Tests of gravity require very cold trapped \overline{H} or a pulsed cold beam of \overline{H}

 $G \sim 100 nV/m \text{ on } \overline{p}$

Experimental goal: g measurement with 1% accuracy on antihydrogen

(first direct measurement on antimatter)

a) production of a pulsed cold beam of antihydrogen (T~0.1K)

b) measurement of the beam deflection with a Moiré deflectometer

Schematic: i) antihydrogen formation

• Charge exchange reaction:

$$Ps^* + \overline{p} \rightarrow \overline{H}^* + e^-$$

Works well at temperatures from 0–10 K

- Principle demonstrated by ATRAP (Cs* → Ps* → H*)
 [C. H. Storry *et al.*, Phys. Rev. Lett. **93** (2004) 263401]
- Advantages:
- Large cross-section $\sigma = a_0 n^4$
- Narrow and well-defined H
 n-state distribution
- H
 production from p
 at rest

 → ultracold H

At T(p) = 100 mK, n(Ps) = 35 $\Rightarrow v(\text{H}) \approx 45 \text{ m/s}$ $T(\text{H}) \approx 120 \text{mK}$

Schematic: ii) beam formation

- Neutral atoms are not sensitive to static electric and magnetic fields
- Electric field gradients exert force on electric dipoles:

$$E = -\frac{1}{2n^2} + \frac{3}{2}nkF$$

$$Force = -\frac{3}{2}nk\vec{\nabla}F$$

⇒Rydberg atoms are very sensitive to inhomogeneous electric fields

• Stark deceleration of hydrogen demonstrated [E. Vliegen & F. Merkt, J. Phys. B **39** (2006) L241 - ETH Physical Chemistry]

Lectures on Antimatter

- n = 22,23,24
- Accelerations of up to 2×10^8 m/s² achieved
- Hydrogen beam at 700 m/s can be stopped in 5 µs over only 1.8 mm

Schematic: iii) trajectory measurement

- Classical counterpart of the Mach-Zehnder interferometer
- Decoherence effects reduced
- "Self-focusing" effect beam collimation uncritical

- Replace the third grating and detector by position-sensitive detector
 - \Rightarrow Transmission increases by ~ factor 3
- Has been successfully used for a gravity measurement with ordinary matter, σ(g)/g = 2×10⁻⁴
 [M. K. Oberthaler *et al.*, Phys. Rev. A 54 (1996) 3165]

The AD-4 Experiment at CERN

INGREDIENTS:

- V-79 Chinese Hamster cells embedded in gelatin
- Antiproton beam from AD (126 MeV)

METHOD:

- Irradiate cells with dose levels to give survival in the peak is between 0 and 90 %
- Slice samples, dissolve gel, incubate cells, and look for number of colonies

ANALYSIS:

Study cell survival in peak (tumor) and plateau (skin) and compare the results to protons (and carbon ions)

Example: Protons at TRIUMF

Antiproton – Proton Comparison

Protons

Lectures on Antimatter

Potential Clinical Advantages?

Each Particle Type shows distinct features

- Protons are well known and easy to plan (RBE = 1) which is the reason they are most widely adopted.
- Antiprotons have lowest entrance dose for the price of an extended isotropic low dose halo.
- Carbon ions have sharpest lateral penumbra but comparatively higher entrance dose than even protons (no RBE included here), but show forward directed tail due to in beam fragmentation.

Detailed dose plans (<u>including RBE</u>) will need to be developed to assess applicability of particle types for different tumor types and locations!

DNA Damage Assays

There is more to biology than just clonogenics – especially outside the targeted area:

- > Immediately after attack on DNA proteins are recruited to the site
- > This event signals cell cycle arrest to allow repair
- > If damage is too extensive to repair programmed cell death (apoptosis) is induced
- Cells also deficient of cell cycle check point proteins may enter mitosis (cancer cells are often deficient in repair proteins and continue dividing)
 - γ-H2AX: Phosphorylation of H2AX in the presence of Double Strand Breaks

Micronuclei: Fluorescent detection of micronuclei (parts of whole chromosomes) formed due to DNA damage indicating potential of tumorigenesis

 γ -H2AX and Micronucleus assays are typically used to study immediate and long term DNA damage respectively

Lectures on Antimatter

You are an antimatter factory

Your body produces antimatter:

The body of an 80 kg individual produces 180 positrons per hour! These come from the disintegration of potassium-40, a natural isotope which is absorbed by drinking water, eating (bananas!) and breathing.
