CERN Academic Training Course

Nov 2016

Least squares best fit

What is σ ?

Resume of straight line

Correlated errors

Goodness of fit with χ^2

Number of Degrees of Freedom

Other G of F methods

Errors of first and second kind

Combinations

THE paradox

Least Squares Straight Line Fitting

Data = $\{x_i, y_i \pm \delta y_i\}$

1) Does it fit straight line?

(Goodness of Fit)

2) What are gradient and intercept?

(Parameter Determination)

Do 2) first

N.B.1 Can be used for non “ $a+bx$ ”

e.g. $a + b/x + c/x^2$

N.B.2 Least squares is not the only method

Criterion:

$$S = \sum_i \left(\frac{y_i^{\text{th}}(a, b) - y_i^{\text{obs}}}{\sigma_i} \right)^2$$

$a + bx_i$ (points to the theoretical value in the numerator)
 Vert devn (points to the entire fraction in the numerator)
 σ_i (points to the denominator)
 An error for each pt. (points to the denominator)

If theory and data OK:
 $y^{\text{th}} \sim y^{\text{obs}} \rightarrow S$ small
 Minimise $S \rightarrow$ best line
 Value of $S_{\text{min}} \rightarrow$ how good
 fit is

Which σ should we use?

Which σ ?

Exptl σ

Theory σ

Name

Neyman

Pearson

Ease of algebra

Easier, so this version
is used more

If Th = 0.01, Exp = 1

Contributes 1 to S

Contributes 98 to S
More plausible

$S \sim \chi^2$?

More plausible

$$S = (\hat{a} - a_1)^2 / \sigma^2 + (\hat{a} - a_2)^2 / \sigma^2$$

Biassed down because
smaller $a_i \rightarrow$ smaller σ

Biassed up because
larger $\hat{a} \rightarrow$ larger σ

(For $\hat{a} \sim a_i$, and both much larger than σ_i , 2 methods are very similar)

Straight Line Fit

$$S = \sum_i \left(\frac{(a + bx_i) - y_i}{\sigma_i} \right)^2 \quad (\text{Fixed } \sigma_i)$$

i) "Draw" lots of lines \Rightarrow S for each

ii) Minimise S (w.r.t. a + b)

$$\begin{aligned} \frac{1}{2} \frac{\partial S}{\partial a} &= \sum_i \frac{(a + bx_i - y_i)}{\sigma_i^2} = 0 \\ \frac{1}{2} \frac{\partial S}{\partial b} &= \sum_i \frac{(a + bx_i - y_i)x_i}{\sigma_i^2} = 0 \end{aligned} \quad \left. \begin{array}{l} \text{2} \\ \text{SIM. EQNS} \\ \text{FOR 2} \\ \text{UNKNOWN} \\ \text{(\underline{a} + \underline{b})} \end{array} \right\}$$

$$b = \frac{[1][xy] - [x][y]}{[1][x^2] - [x][x]} = \frac{\langle xy \rangle - \langle x \rangle \langle y \rangle}{\langle x^2 \rangle - \langle x \rangle^2}$$

$$\text{where } [f] = \sum \frac{f_i}{\sigma_i^2}$$

$$\text{or } \langle f \rangle = [f]/[1]$$

$$\langle y \rangle = a + b \langle x \rangle \quad \Rightarrow \quad a$$

N.B. L.S.B.F. passes through $(\langle x \rangle, \langle y \rangle)$

Correlated intercept and gradient?

2 * Inverse covariance matrix =

$$\begin{bmatrix} \frac{\partial^2 S}{\partial a^2} & \frac{\partial^2 S}{\partial a \partial b} \\ \frac{\partial^2 S}{\partial a \partial b} & \frac{\partial^2 S}{\partial b^2} \end{bmatrix} = \begin{bmatrix} \Sigma 1/\sigma_i^2 & \Sigma x_i/\sigma_i^2 \\ \Sigma x_i/\sigma_i^2 & \Sigma x_i^2/\sigma_i^2 \end{bmatrix}$$

Invert → **Covariance matrix**

Covariance $\sim -\Sigma x_i/\sigma_i^2 = [x]$

If measure intercept at weighted c. of g. of x for data points, **cov = 0**

i.e. gradient and intercept there are **uncorrelated**

So track params are usually specified at centre of track.

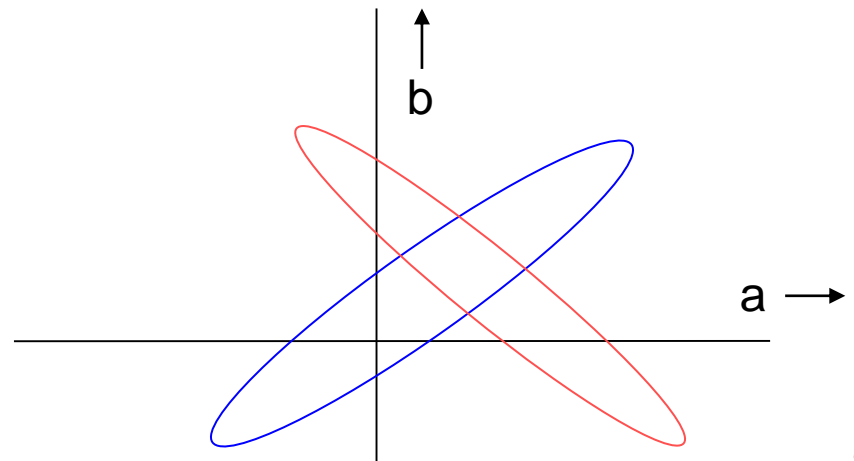

Covariance(a,b) ~ $-\langle x \rangle$

$\langle x \rangle$ positive

$\langle x \rangle$ negative

Measurements with correlated errors e.g. systematics?

Start with 2 uncorrelated measurements

$$S = \frac{(p - p_{pr})^2}{\sigma_1^2} + \frac{(q - q_{pr})^2}{\sigma_2^2} \quad \#$$

Introduce correlations by

$$\begin{aligned} p &= r \cos \theta - s \sin \theta \\ q &= r \sin \theta + s \cos \theta \end{aligned}$$

NOT ROTN
in x-y SPACE

Write σ_p σ_q (+ $\text{cov}(p, q) = 0$) in terms of σ_r^2 σ_s^2 + $\text{cov}(r, s)$

$$\Rightarrow S = \frac{1}{\sigma_r^2 \sigma_s^2 - \text{cov}(r, s)} \left[\sigma_s^2 (r - r_{pr})^2 + \sigma_r^2 (s - s_{pr})^2 - 2 \text{cov}(r, s) (r - r_{pr})(s - s_{pr}) \right]$$

Inv. est
matrix
element

$$= H_{11} (r - r_{pr})^2 + H_{22} (s - s_{pr})^2 + 2 H_{12} (r - r_{pr})(s - s_{pr})$$

$$\text{where } H^{-1} = \begin{pmatrix} \sigma_r^2 & \text{cov} \\ \text{cov} & \sigma_s^2 \end{pmatrix} \leftarrow \text{ERROR matrix}$$

Reduces to standard formula in absence of correlus

$$\text{In general: } S = \sum_{ij} \tilde{\Delta}_i H_{ij} \Delta_j$$

where $\Delta_j = (\text{observed} - \text{pred.})_j$

Comments on Least Squares method

1) Need to bin

Beware of too few events/bin

2) Extends to n dimensions

but needs lots of events for n larger than 2 or 3

3) No problem with correlated uncertainties

4) Can calculate S_{\min} “on line” i.e. single pass through data

$$\Sigma (y_i - a - bx_i)^2 / \sigma^2 = [y_i^2] - b [x_i y_i] - a [y_i]$$

5) For theory linear in params, analytic solution

6) Goodness of Fit

	Individual events (e.g. in $\cos \theta$)	$y_i \pm \sigma_i$ v x_i (e.g. stars)
1) Need to bin?	Yes	No need
4) χ^2 on line	First histogram	Yes

	Moments	Max Like	Least squares
Easy?	Yes, if...	Normalisation, maximisation messy	Minimisation
Efficient?	Not very	Usually best	Sometimes = Max Like
Input	Separate events	Separate events	Histogram
Goodness of fit	Messy	No (unbinned)	Easy
Constraints	No	Yes	Yes
N dimensions	Easy if	Norm, max messier	Easy
Weighted events	Easy	Errors difficult	Easy
Bgd subtraction	Easy	Troublesome	Easy
Inverse covariance matrix	Observed spread, or analytic	$\left\{ \frac{-\partial^2 \ln \mathcal{L}}{\partial p_i \partial p_j} \right\}$	$\left\{ \frac{\partial^2 S}{2 \partial p_i \partial p_j} \right\}$
Main feature	Easy	Best	Goodness of Fit

Goodness of Fit: χ^2 test

1) Construct S and minimise wrt free parameters

2) Determine $\nu = \text{no. of degrees of freedom}$

$$\nu = n - p$$

$n = \text{no. of data points}$

$p = \text{no. of FREE parameters}$

3) Look up probability that, for ν degrees of freedom, $\chi^2 \geq S_{\min}$

Uses i) Poisson \sim Gaussian if expected number not too small

ii) For N y_i distributed as Gaussian $N(0,1)$, $\sum y_i^2 \sim \chi^2$ with $\text{ndf} = N$

So works ASYMPTOTICALLY. Otherwise use MC for dist of S (or binned \mathcal{L})

Properties of mathematical χ^2 distribution:

$$\overline{\chi^2} = v$$
$$\sigma^2(\chi^2) = 2v$$

Fig. 2.6

So $S_{\min} > v + 3\sqrt{2v}$ is **LARGE**

e.g. $S_{\min} = 2200$ for $v = 2000$?

Cf: Area in tails of Gaussian

χ^2 with ν degrees of freedom?

$\nu = \text{data} - \text{free parameters} ?$

Why asymptotic (apart from Poisson \rightarrow Gaussian) ?

a) Fit flatish histogram with

$$y = N \{ 1 + 10^{-6} \cos(x - x_0) \} \quad x_0 = \text{free param}$$

b) Neutrino oscillations: almost degenerate parameters

$$\begin{array}{ll} y \sim 1 - A \sin^2(1.27 \Delta m^2 L/E) & 2 \text{ parameters} \\ \xrightarrow{\text{Small } \Delta m^2} 1 - A (1.27 \Delta m^2 L/E)^2 & 1 \text{ parameter} \end{array}$$

Goodness of Fit

- χ^2 Very general
Needs binning
Not sensitive to sign of deviation

Run Test

Kolmogorov-Smirnov

Aslan and Zech 'Energy Test'
Durham IPPP Stats Conf (2002)

Binned Likelihood (= Baker-Cousins)

etc

Goodness of Fit: Kolmogorov-Smirnov

Compares data and model cumulative plots
(or 2 sets of data)

Uses largest discrepancy between dists.

Model can be analytic or MC sample

Uses individual data points

Not so sensitive to deviations in tails

(so variants of K-S exist)

Not readily extendible to more dimensions

Distribution-free conversion to p ; depends on n

(but not when free parameters involved – needs MC)

Goodness of fit: 'Energy' test

Assign +ve charge to data \star ; -ve charge to M.C. \star

Calculate 'electrostatic energy E' of charges

If distributions agree, $E \sim 0$

If distributions don't overlap, E is positive

Assess significance of magnitude of E by MC

N.B.

- 1) Works in many dimensions
- 2) Needs metric for each variable (make variances similar?)
- 3) $E \sim \sum q_i q_j f(\Delta r = |r_i - r_j|)$, $f = 1/(\Delta r + \epsilon)$ or $-\ln(\Delta r + \epsilon)$

Performance insensitive to choice of small ϵ

See [Aslan and Zech's](#) paper at:

<http://www.ippp.dur.ac.uk/Workshops/02/statistics/program.shtml>

Binned data and Goodness of Fit using \mathcal{L} -ratio

For histogram, uses Poisson prob $P(n;\mu)$ for n observed events when expect μ .

Construct \mathcal{L} -ratio = $\text{Product}\{P(n_i;\mu_i)/P(n_i;\mu=n_i)\}$
 $P(n_i;\mu=n_i)$ is best possible μ for that n_i
Need denoms because $P(100;100.0)$
very different from $P(1;1.0)$

$-2 * \mathcal{L}$ ratio $\sim \chi^2$ when μ_i large and $n_i \sim \mu_i$

Better than Neyman or Pearson χ^2 when μ_i small

Baker and Cousins, NIM 221 (1984) 437

Wrong Decisions

Error of First Kind

Reject H_0 when true

Should happen x% of tests

Errors of Second Kind

Accept H_0 when something else is true

Frequency depends on

i) How similar other hypotheses are

e.g. $H_0 = \mu$

Alternatives are: e π K p

ii) Relative frequencies: 10^{-4} 10^{-4} 1 0.1 0.1

Aim for maximum efficiency ← Low error of 1st kind

maximum purity ← Low error of 2nd kind

As χ^2 cut tightens, efficiency ↑ and purity ↓

Choose compromise

How serious are errors of 1st and 2nd kind?

1) Result of experiment

e.g Is spin of resonance = 2?

Get answer WRONG

Where to set cut?

Small cut \Rightarrow Reject when correct

Large cut \Rightarrow Never reject anything

Depends on nature of H0 e.g.

Does answer agree with previous expt?

Is expt consistent with special relativity?

2) Class selector e.g. b-quark / galaxy type / γ -induced cosmic shower

Error of 1st kind: Loss of efficiency

Error of 2nd kind: More background

Usually easier to allow for 1st than for 2nd

3) Track finding

Combining: Uncorrelated exptl results

Simple Example of Minimising S

Measurements $a_1 \pm \sigma_1$
 $a_2 \pm \sigma_2$
 \vdots
 $a_i \pm \sigma_i$ } Best value $\hat{a} \pm \sigma$

Construct $S = \sum \left(\frac{\hat{a} - a_i}{\sigma_i} \right)^2$

Minimise S w.r.t. \hat{a}

$$\frac{1}{2} \frac{\partial S}{\partial \hat{a}} = \sum \frac{\hat{a} - a_i}{\sigma_i^2} = 0$$

$$\hat{a} \sum \frac{1}{\sigma_i^2} = \sum \frac{a_i}{\sigma_i^2} \quad \star$$

Error on \hat{a} given by $\sigma = \left(\frac{1}{2} \frac{\partial^2 S}{\partial \hat{a}^2} \right)^{-1/2}$

$$\frac{\partial^2 S}{\partial \hat{a}^2} = 2 \sum \frac{1}{\sigma_i^2}$$

$$\therefore \frac{1}{\sigma^2} = \sum \frac{1}{\sigma_i^2} \quad \star$$

IN PARABOLIC APX
EQUIV TO
 $S \rightarrow S_{\min} + 1$

Many params

$$\frac{1}{2} \frac{\partial^2 S}{\partial x_i \partial x_j} = \text{INVERSE ERROR MATRIX}$$

N.B. Better to combine data rather than results

So $\hat{a} = \sum w_i a_i / \sum w_i$, where $w_i = 1/\sigma_i^2$

Difference between weighted and simple averaging

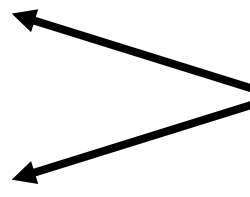

Isolated island with conservative inhabitants
How many married people ?

Number of married men = 100 ± 5 K

Number of married women = 80 ± 30 K

Total = 180 ± 30 K
Wtd average = 99 ± 5 K
→ Total = 198 ± 10 K

CONTRAST

GENERAL POINT: Adding (uncontroversial) theoretical input can improve precision of answer
Compare “kinematic fitting”

BLUE

Best Linear Unbiased Estimate

Combine several possibly correlated estimates of same quantity

e.g. v_1, v_2, v_3

Covariance matrix

$$\begin{bmatrix} \sigma_1^2 & \text{COV}_{12} & \text{COV}_{13} \\ \text{COV}_{12} & \sigma_2^2 & \text{COV}_{23} \\ \text{COV}_{13} & \text{COV}_{23} & \sigma_3^2 \end{bmatrix}$$

Uncorrelated

Positive correlation

Negative correlation

$$\text{cov}_{ij} = \rho_{ij} \sigma_i \sigma_j \quad \text{with} \quad -1 \leq \rho \leq 1$$

Lyons, Gibault + Clifford
NIM A270 (1988) 42

$$V_{\text{best}} = w_1 v_1 + w_2 v_2 + w_3 v_3$$

$$\text{with } w_1 + w_2 + w_3 = 1$$

$$\text{to give } \sigma_{\text{best}} = \min (\text{wrt } w_1, w_2, w_3)$$

For uncorrelated case, $w_i \sim 1/\sigma_i^2$

For correlated pair of measurements with $\sigma_1 < \sigma_2$

$$v_{\text{best}} = \alpha v_1 + \beta v_2 \quad \beta = 1 - \alpha$$

$$\beta = 0 \text{ for } \rho = \sigma_1/\sigma_2$$

$$\beta < 0 \text{ for } \rho > \sigma_1/\sigma_2 \text{ i.e. extrapolation!} \quad \text{e.g. } v_{\text{best}} = 2v_1 - v_2$$

Linear

Unbiased

Best

Extrapolation is sensible:

Beware extrapolations because

[b] σ_{best} tends to zero, for $\rho = +1$ or -1

[a] v_{best} sensitive to ρ and σ_1/σ_2

N.B. For different analyses of ~ same data,
 $\rho \sim 1$, so choose 'better' analysis, rather than
 combining

N.B. σ_{best} depends on σ_1 , σ_2 and ρ , but not on $v_1 - v_2$
e.g. Combining 0 ± 3 and $x \pm 3$ gives $x/2 \pm 2$

$$\text{BLUE} = \chi^2$$

$S(v_{\text{best}}) = \sum (v_i - v_{\text{best}}) E^{-1}_{ij} (v_j - v_{\text{best}})$, and minimise S wrt v_{best}

S_{min} distributed like χ^2 , so measures Goodness of Fit

But **BLUE** gives weights for each v_i

Can be used to see contributions to σ_{best} from each source of uncertainties e.g. statistical and systematics

different systematics

For combining two or more possibly correlated measured quantities {e.g. intercepts and gradients of a straight line), use χ^2 approach.

Alternatively. Valassi has extended **BLUE** approach

Covariance(a,b) ~ $-\langle x \rangle$

$\langle x \rangle$ positive

$\langle x \rangle$ negative

Uncertainty on $\Omega_{\text{dark energy}}$

When combining pairs of variables, the uncertainties on the **combined parameters** can be **much** smaller than any of **the individual** uncertainties
e.g. $\Omega_{\text{dark energy}}$

THE PARADOX

Histogram with 100 bins

Fit with 1 parameter

S_{\min} : χ^2 with NDF = 99 (Expected $\chi^2 = 99 \pm 14$)

For our data, $S_{\min}(p_0) = 90$

Is p_2 acceptable if $S(p_2) = 115$?

1) YES. Very acceptable χ^2 probability

2) NO. σ_p from $S(p_0 + \sigma_p) = S_{\min} + 1 = 91$

But $S(p_2) - S(p_0) = 25$

So p_2 is 5σ away from best value

Best estimate
of β

Is this value
of β acceptable?

NDF = 99

Bayes and Frequentism: the return of an old controversy

The ideologies, with examples

Upper limits

Feldman and Cousins

Summary

KINEMATIC FITTING

Tests whether observed event is consistent with specified reaction

$$\bar{p}p \rightarrow \bar{p}p \pi^+ \pi^- ?$$

$$e^+e^- \rightarrow W^+W^- \rightarrow j_1 j_2 j_3 j_4$$

M_W , jet pairings

$$e^+e^- \rightarrow W^+W^- \rightarrow \mu \nu$$

$j_1 j_2$

$$\Lambda \rightarrow p \pi^- \text{ from prodn vertex}$$

$$p + \pi^- \text{ interact}$$

$$\Lambda \rightarrow p \pi^- \text{ from prodn vert.}$$

Kinematic Fitting: Why do it?

- 1) Check whether event consistent with hypothesis [Goodness of Fit]
- 2) Can calculate missing quantities [Param detn.]
- 3) Good to have tracks conserving E-P [Param detn.]
- 4) Reduces uncertainties [Param detn.]

Kinematic Fitting: Why do it?

1) Check whether event consistent with hypothesis [Goodness of Fit]
Use S_{\min} and ndf

2) Can calculate missing quantities [Param detn.]
e.g. Can obtain $|P|$ for short/straight track, neutral beam; p_x, p_y, p_z of outgoing ν, n, K^0

3) Good to have tracks conserving E-P [Param detn.]
e.g. identical values for resonance mass from prodn or decay

4) Reduces uncertainties [Param detn.]
Example of “Including theoretical input reduces uncertainties”

How we perform Kinematic Fitting ?

Observed event: 4 outgoing charged tracks
Assumed reaction: $pp \rightarrow pp\pi^+\pi^-$

Measured variables: 4-momenta of each track, v_i^{meas}
(i.e. 3-momenta & assumed mass)

Then test hypothesis:

Observed event = example of assumed reaction

i.e. Can tracks be wiggled “a bit” to do so?

Tested by:

$$S_{\min} = \sum (v_i^{\text{fitted}} - v_i^{\text{meas}})^2 / \sigma^2$$

where v_i^{fitted} conserve 4-momenta

(\sum over 4 components of each track)

N.B. Really need to take correlations into account

i.e. Minimisation subject to constraints (involves Lagrange Multipliers)

'KINEMATIC' FITTING

Angles of triangle: $\theta_1 + \theta_2 + \theta_3 = 180$

	θ_1	θ_2	θ_3	
Measured	50	60	73 ± 1	Sum = 183
Fitted	49	59	72	180

$$\chi^2 = (50-49)^2/1^2 + 1 + 1 = 3$$

$$\text{Prob} \{ \chi^2_1 > 3 \} = 8.3\%$$

ALTERNATIVELY:

Sum = 183 ± 1.7 , while expect 180

$$\text{Prob} \{ \text{Gaussian 2-tail area beyond } 1.73\sigma \} = 8.3\%$$

Toy example of Kinematic Fit

+ constraints:

- 1) Coplanar
- 2) p_1 at θ_1
- 3) p_2 at θ_2
- 4) θ_1 or θ_2

Non-relativistic equal mass elastic scatter : $\theta_1 + \theta_2 = \pi/2$

Measured $\theta_1^m \pm \sigma$ $\theta_2^m \pm \sigma$
 Fitted θ_1 θ_2

Minimise $S(\theta_1, \theta_2) = \frac{(\theta_1 - \theta_1^m)^2}{\sigma^2} + \frac{(\theta_2 - \theta_2^m)^2}{\sigma^2}$

subject to $C(\theta_1, \theta_2) = \theta_1 + \theta_2 - \pi/2 = 0$

Lagrange : $\frac{\partial S}{\partial \theta_1} + \lambda \frac{\partial C}{\partial \theta_1} = \frac{\partial S}{\partial \theta_2} + \lambda \frac{\partial C}{\partial \theta_2} = 0$

\Rightarrow 3 eqns for θ_1 , θ_2 , λ

Eqs simple to solve because

$C(\theta_1, \theta_2)$ linear in θ_1, θ_2

$$\rightarrow \theta_1 = \theta_1^m + \frac{1}{2}(\frac{\pi}{2} - \theta_1^m - \theta_2^m)$$

$$\theta_2 = \theta_2^m + \frac{1}{2}(\frac{\pi}{2} - \theta_1^m - \theta_2^m)$$

$$\sigma(\theta_1) = \sigma(\theta_2) = \sigma/\sqrt{2} \quad \star$$

i.e. KINEMATIC FIT \rightarrow
REDUCED UNCERTAINTIES
