Future

Introduction

We study new physics by colliding high energy particles

New particles are produced from the energy released when they collide head on.

If we collide protons the probability (cross section) for this is very small

Not only must the protons collide head on but also their constituent quarks.

We have done this for some time, so if we look for something new, it is a very rare such event.

And if we find it, we want many such events to believe the results

Thus,

- **We must collide a large number of protons each time – use high luminosity proton beams**
- **We must repeat collisions many times – use high collision rates**

Why we need many events

To determine if our **N** new observed events constitute a discovery we must determine if the same data could be produced by combinations of well-known events (e.g. using Monte-Carlo simulations), however unlikely. This is the background **B**.

For **N** to be a discovery $N \gg B$

If **N** is 8 and **B** is 4 then $\sigma(B)$ is 2 (assume Poisson distribution) and **N** is 2σ away i.e. 5% probability that **N** is just random noise

If we measure 4 times as long **N** will be 32, **B** is 16 and $\sigma(B)$ is 4 i.e. 4σ away (0.006% that it is random noise). Much smaller probability that **N** is due to random noise but not enough. 5σ (0.00005% it is random noise) is required for discovery.

If the significance of **N** is less than 5σ it could grow to 5σ after more measurements, but the significance could also decrease or even disappear

One solution to get high luminosity and high repetition rate is to circulate the protons in two ring accelerators that cross in regions where the particles can collide

- **Most protons will pass through and continue to recirculate, but some would collide**
- **Eventually all protons will be lost, but before that they will pass each other many times**

A more practical solution is to group the protons in bunches and let the bunches collide

The Large Hadron Collider

- 27km circumference double ring collider
- 13 TeV (6.5+6.5) – 0.9999999991 times c , i.e. 3m/s less than c
- 4 interaction points with detectors – ATLAS, CMS, LHC-B and ALICE
- 10^{34} protons/cm²/sec focused into 16 μ beams that collide
- 1600 superconducting magnets (up to 9T) to bend and focus the beams
- Bunches with about 10^{11} protons collide every 25 ns
- The total beam energy is 562 MJ – melts 2 ton copper
- Start of operations 2010 (2008)

CROSS SECTION OF LHC DIPOLE

A hierarchical system of accelerators

Lineac 2 → PS Booster → PS → SPS → LHC

50 MeV 1.4 GeV 25 GeV 450 GeV 6.5 TeV

One or two injections into LHC per day

450 GeV injected protons accelerate to 6.5 TeV in 20 minutes

Identifying the collision event

- All short-lived particles decay before entering the detector itself
- Remaining particles: e^- , e^+ , γ , hadrons (p , n ..., jets), μ^+ , μ^- , ν , ?
- A high energy quark will pick up other quarks as it leaves the interaction point, creating a hadron jet
- Onion-like construction with multiple subdetector and magnet shells:
 - Inner detector to find charged particle tracks
 - Magnets to deduce charge and momentum
 - Electromagnetic calorimeter to measure e/g tracks and energy
 - Hadron calorimeter to measure hadron tracks and energy
 - Muon detector to detect muon tracks and momentum

Transverse plane

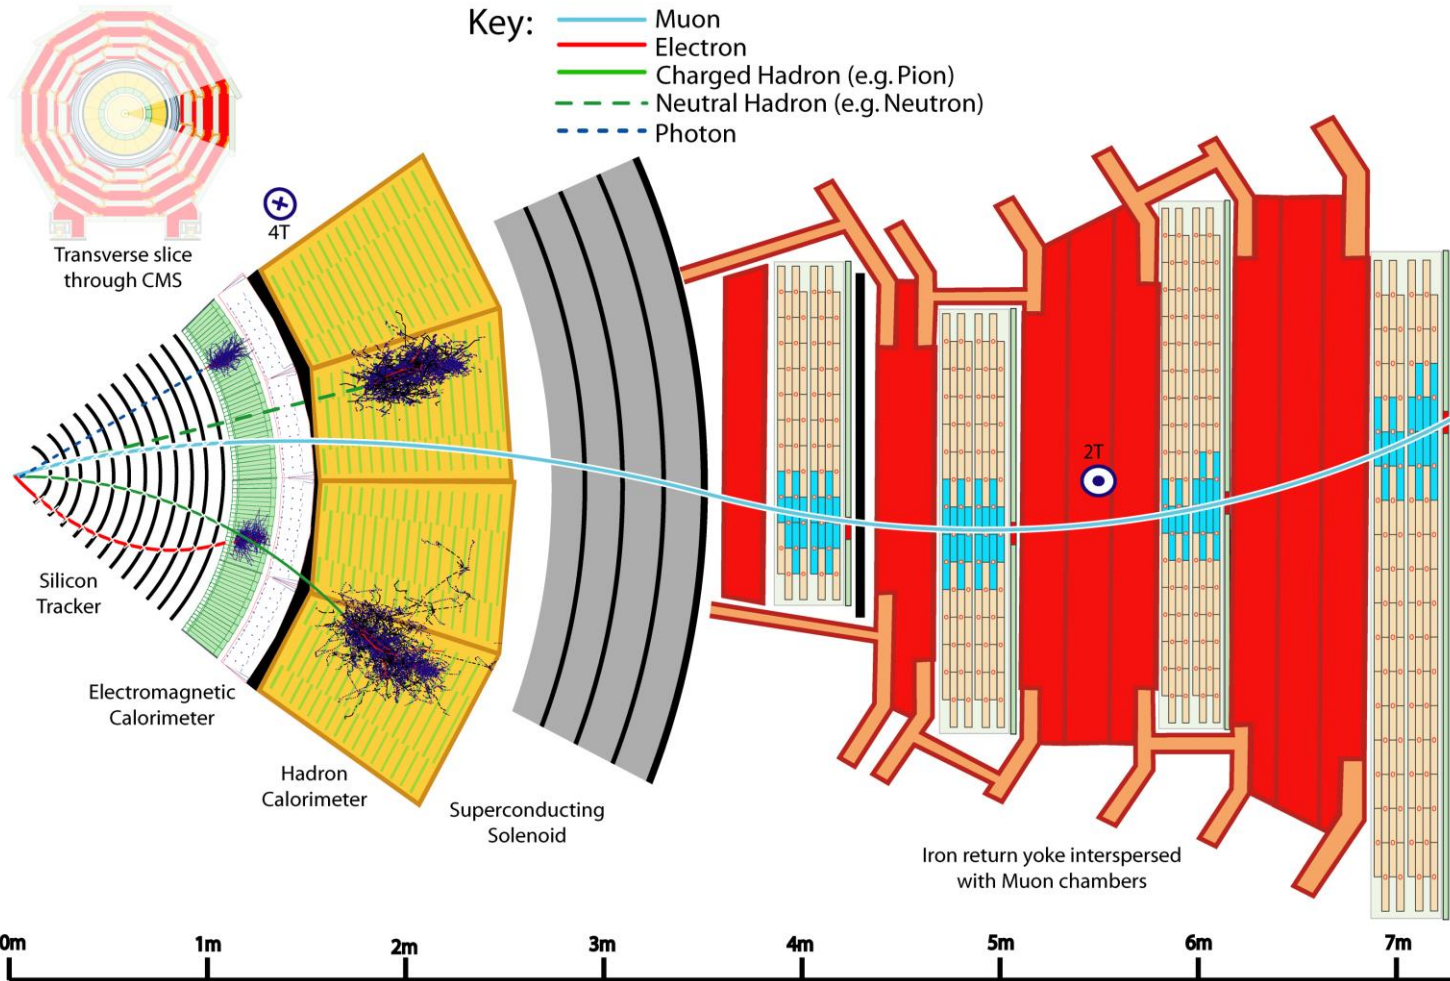

Identifying the collision event

Missing momentum

Group particles from the same interaction point – deduce source particle: $e^+e^- \rightarrow Z \mu^+\mu^- \rightarrow Z$ $2Z \rightarrow H$

Transverse vectorial momentum sum should be 0
If not, something is missing

Inner detector information geometrically precise, but amplitude information not needed

Good energy information in calorimeters and muon detector to determine missing momentum

Only transverse momenta considered, but all particles should be present – hermeticity

Detector signals are long, many bunch crossings, but must be associated with correct bunch crossing, if not, false missing momentum – **pile-up** problem at high count rates

Broken detector parts must be corrected for

E/M calorimeter should be deep enough to contain electrons and γ

Hadron calorimeter should be deep enough to contain hadrons

Radiation levels determine choice of detectors and electronics

Design compromises necessary for economical reasons

LHC Detectors

Heavy ion experiments,
Pb – Pb or Au – Au about 2 weeks/year

Low luminosity B physics

ATLAS -CMS

Similar but different – magnet system, detector solutions, TDAQ system
Competition – Collaboration

LHC results and cost

RESULTS so far

Higgs particle discovered 2012 July 4th (Nobel prize 2013)

No strong indications for BSM physics (Beyond Standard Model) yet

No SUSY (SuperSymmetry) yet

750 GeV bump exciting – could be something, or not – BSM in case it is – more next month

COSTS

LHC material costs ~3.1 G€

ATLAS material costs ~.3 G€

A Toroidal Apparatus - ATLAS

~ 1800 miles of cables
 ~10 MW of electric power
 2 to 4 Tesla mag. field

USA = Underground Storage Area
 100m below surface
 Access shafts 12 – 22 m diam.

Inner detector 1 bit? - ~86 Mch

E/M calorimeter 16 bit - ~300 kch

Hadron calorimeter 16 bit ~10kch

Muon detector x bit ~100 kch

Weight 7000 tons

3000 physicists + x engineers

174 institutes from

38 countries

Inner detector 1 bit? - ~86 Mch
 E/M calorimeter 16 bit - ~300 kch
 Hadron calorimeter 16 bit ~10kch
 Muon detector x bit ~100 kch

Weight 7000 tons
 3000 physicists + many engineers
 174 institutes from
 38 countries

CMS – Compact Muon Solenoid

CMS Collaboration

36 Nations, 159 Institutions, 1940 Scientists (February 2003)

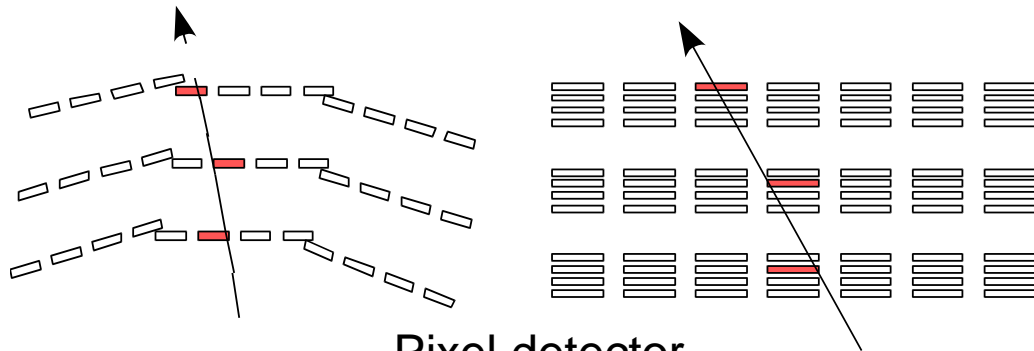

ATLAS installation

ATLAS installation

ATLAS inner detector

Pixel detector

SemiConductor Tracker

TRT

Straw tube

Magnetic field 2T
3 different detector types

Pixel detector 80 Mch
Silicon pad detector 2D resolution $12 \mu \times 110 \mu$

Semiconductor Tracker (SCT) 6 Mch
Silicon strip detector (1D)
Double layers Resolution $23 \mu \times 800 \mu$

Transition Radiation Tracker (TRT) 300kch
Gas detector – straw tubes
Electron identification

Gas detector – straw tubes
Electron identification

ATLAS inner detector

Magnetic field 2T
3 different detector types

Pixel detector 80 Mch
Silicon pad detector 2D resolution $12\ \mu \times 110\ \mu$

Semiconductor Tracker (SCT) 6 Mch
Silicon strip detector (1D)
Double layers Resolution $23\ \mu \times 800\ \mu$

Transition Radiation Tracker (TRT) 300kch
Gas detector – straw tubes
Electron identification

Pixel detector 3 sample points
Strip detector 4 sample points
TRT 36 sample points

About 1000 particles

Radiation tolerance, power and cooling problematic

Liquid Argon e-m calorimeter

Liquid Argon-Lead/stainless steel calorimeter (87°K)

16-bit dynamic range

Cooled preamplifiers

4 layers + presampler

TileCal hadron calorimeter

Interleaved steel and scintillator tiles

256 modules, each weighing 10 tons

4 depth layers

Coarse spatial but good amplitude resolution

Wave Length Shifting fiber
– good light transfer

The Muon Detector

Geometrical alignment precision $30 \mu\text{m}$

Alignment can change due to temperature change or deformations when the magnet field is changed

Cost → Use gas detectors, different types for precision and trigger and different types for normal and high intensity regions, close to beam pipe

MDT (Monitored Drift Tubes) and CSC (Cathod Strip Chambers) for high precision. CSC for high intensity forward regions

RPC (Resistive Plate Chambers) and TGC (Thin Gap Chambers) for trigger. TGC for high intensity regions.

The Muon Detector

RPC – Resistive Plate Chamber

MDT – Monitored Drift Tubes

Micromegas for muon detector upgrade

Trigger and Data Acquisition (TDAQ)

Reading out all data, every bunch crossing, completely impossible - data transfer limitations
Solution -> use multilevel trigger – data storage limitations, radiation tolerance

First level trigger – pipe-lined processing (in FPGAs) of merged calorimeter and muon data with reduced spatial and amplitude information - delivers Regions Of Interest

Second level trigger – PC based software processing full resolution data from all subdetectors but only from RIOs

Third level trigger – Event Builder – PC farm to on-line analyze all data at highest precision

A first selection criteria is to require large transverse energy components to guarantee a head-on collision

Trigger and Data Acquisition (TDAQ)

First level trigger

The Calorimeter trigger processor and the Muon trigger processor reports to the **Central Trigger Processor (CTP)**

CTP looks for characteristic signatures in the data that indicates that the data contains an interesting event e.g.

- 4 isolated electrons or
- 4 muons or
- 2 high energy electrons over a certain threshold and 2 jets
- etc.

The search criteria are defined in the **Trigger Menu** data base

The current Trigger Menu selection is defined at the start of a run

All data can be stored on the detector for maximum $2.5 \mu\text{s}$ – the **latency** of the first level trigger

Before this, a decision must be made on saving or not saving that data

The specified data latency allows for sending the data from the detector to the trigger processor in USA-15 (Underground Storage Area), process it and send the result back to the detector for possible transmission of the entire data set.

First level trigger

Each bunch crossing, i.e. each 25ns

4096 trigger data values arrive from LAr and Tile

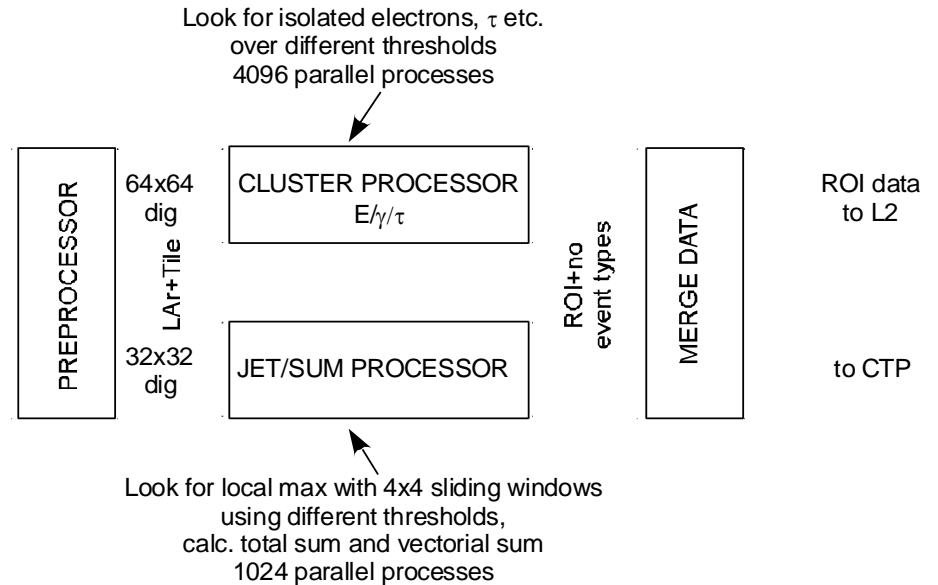

64 cell rows around the calorimeter cylinder and 64 cells in each row along the detector

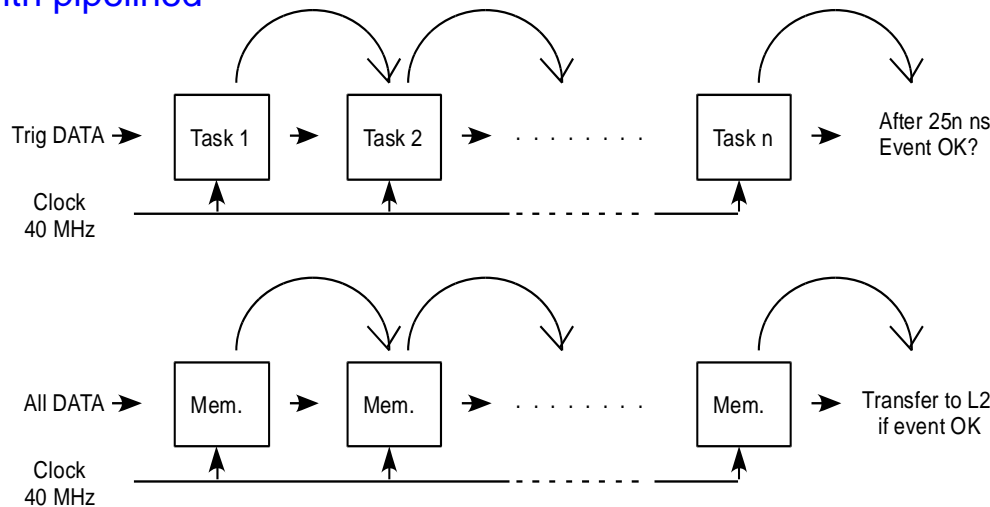

For each corresponding trigger cell one must study if it contained an interesting event

4096 parallel processes start every 25ns and should be completed within 1 μs

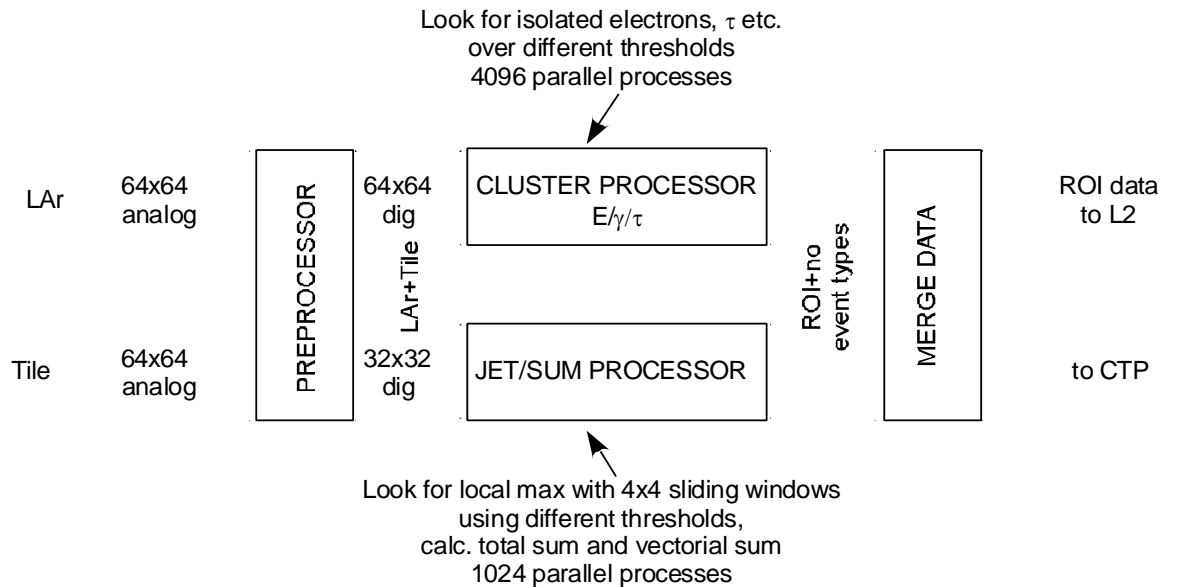

FPGAs widely used together with pipelined processing

PIPELINED PROCESSING

First level trigger

CLUSTER FINDING e/γ ALGORITHM

For each cell and each set of thresh.

Vert. SUM or Hor. SUM > thresh.

Em isolation SUM < thresh.

Had isolation SUM < thresh.

JET MAX ALGORITHM

Condition for jet maximum: $E_{NW}, E_{SW}, E_{SE}, E_{NE} < E_0$

Synchronization

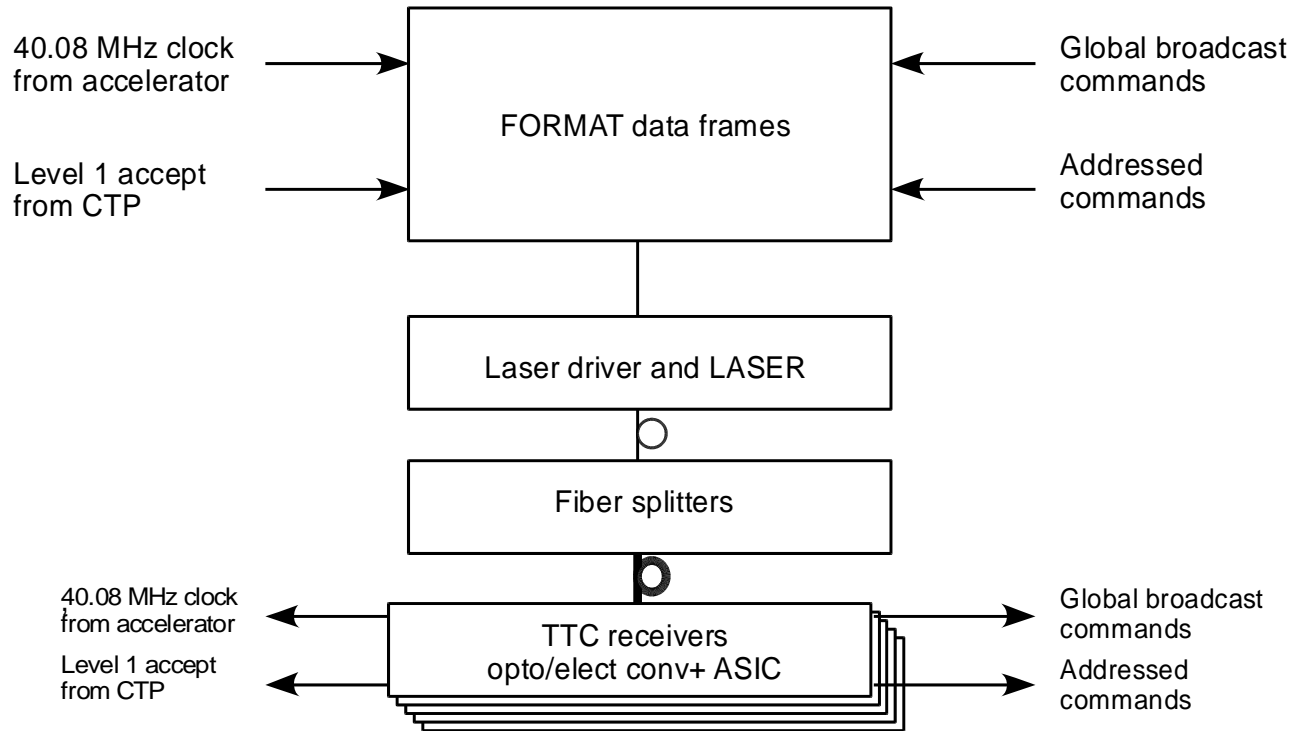

The Timing, Trigger and Control (TTC) system is responsible for synchronization

The accelerator clock 40.08 MHz distributed to all Front-End units with local phase control

L1A distributed to all FE-boards with programmable delay to maintain sync.

Addressed commands to configure local FE-boards

Maintains Bunch Crossing Identifier BCID to label events

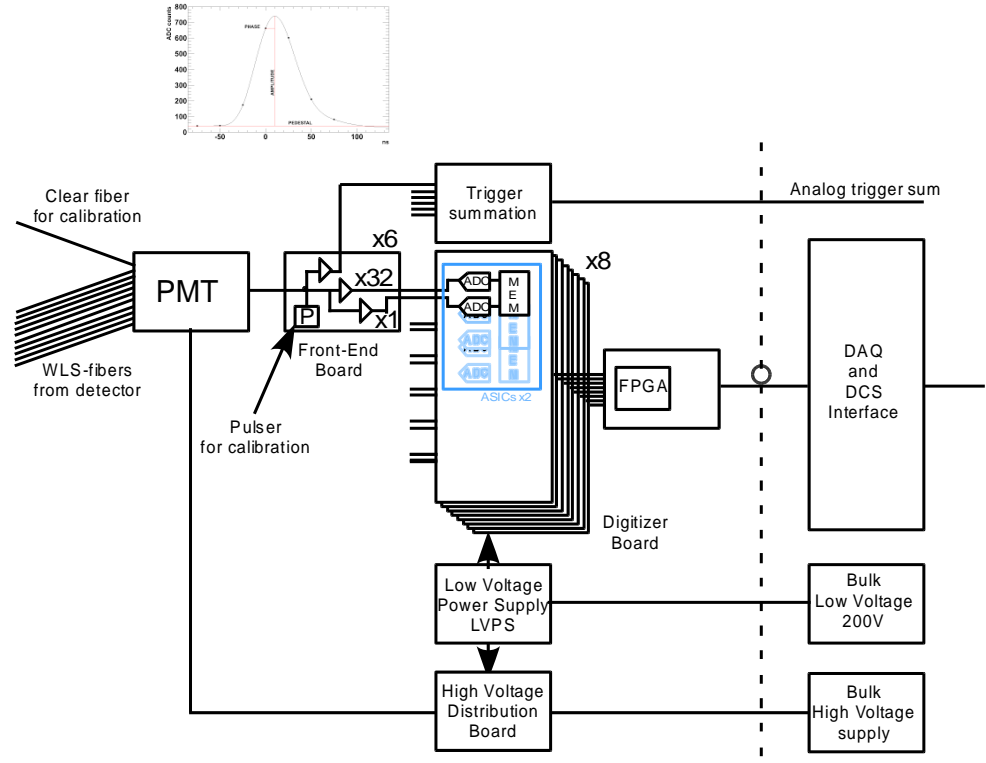

Detector Control - DCS

The Detector Control System or Slow Control, as it was called before, is responsible for initializing all system components including configuring the FPGAs

It is also responsible for safety functions

Front-End example - TileCal

4x64 modules (with electronics in "drawers") with 46 or 32 PMTs each read out by 2 10 bit ADCs (high and low gain)

256x8 Digitizer boards with 2 ASICs each containing digital pipeline and de-randomizer

Analog trigger signals – digitized in USA-15

3 calibration methods: Charge injection, Laser and circulating source through detector

ATLAS upgrades

LHC have regular stops for longer maintenance and upgrade

End of operation 2035?

Upgrade phase 0

Prepare for full energy 13 TeV

Insertable B-layer – replace the inner pixel layer

Upgrade phase 1

3 times higher luminosity, need better algorithms

New Small Wheel

Topological trigger – not only count event but also consider their geometrical relationship

LAr fully digital trigger

New trigger architecture

Upgrade phase 2 – Prepare for HE-LHC (High Energy LHC)

10 times higher luminosity, need still better algorithms

New Trigger system – level 0 (L0a: 1MHz, Latency: 6 μ s)/level 1(L1a:<400kHz, Latency: <30 μ s)?

New inner detector – no TRT, track trigger (introducing track data into Level 1)?

New TileCal electronics – read out all data to USA-15 – fully digital trigger

Future

General trends

More on-detector FPGAs – new FPGAs more radiation tolerant to hard but not soft errors – develop correction strategies for soft errors

More high speed data transmission – 10 Gb/s or more

Early digitization

After 2035? FCC? ILC? CLIC?

Future Circular Collider
FCC
50+50TeV p – p
100 km circumference
Assumes new magnet technologies

BUT THIS IS FOR YOU!
