# What is JIVE?

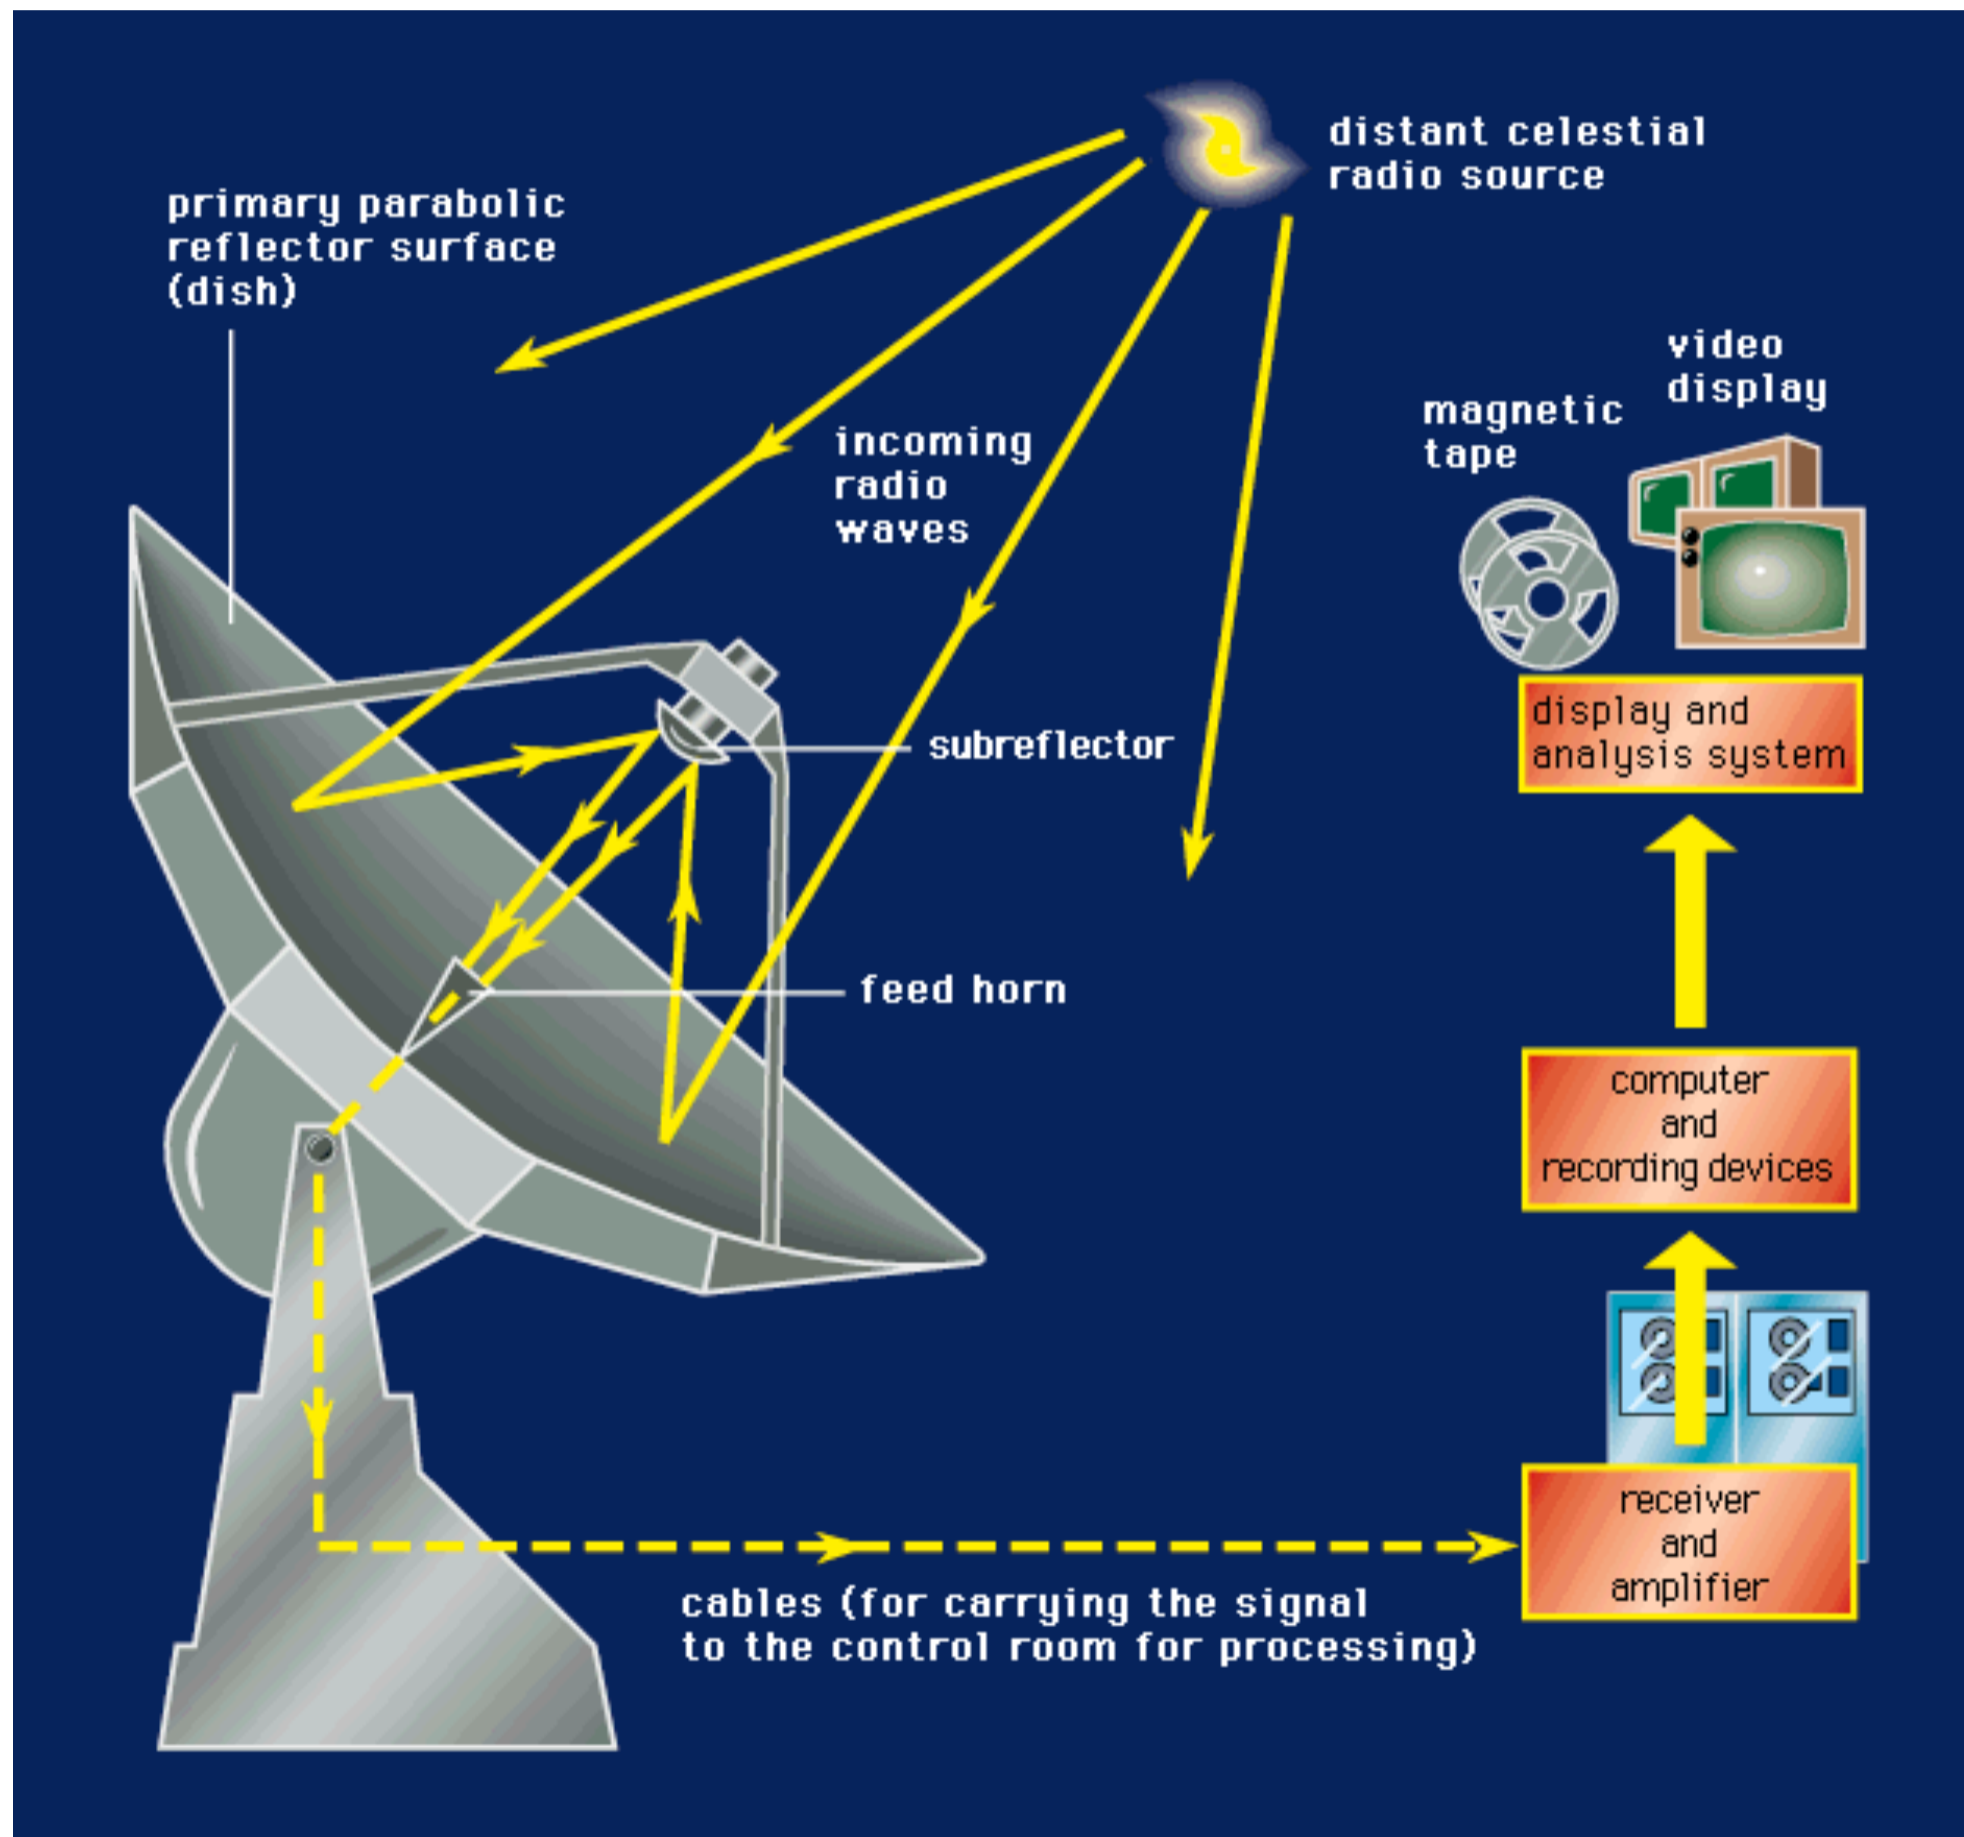

Operate the EVN correlator and support astronomers doing VLBI.

A collaboration of the major radio-astronomical research facilities in Europe, China and South Africa

A 3 year program to create a distributed astronomical instrument of inter-continental dimensions using e-VLBI, connecting up to 16 radio telescopes

# Radio Astronomy

# Radio vs. Optical astronomy

The imaging accuracy (resolution) of a telescope:

$$\theta \approx 1.2 \lambda/D \quad (\lambda = \text{wavelength}, D = \text{diameter})$$

Hubble Space Telescope:

$\lambda \approx 600\text{nm}$  (visible light)

$D = 2.4\text{m}$

$\theta = 0.06$  arcsecond

Onsala Space Observatory:

$\lambda = 6\text{cm}$  (5GHz)

$D = 25\text{m}$

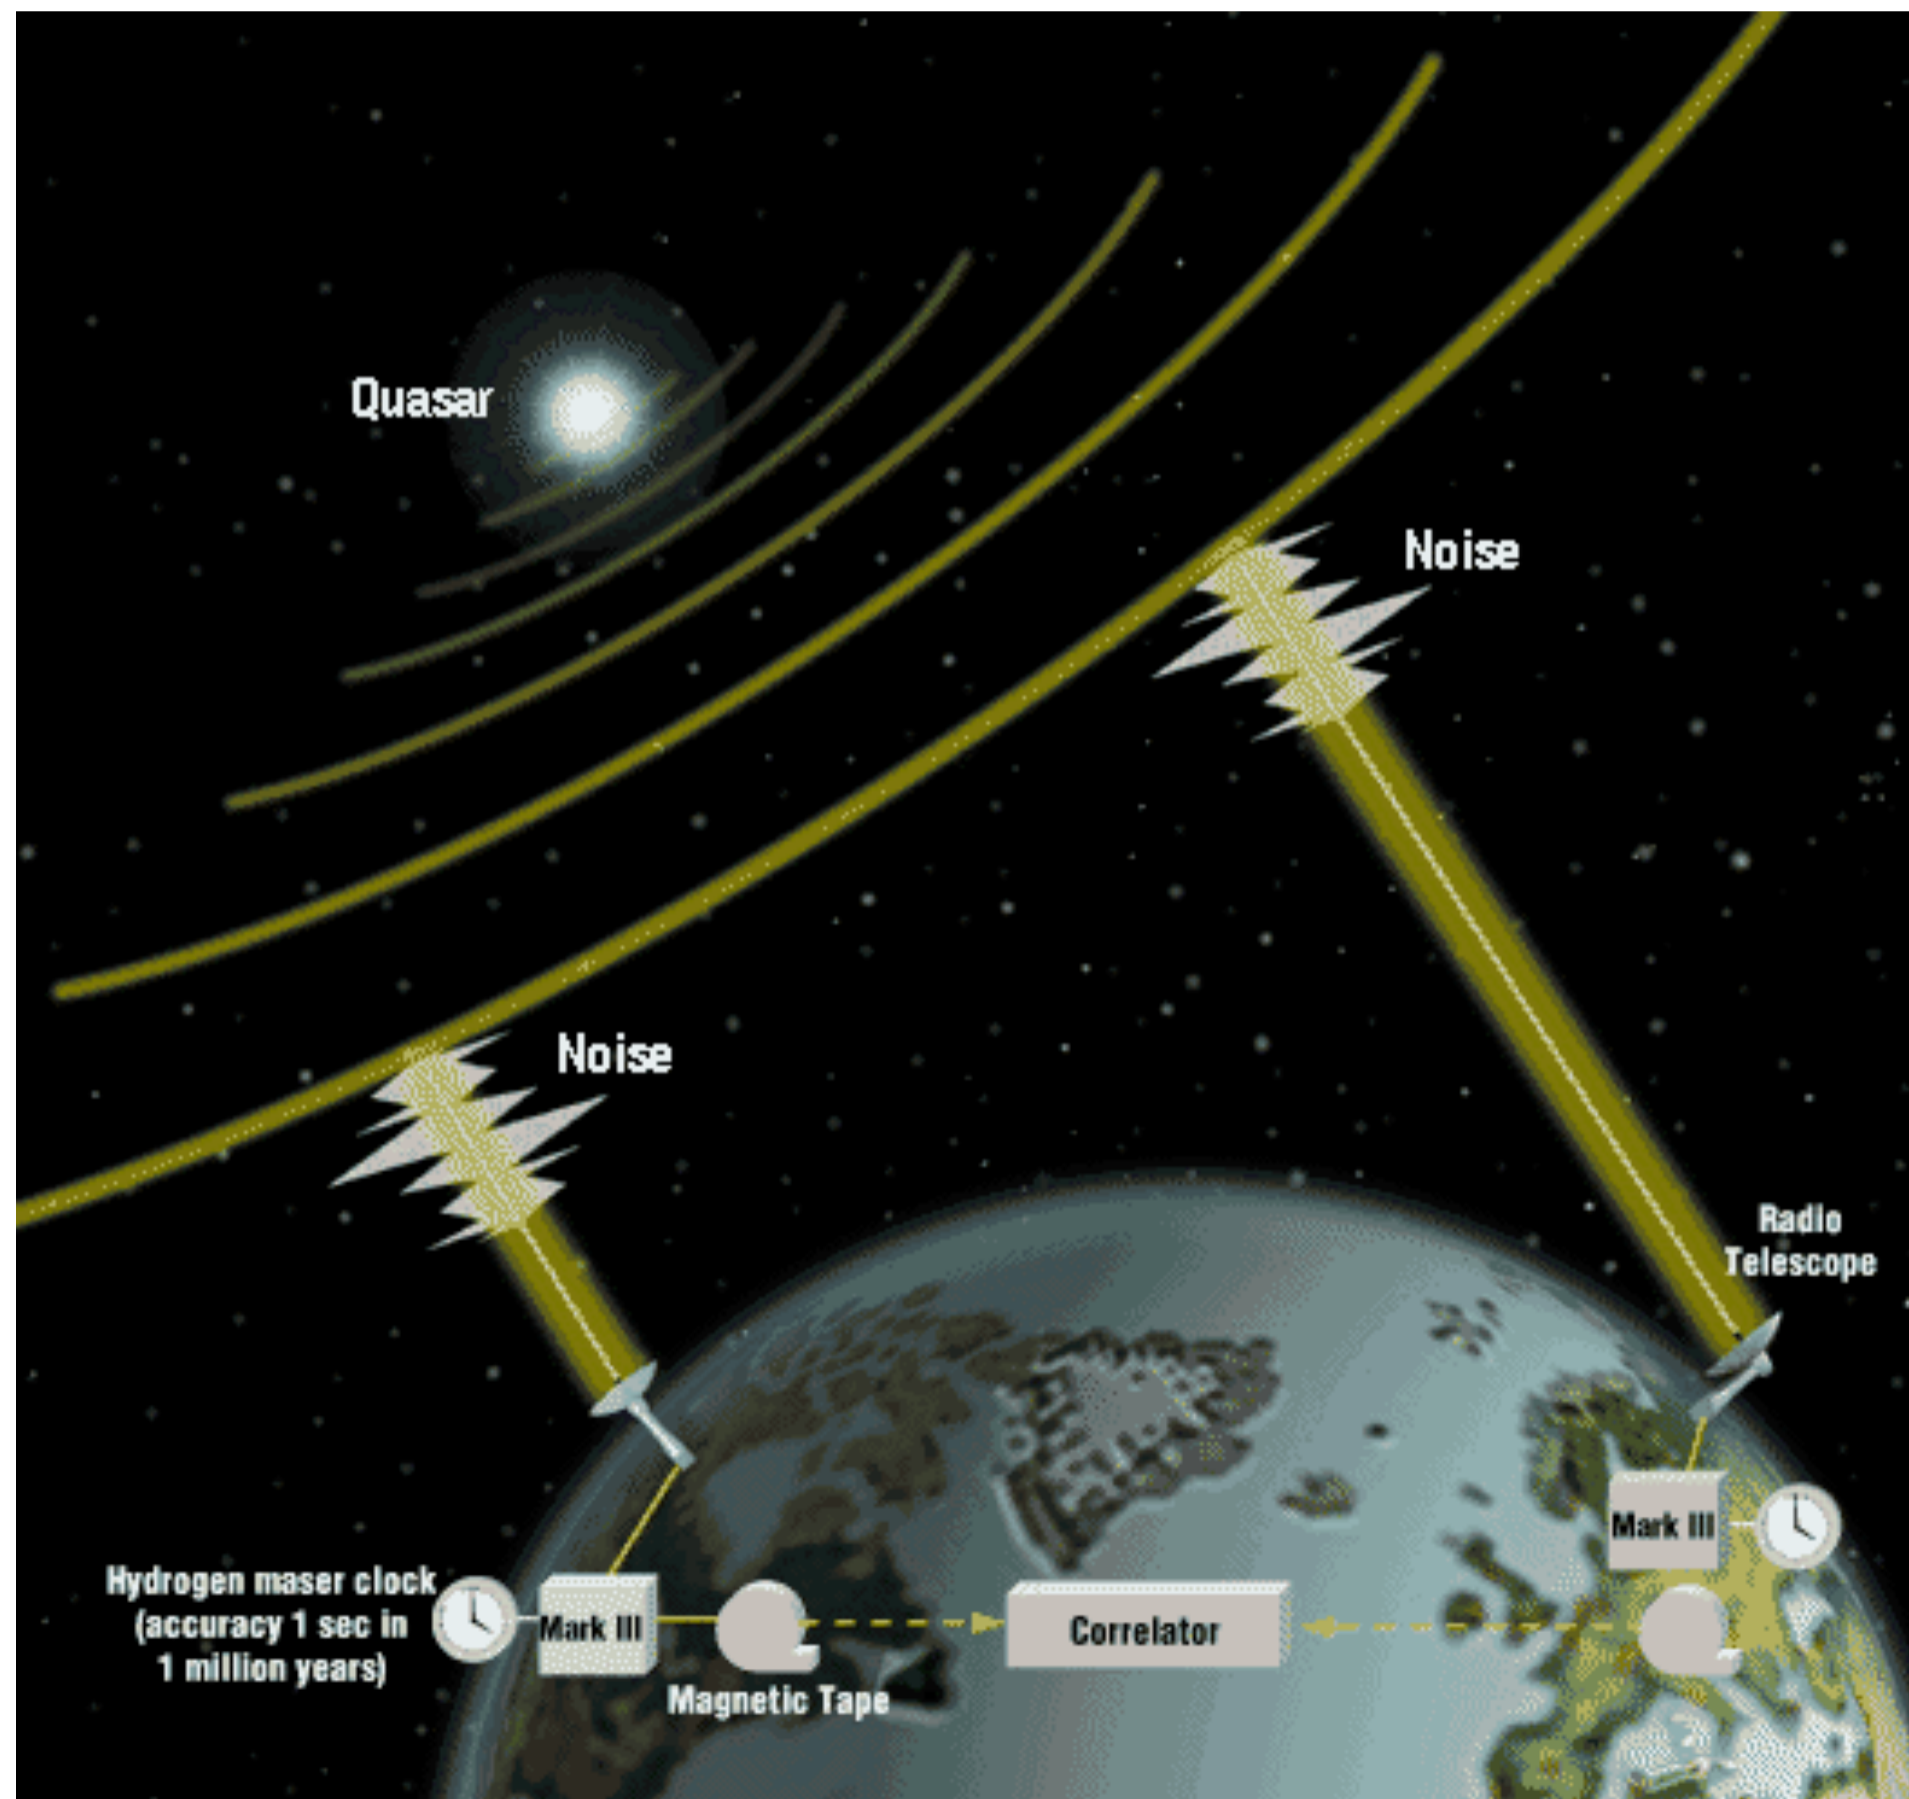

$\theta = 600$  arcseconds

Wanted: 240km dish

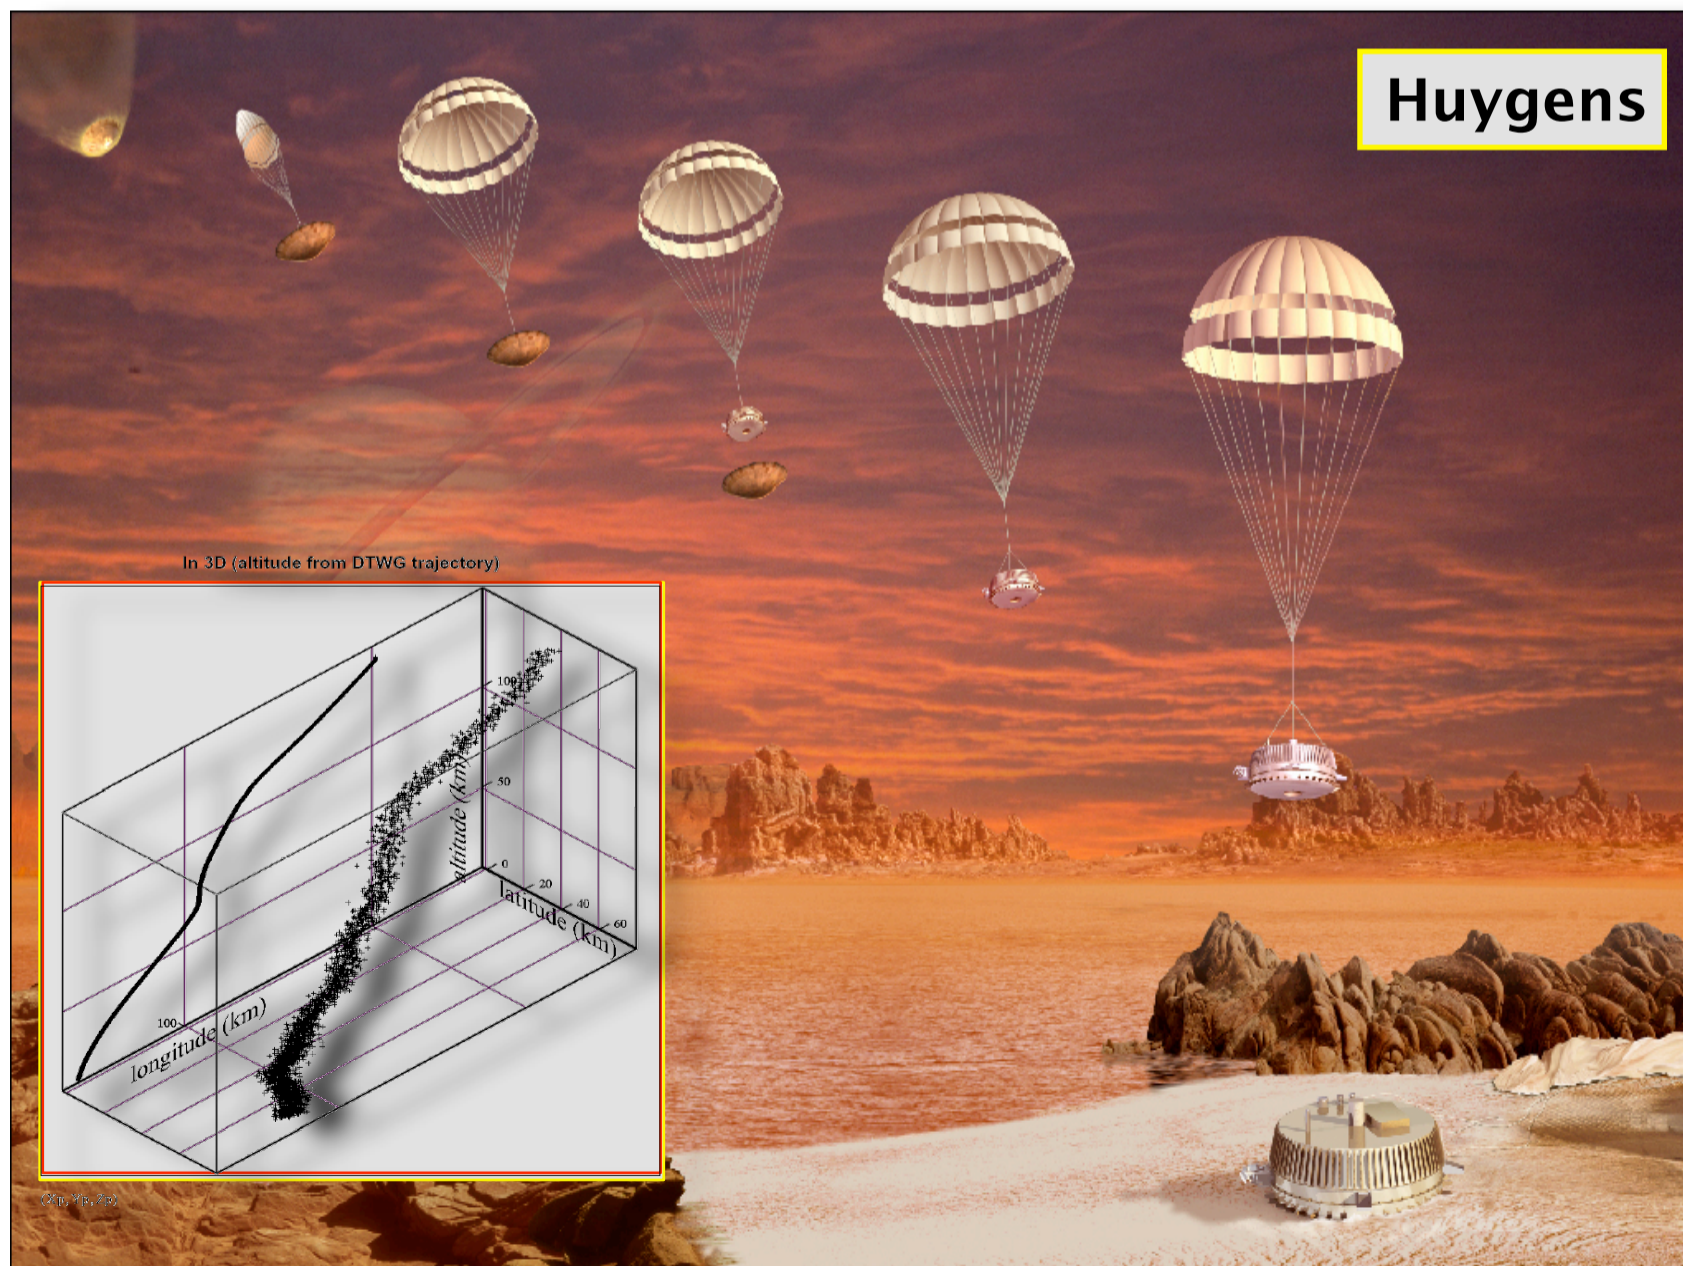

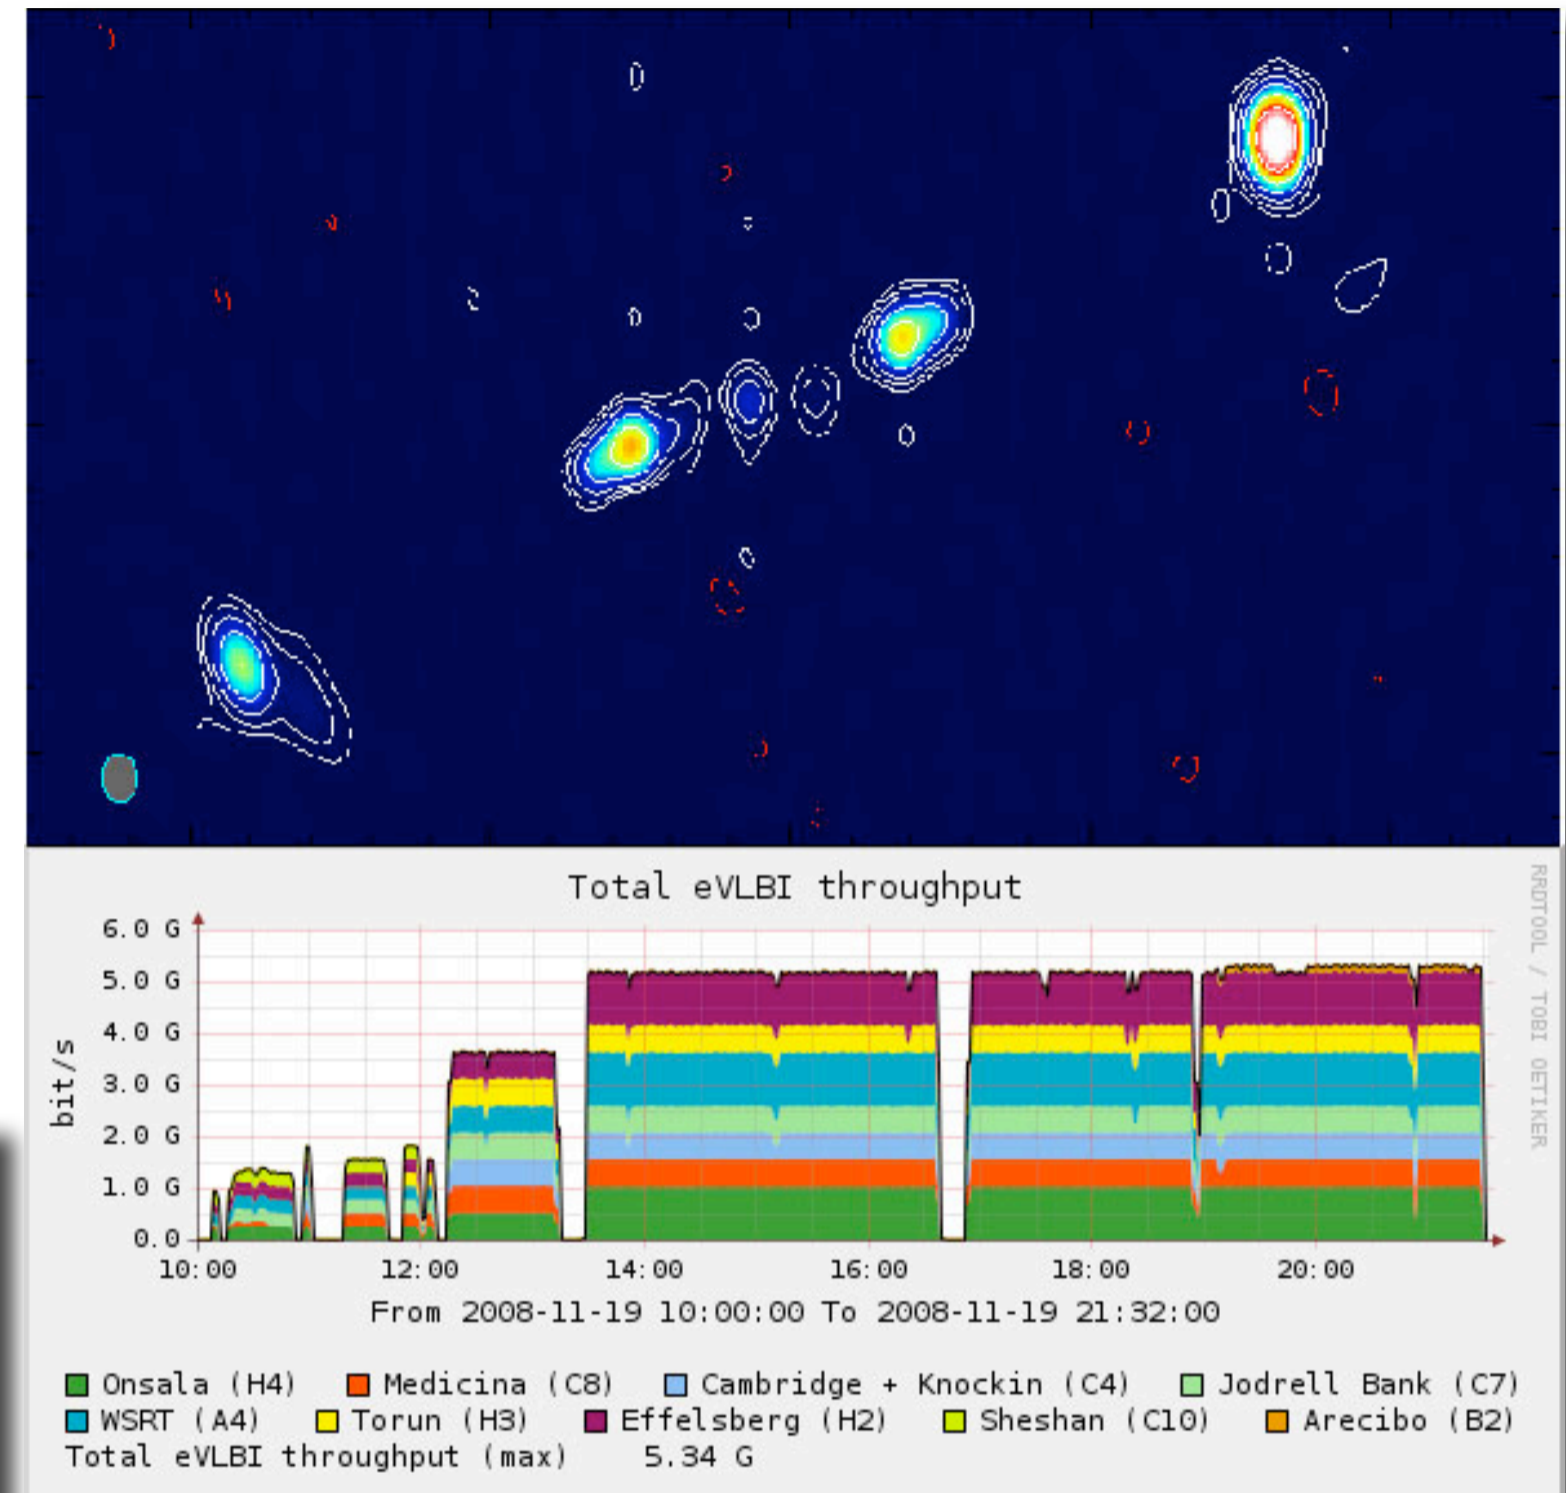

# Very Long Baseline Interferometry

- Create a huge radio telescope by using telescopes in different locations around the world at the same time

# Very Long Baseline Interferometry

- Highest angular resolution
- High sensitivity
- Observations typ. 12 hours
- Large data volume

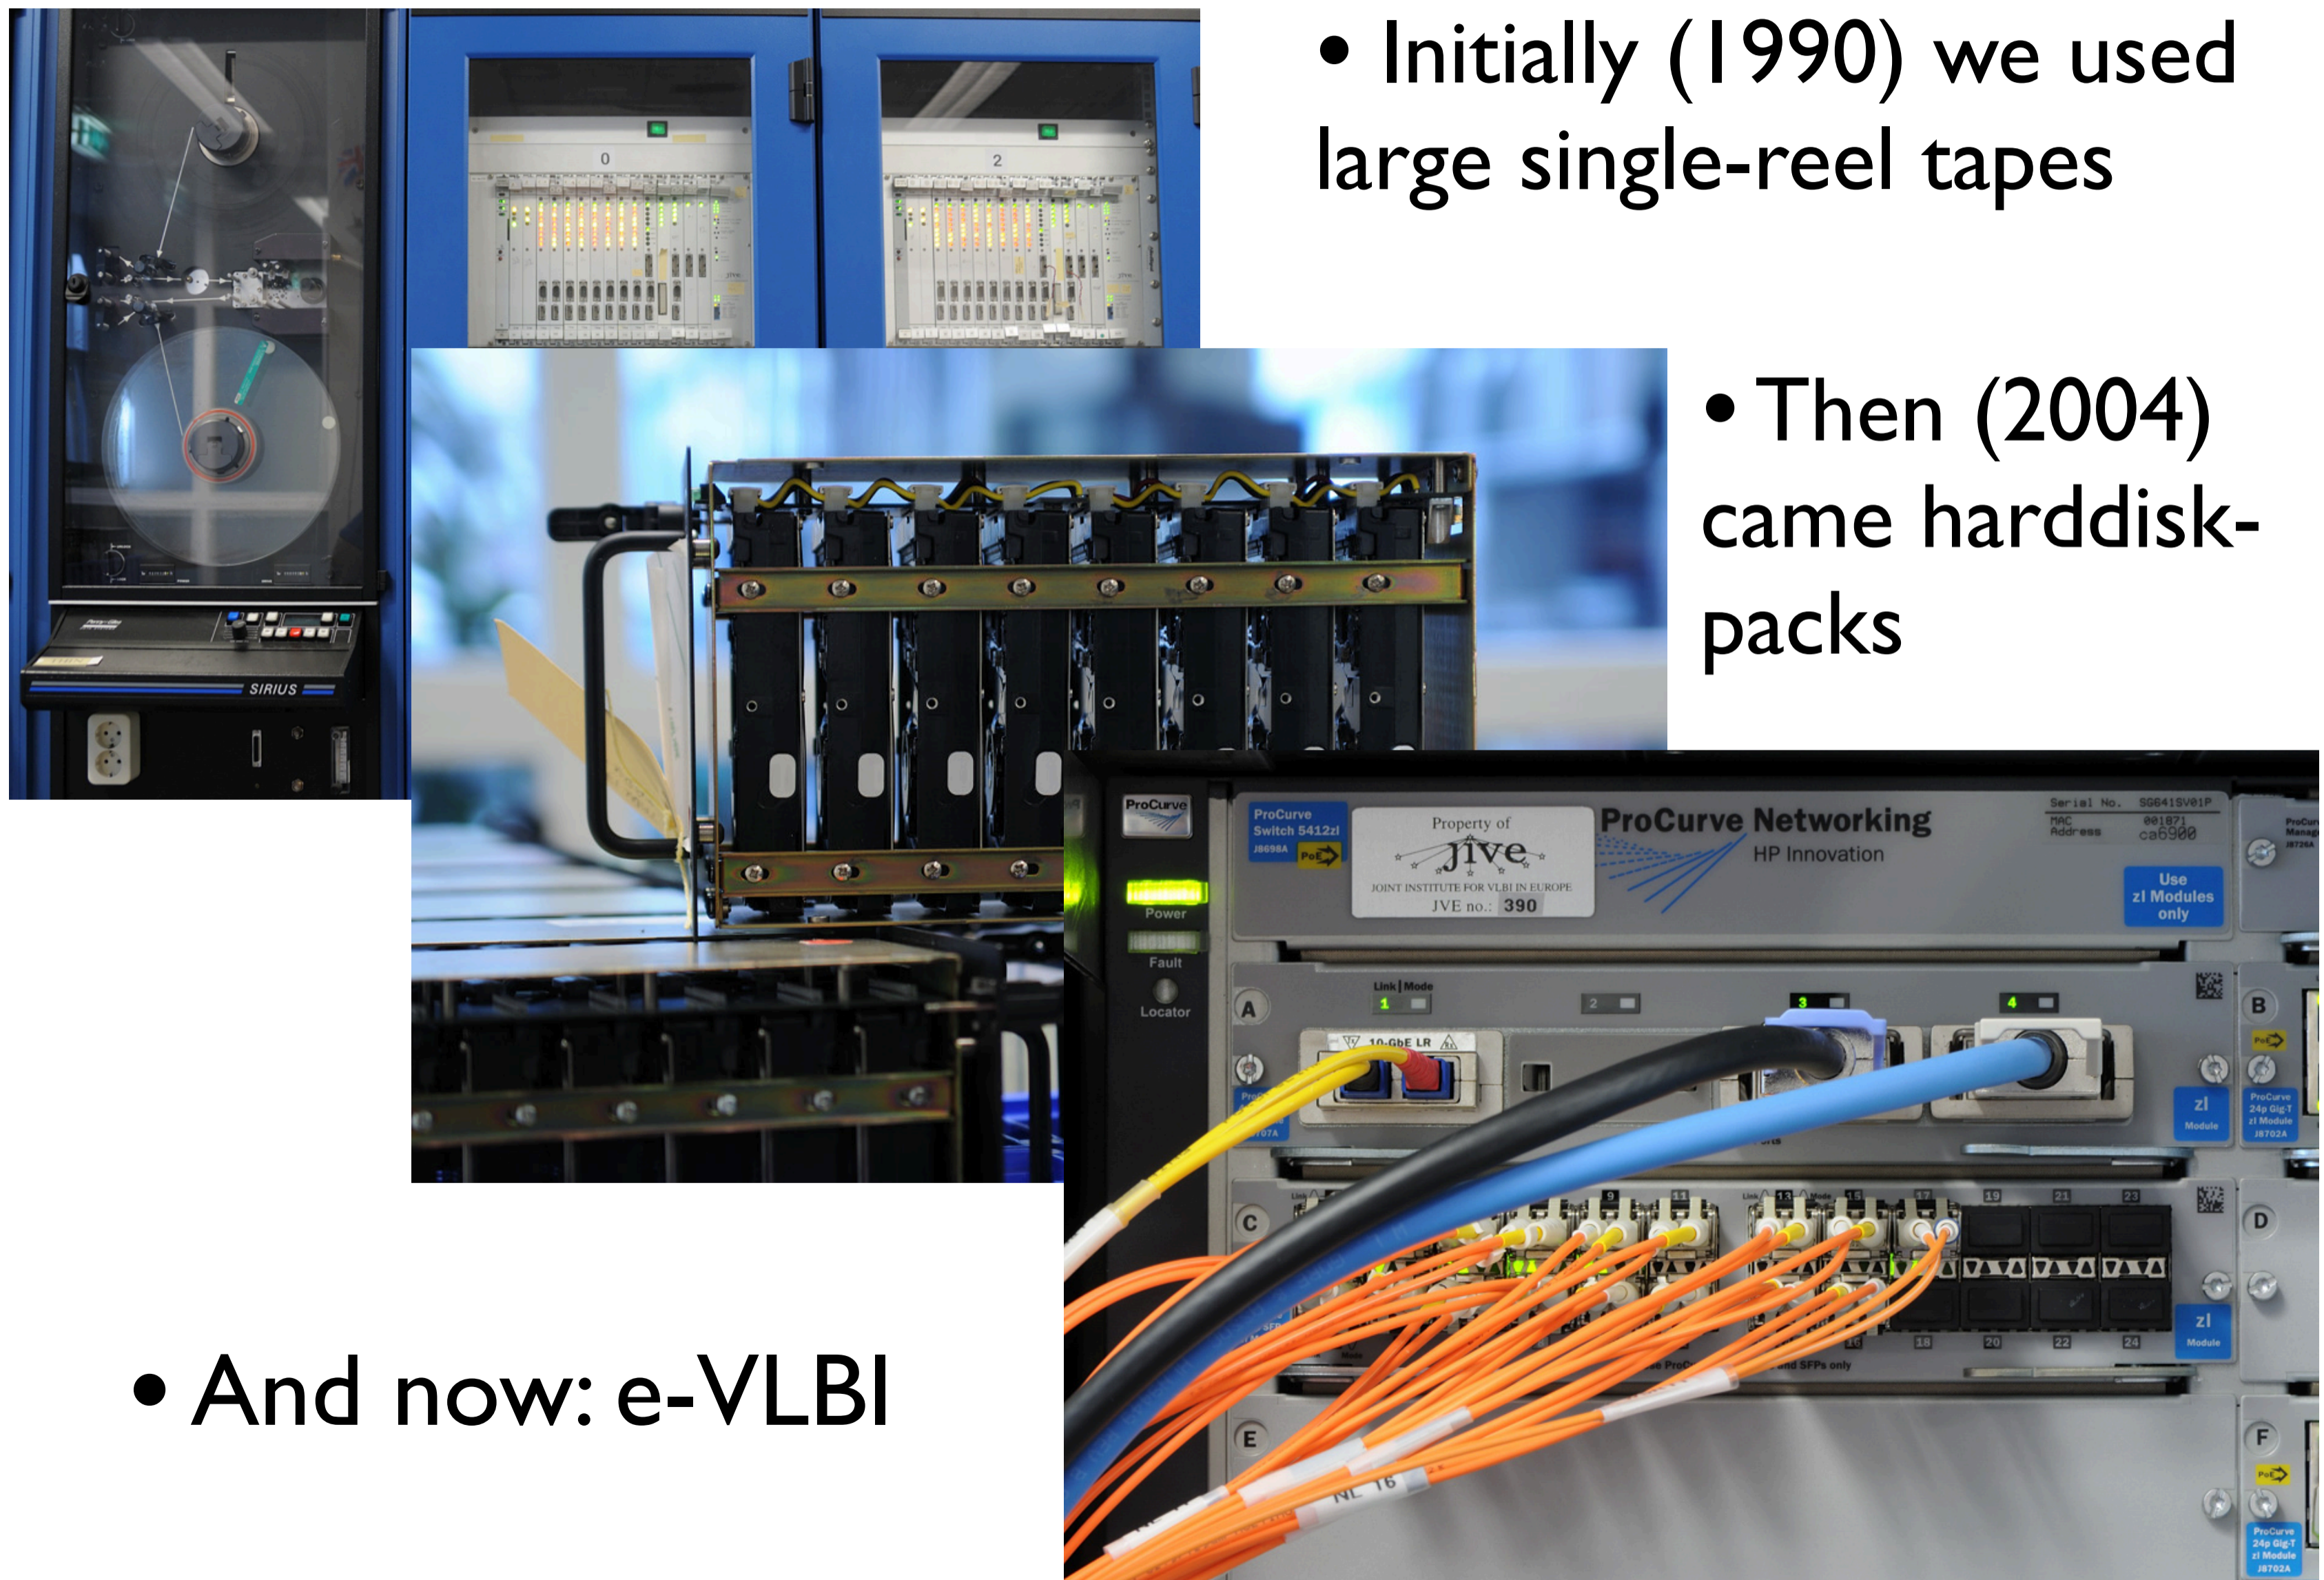

- Active Galactic Nucleae
- Supernovae, remnants, pulsars
- Spacecraft
- And much more

# Very Long Baseline Interferometry

- Initially (1990) we used large single-reel tapes

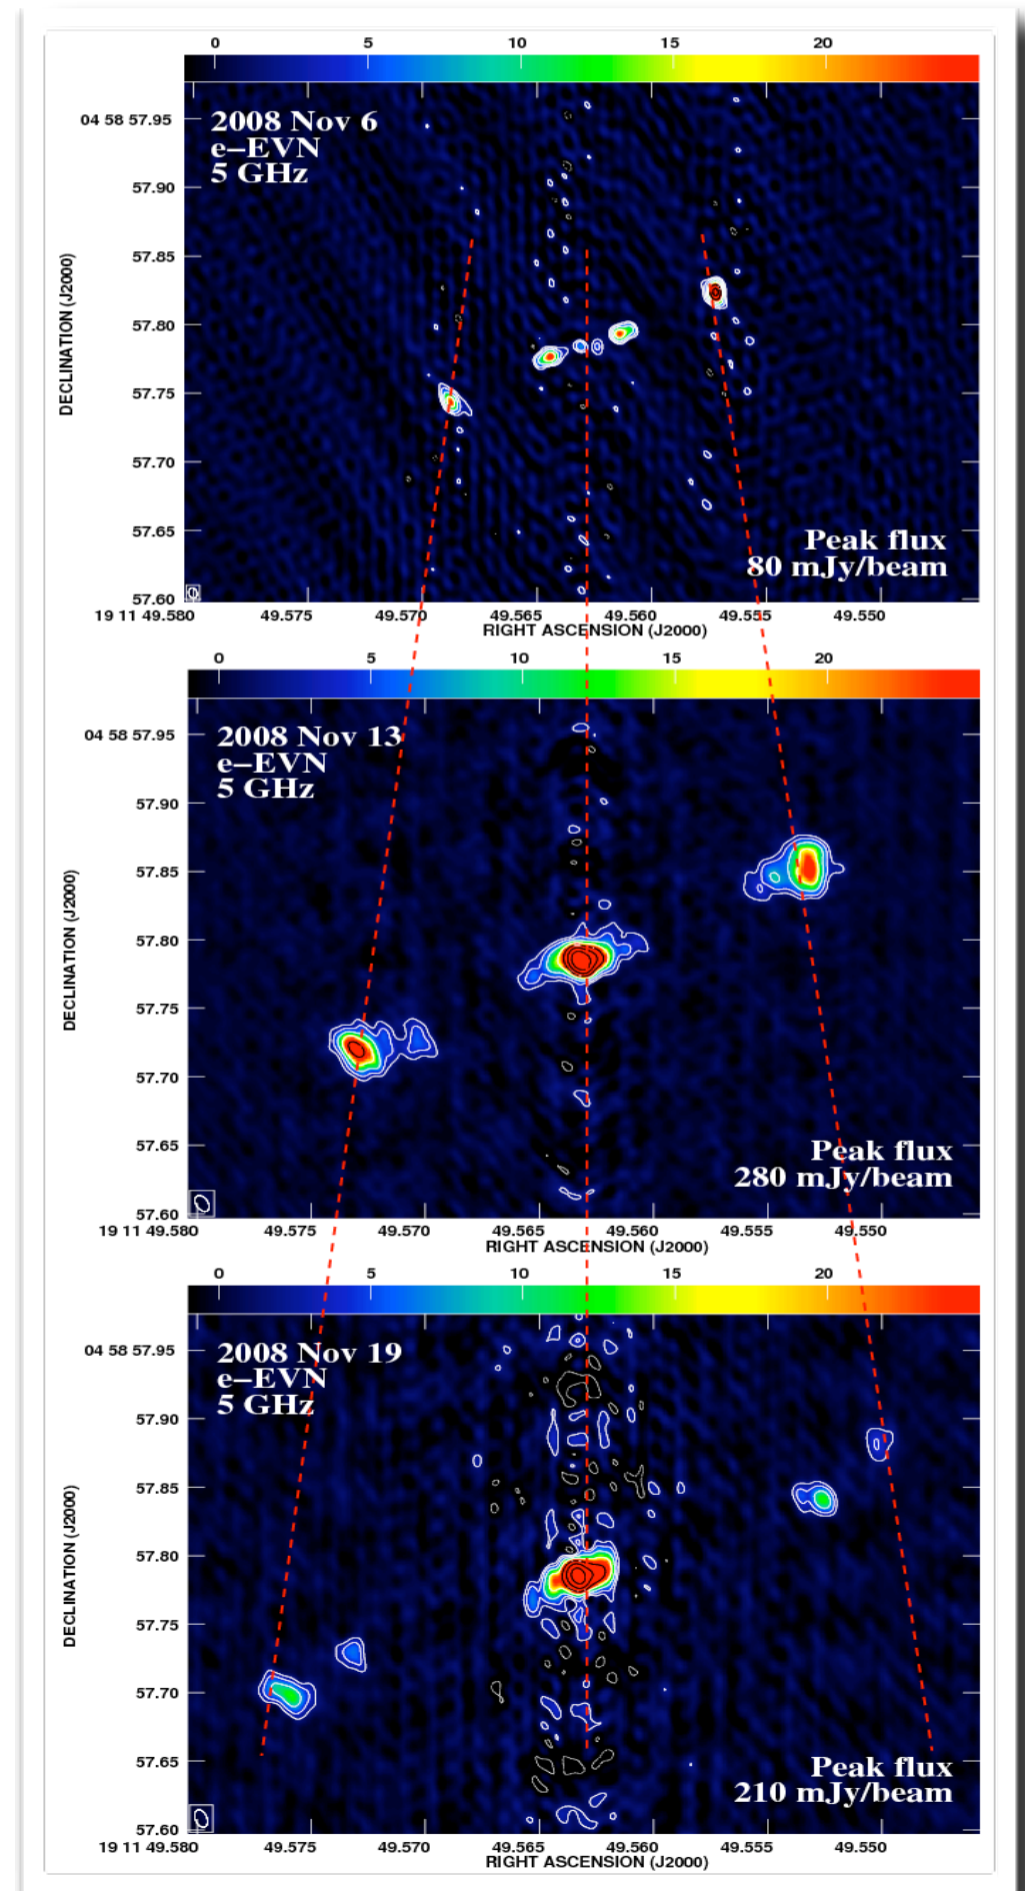

- Then (2004) came harddisk-packs

- And now: e-VLBI

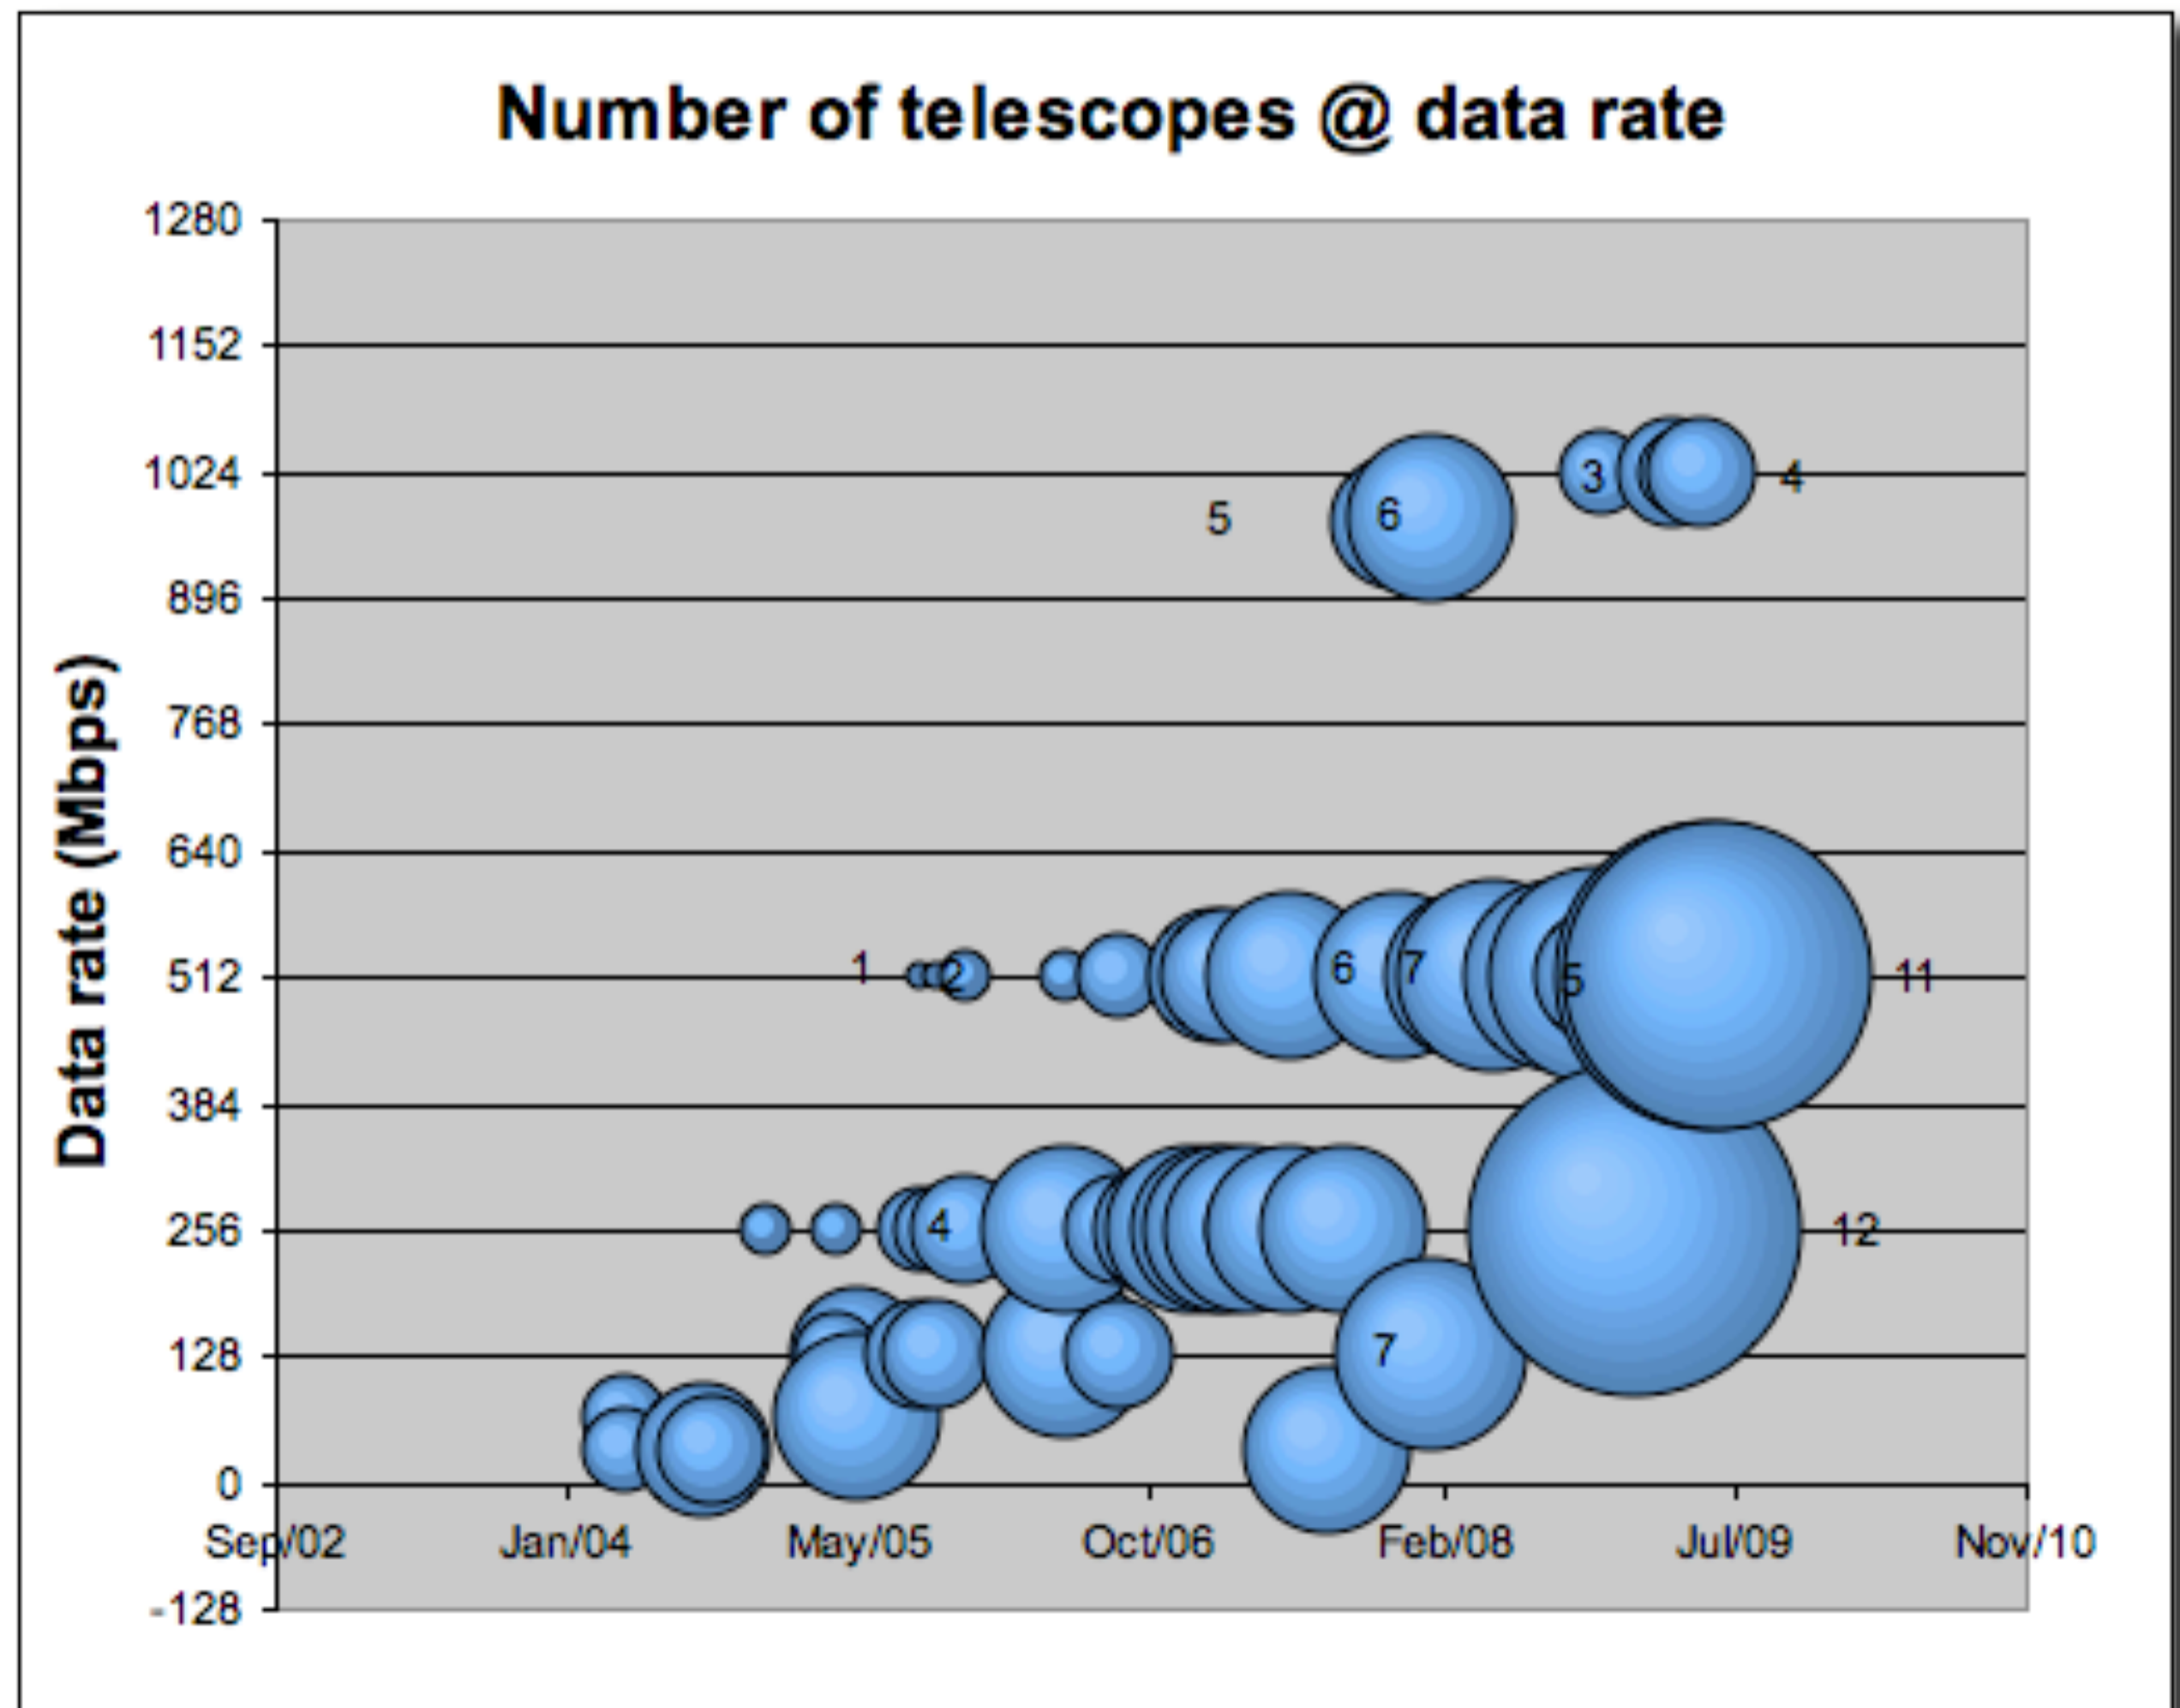

# The EXPRoS project

- EXPRoS ran from March 2006 to September 2009
- Funded by the EC
- Established competitive, real-time VLBI
- Regularly connecting  $> 10$  telescopes
- Global collaboration and reach
- Target-of-Opportunity observations
- Robust
- Producing new science

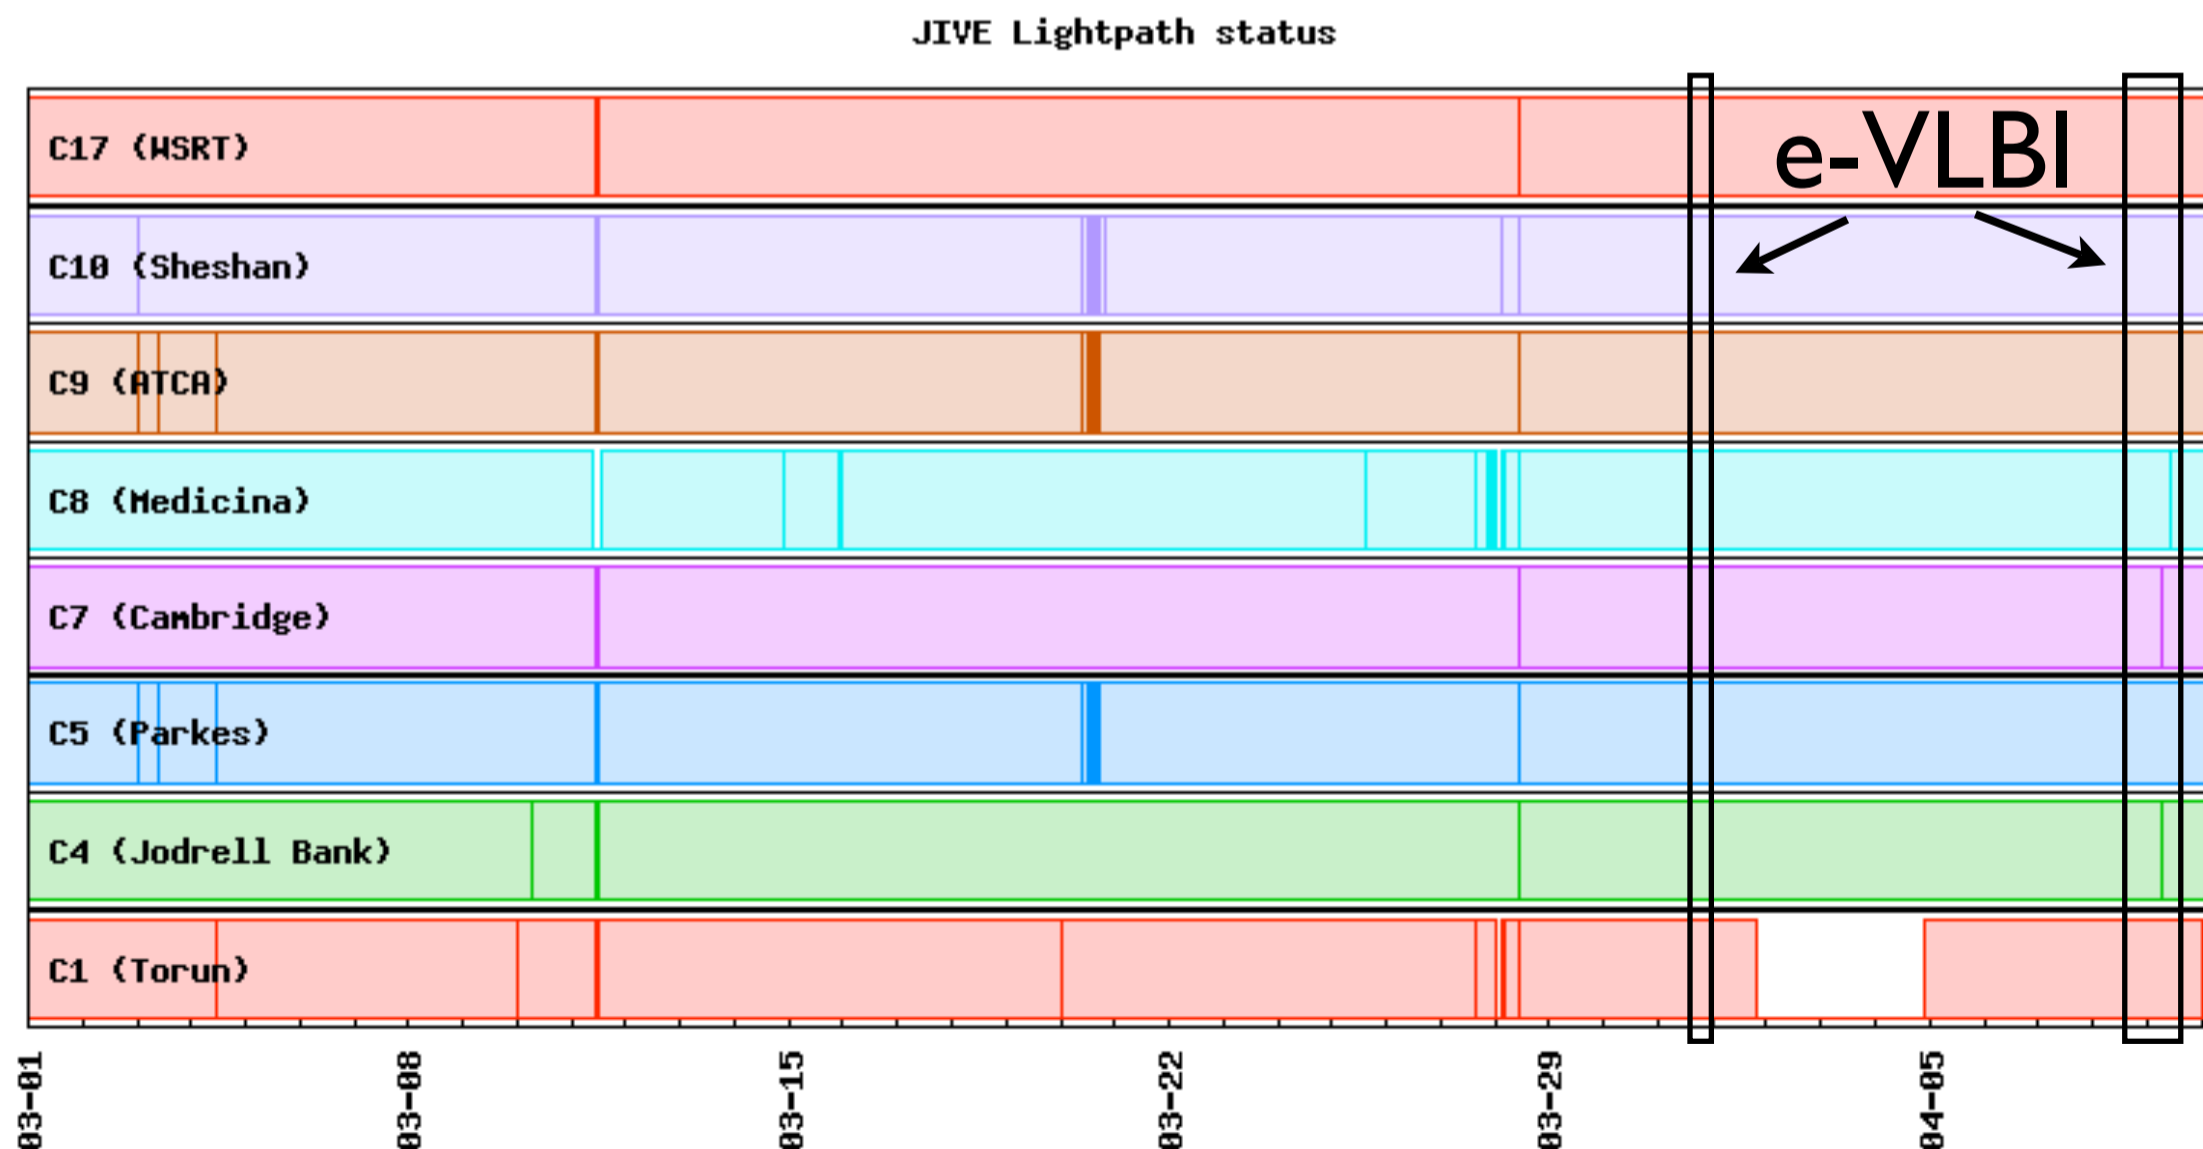

# The EXPRoS project

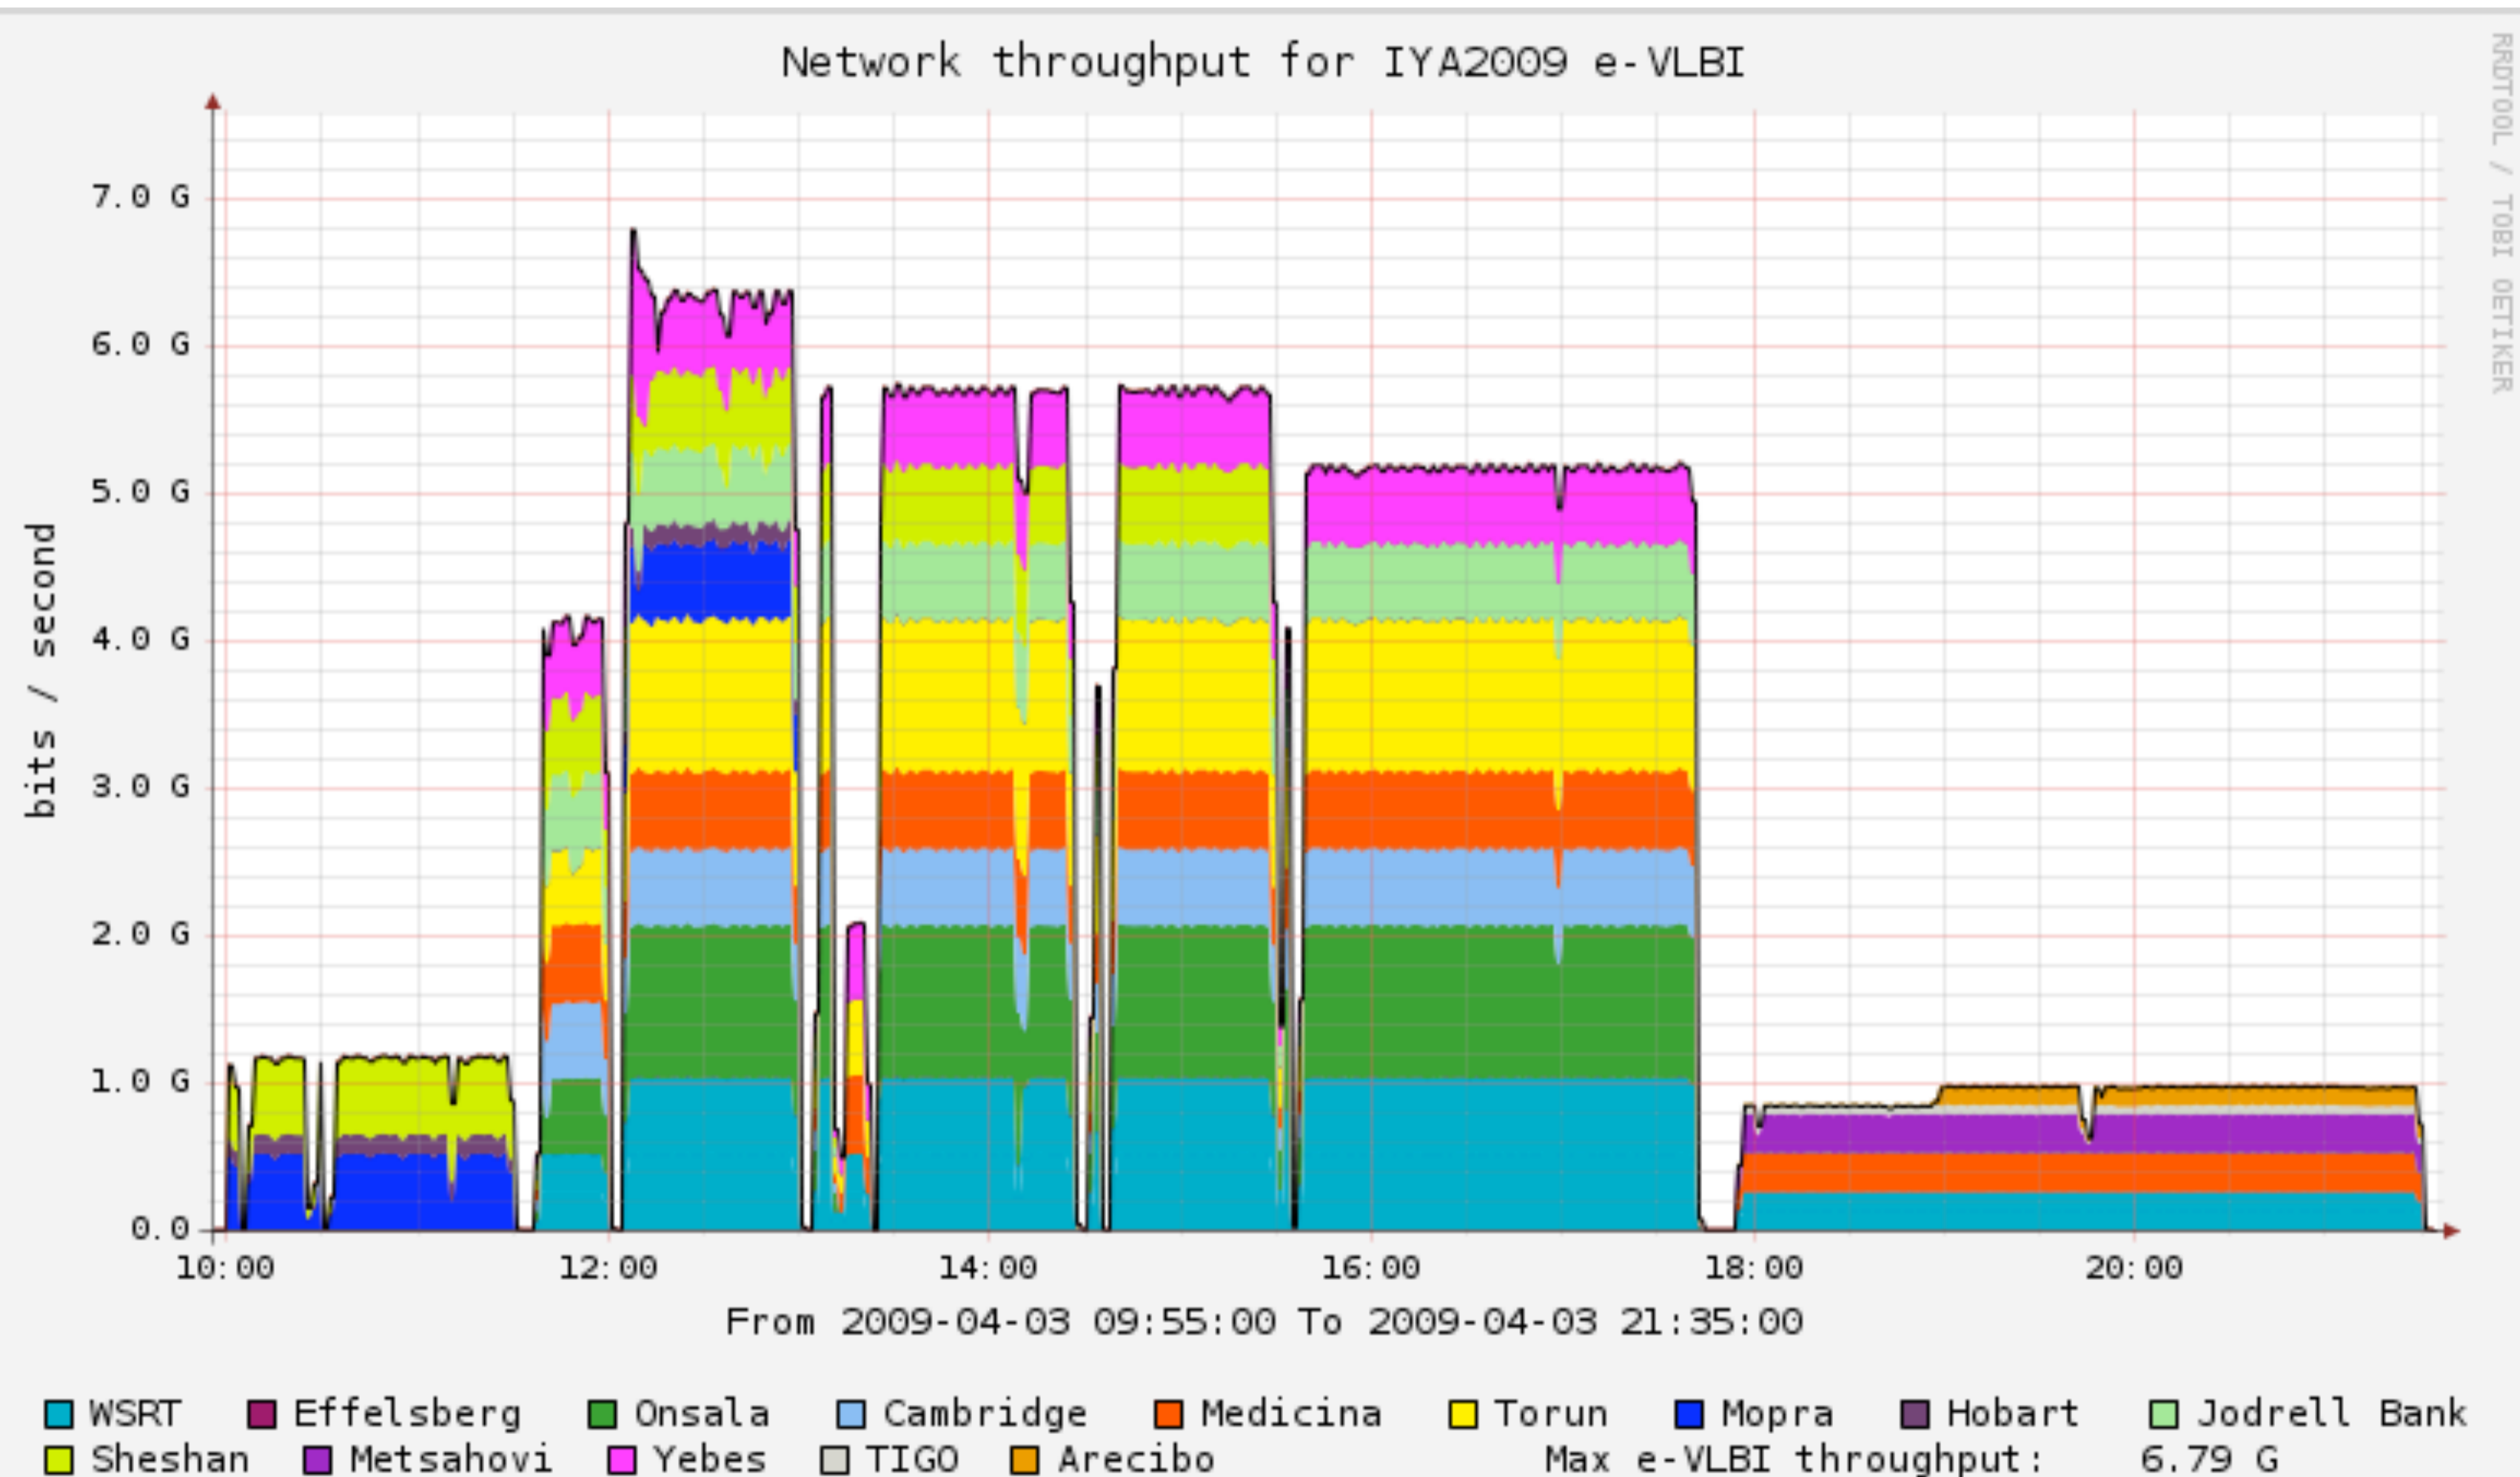

# Lessons from EXPRoS

- TCP does not perform well on long paths at high speed
- UDP requires overprovisioned or dedicated networks
  - Routed (research) networks, VLANs, Lightpaths
- Paths without redundancy have unscheduled outages

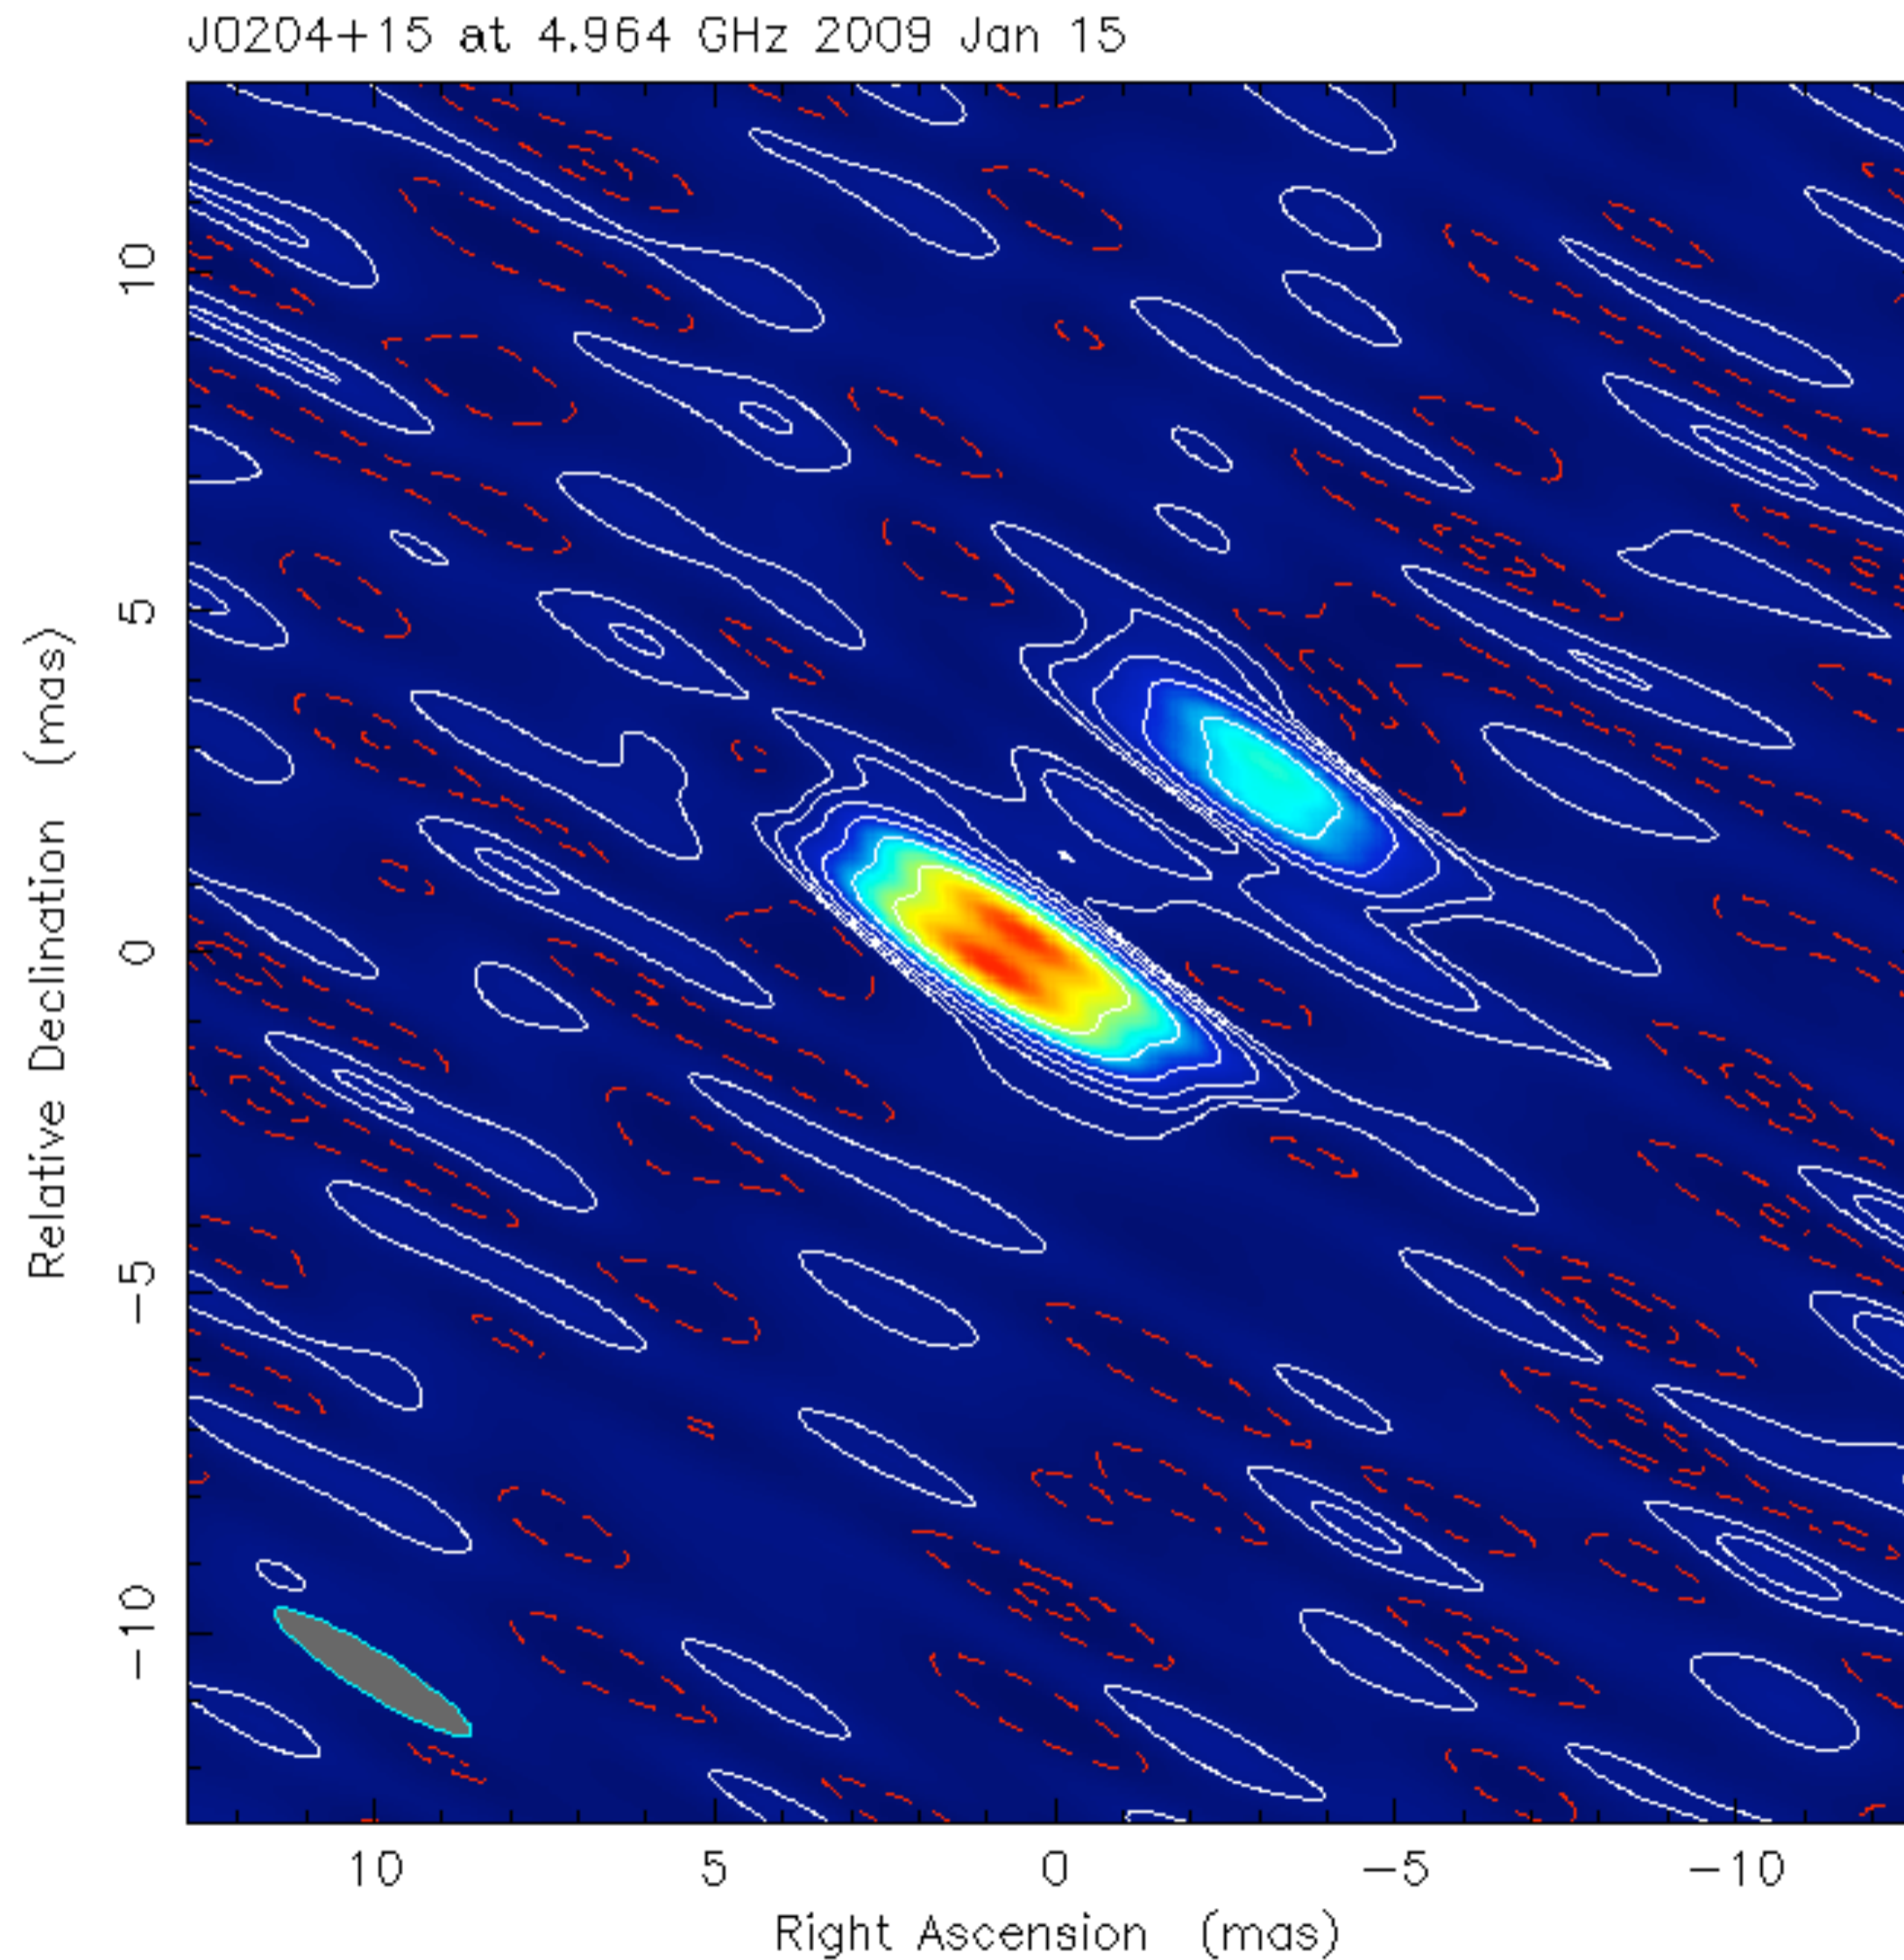

- Especially the long-haul paths
- e-VLBI is robust and efficient

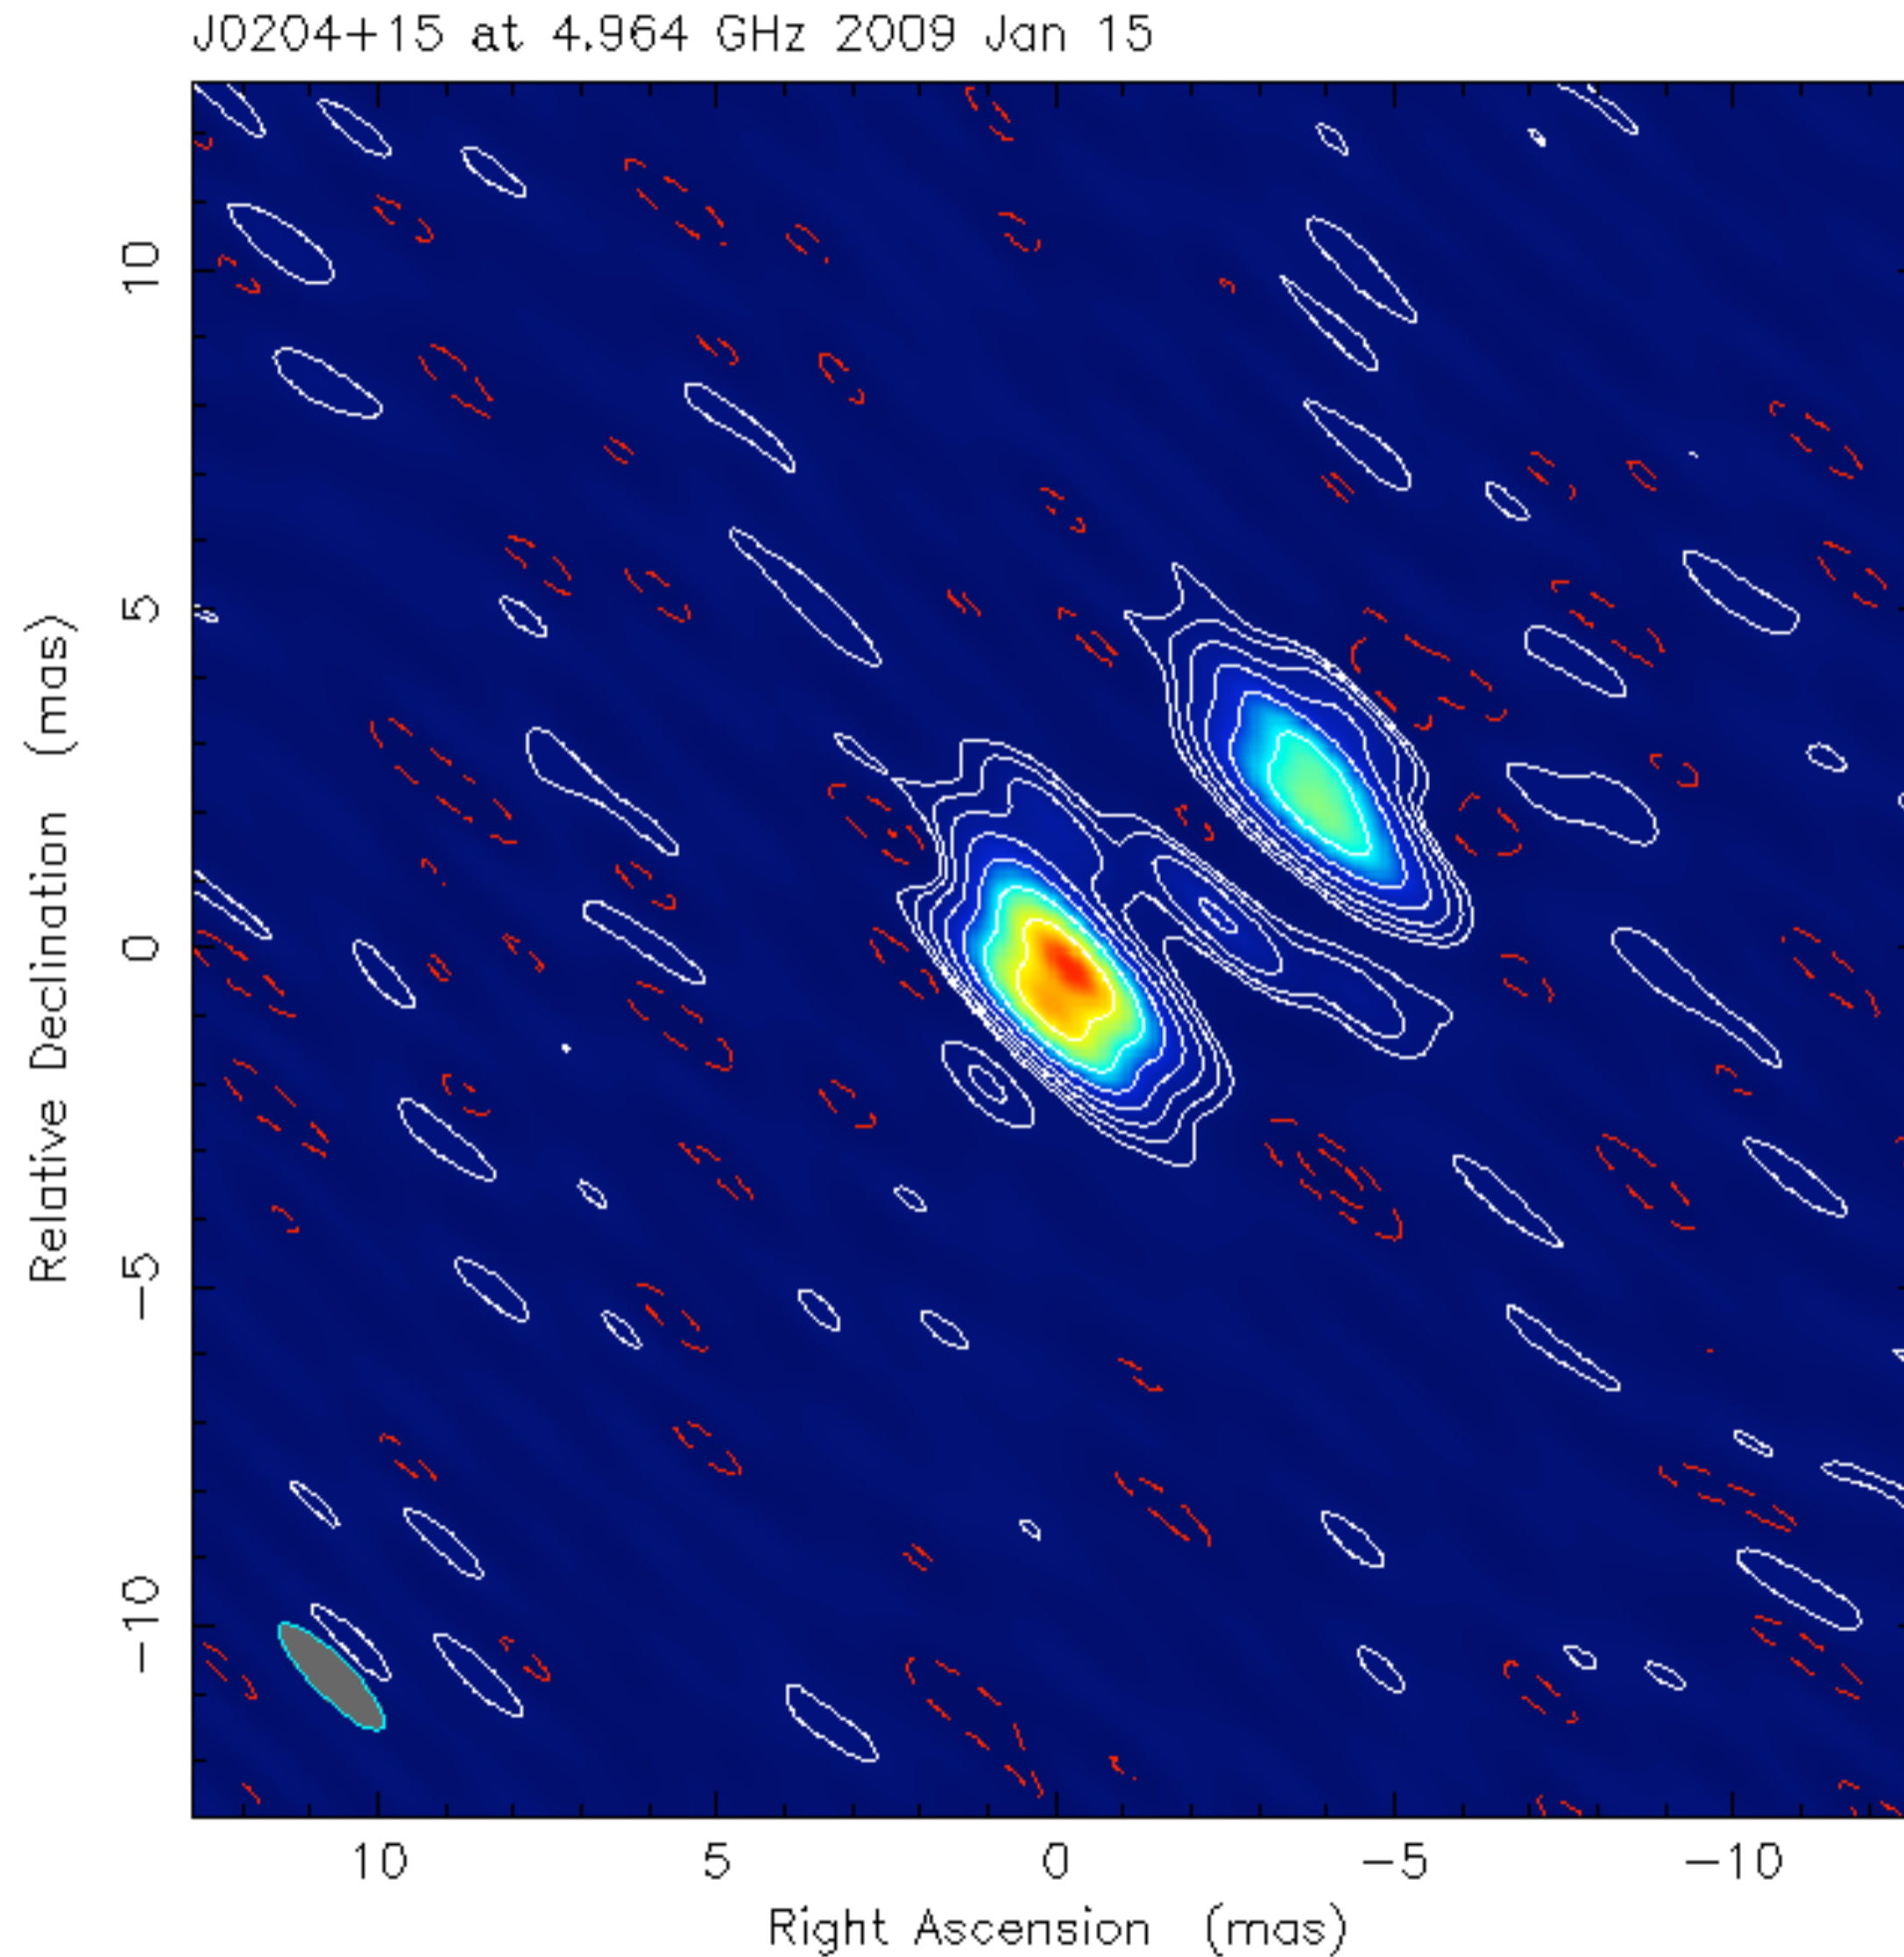

# International Year of Astronomy

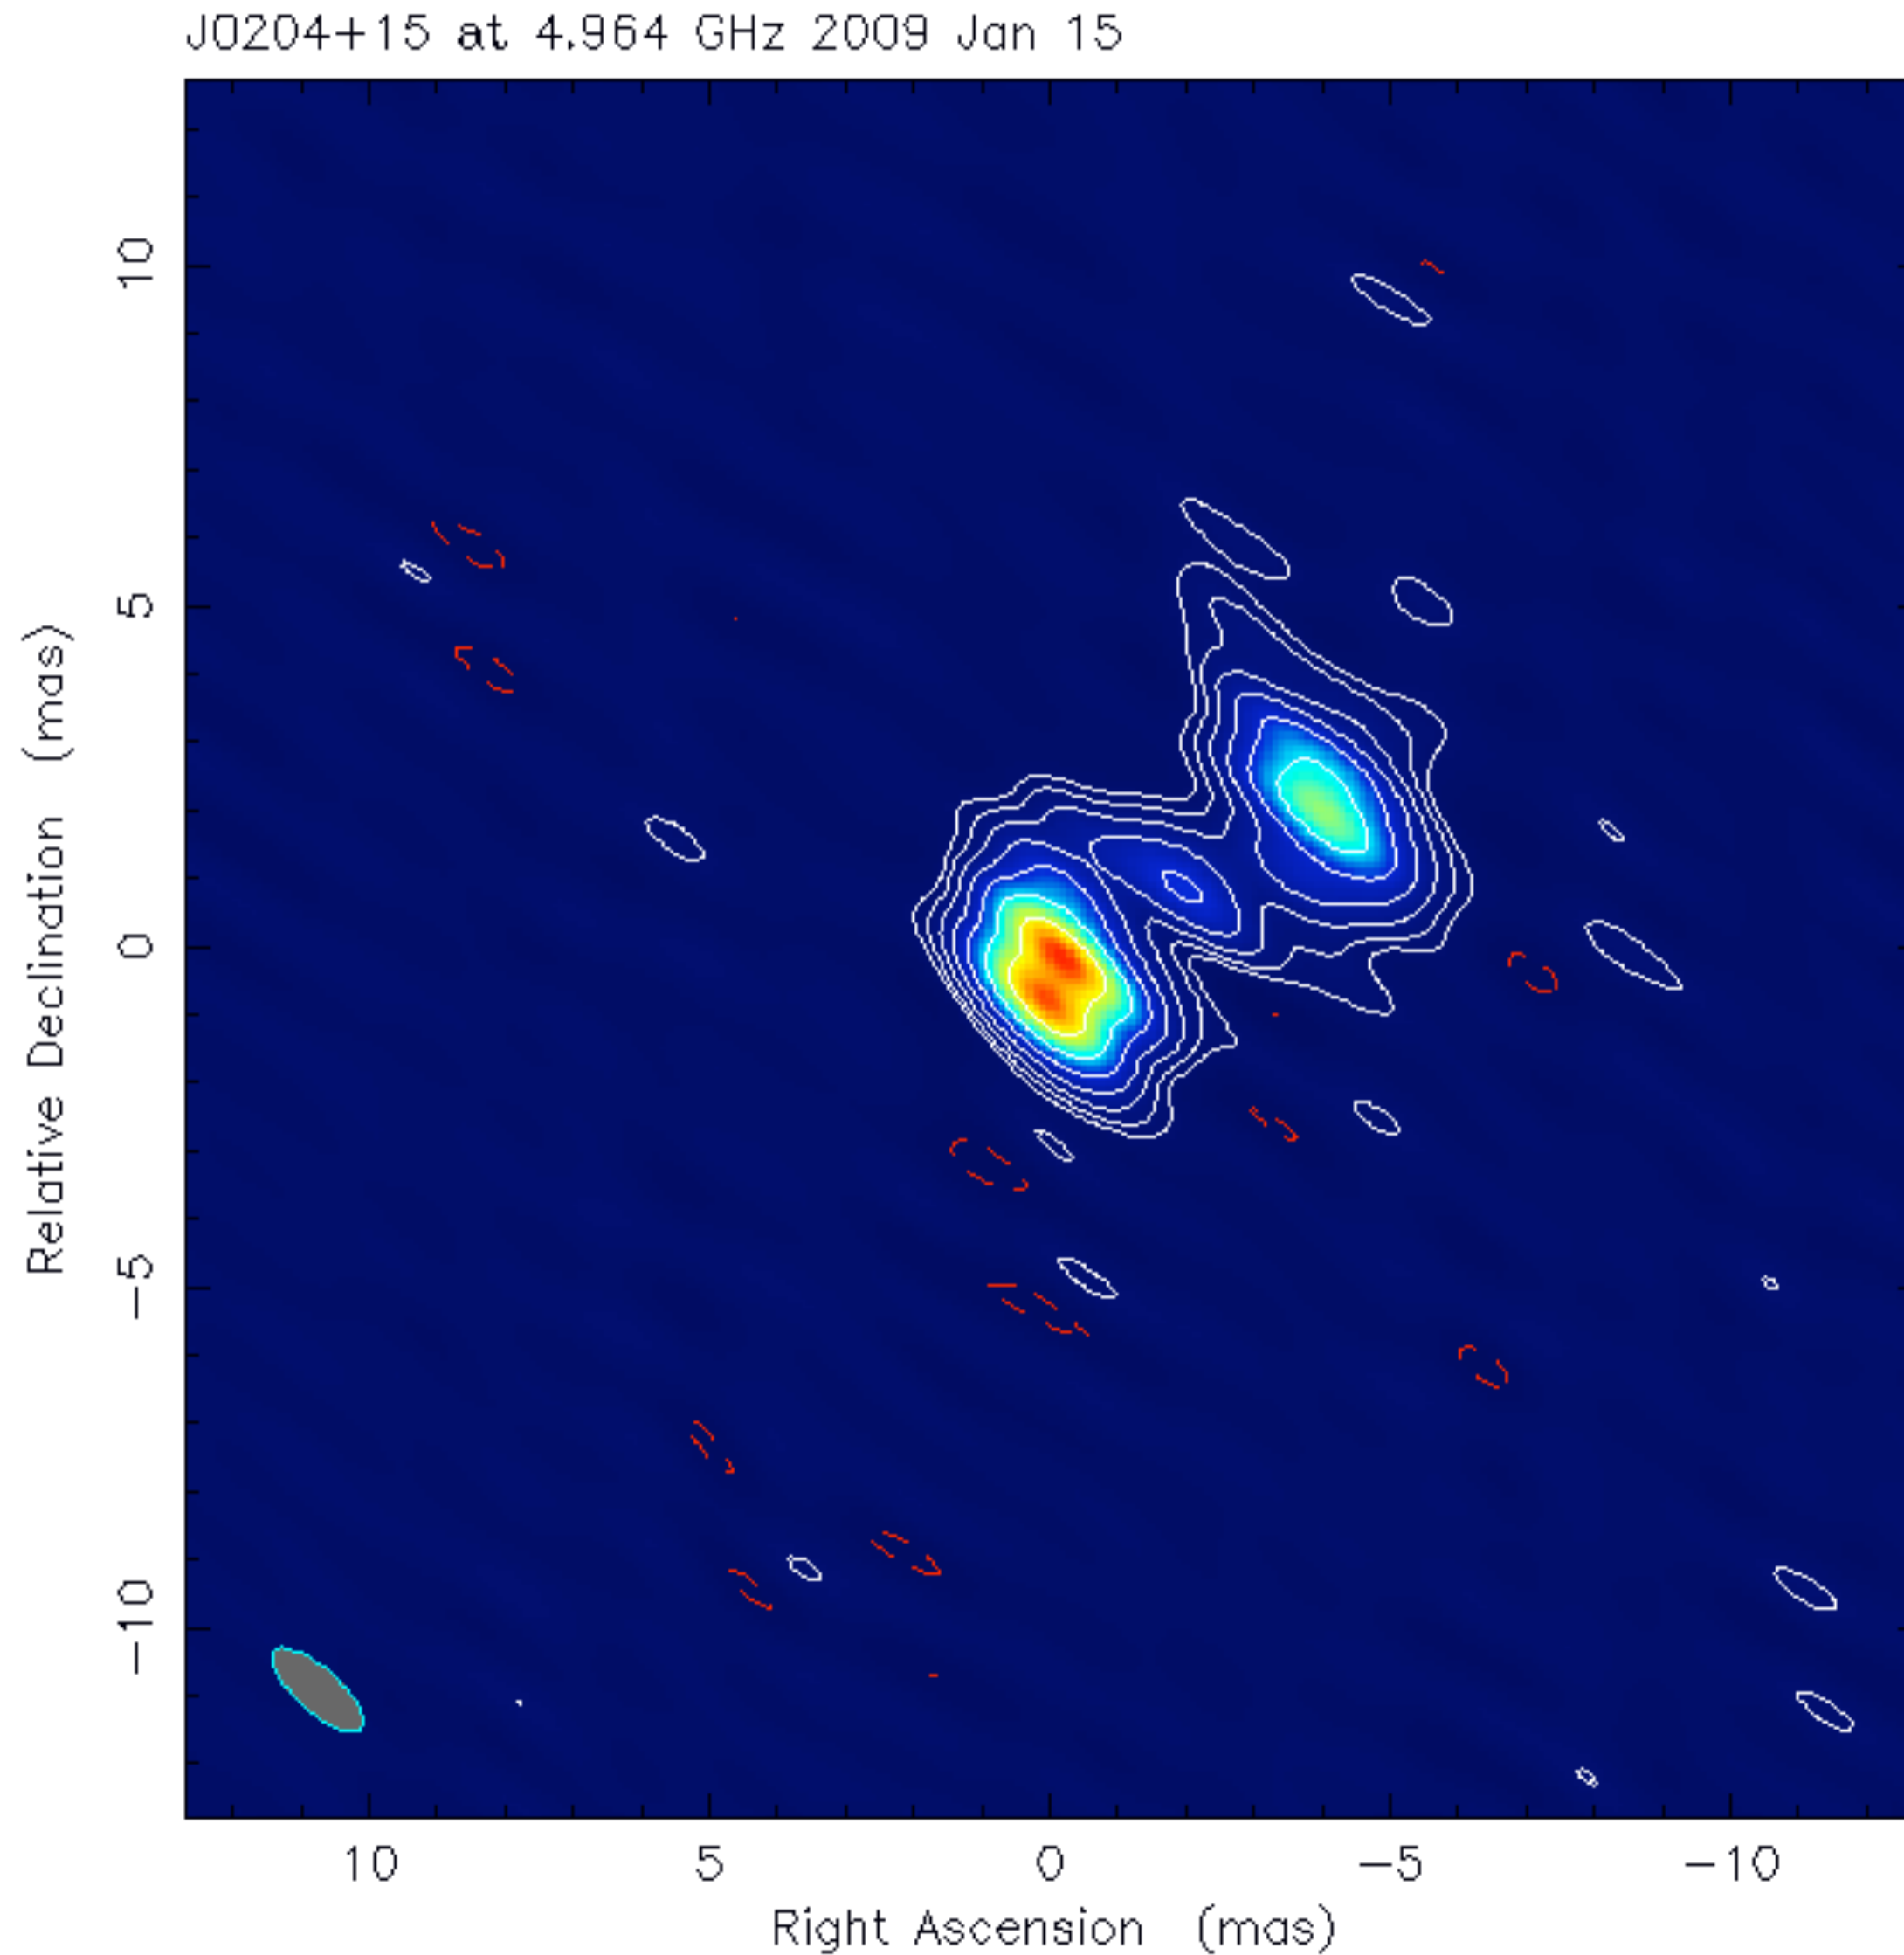

# Observation of J0204+15 (IYA)

# Observation of J0204+15 (IYA)

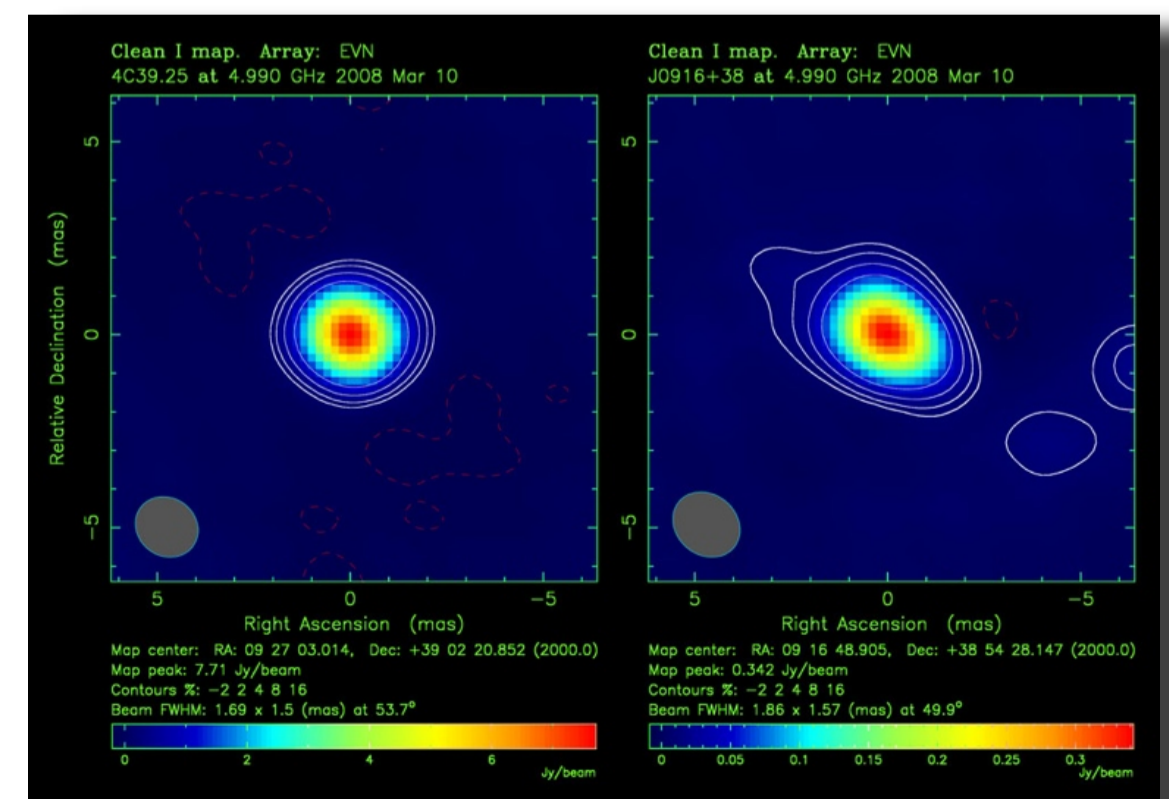

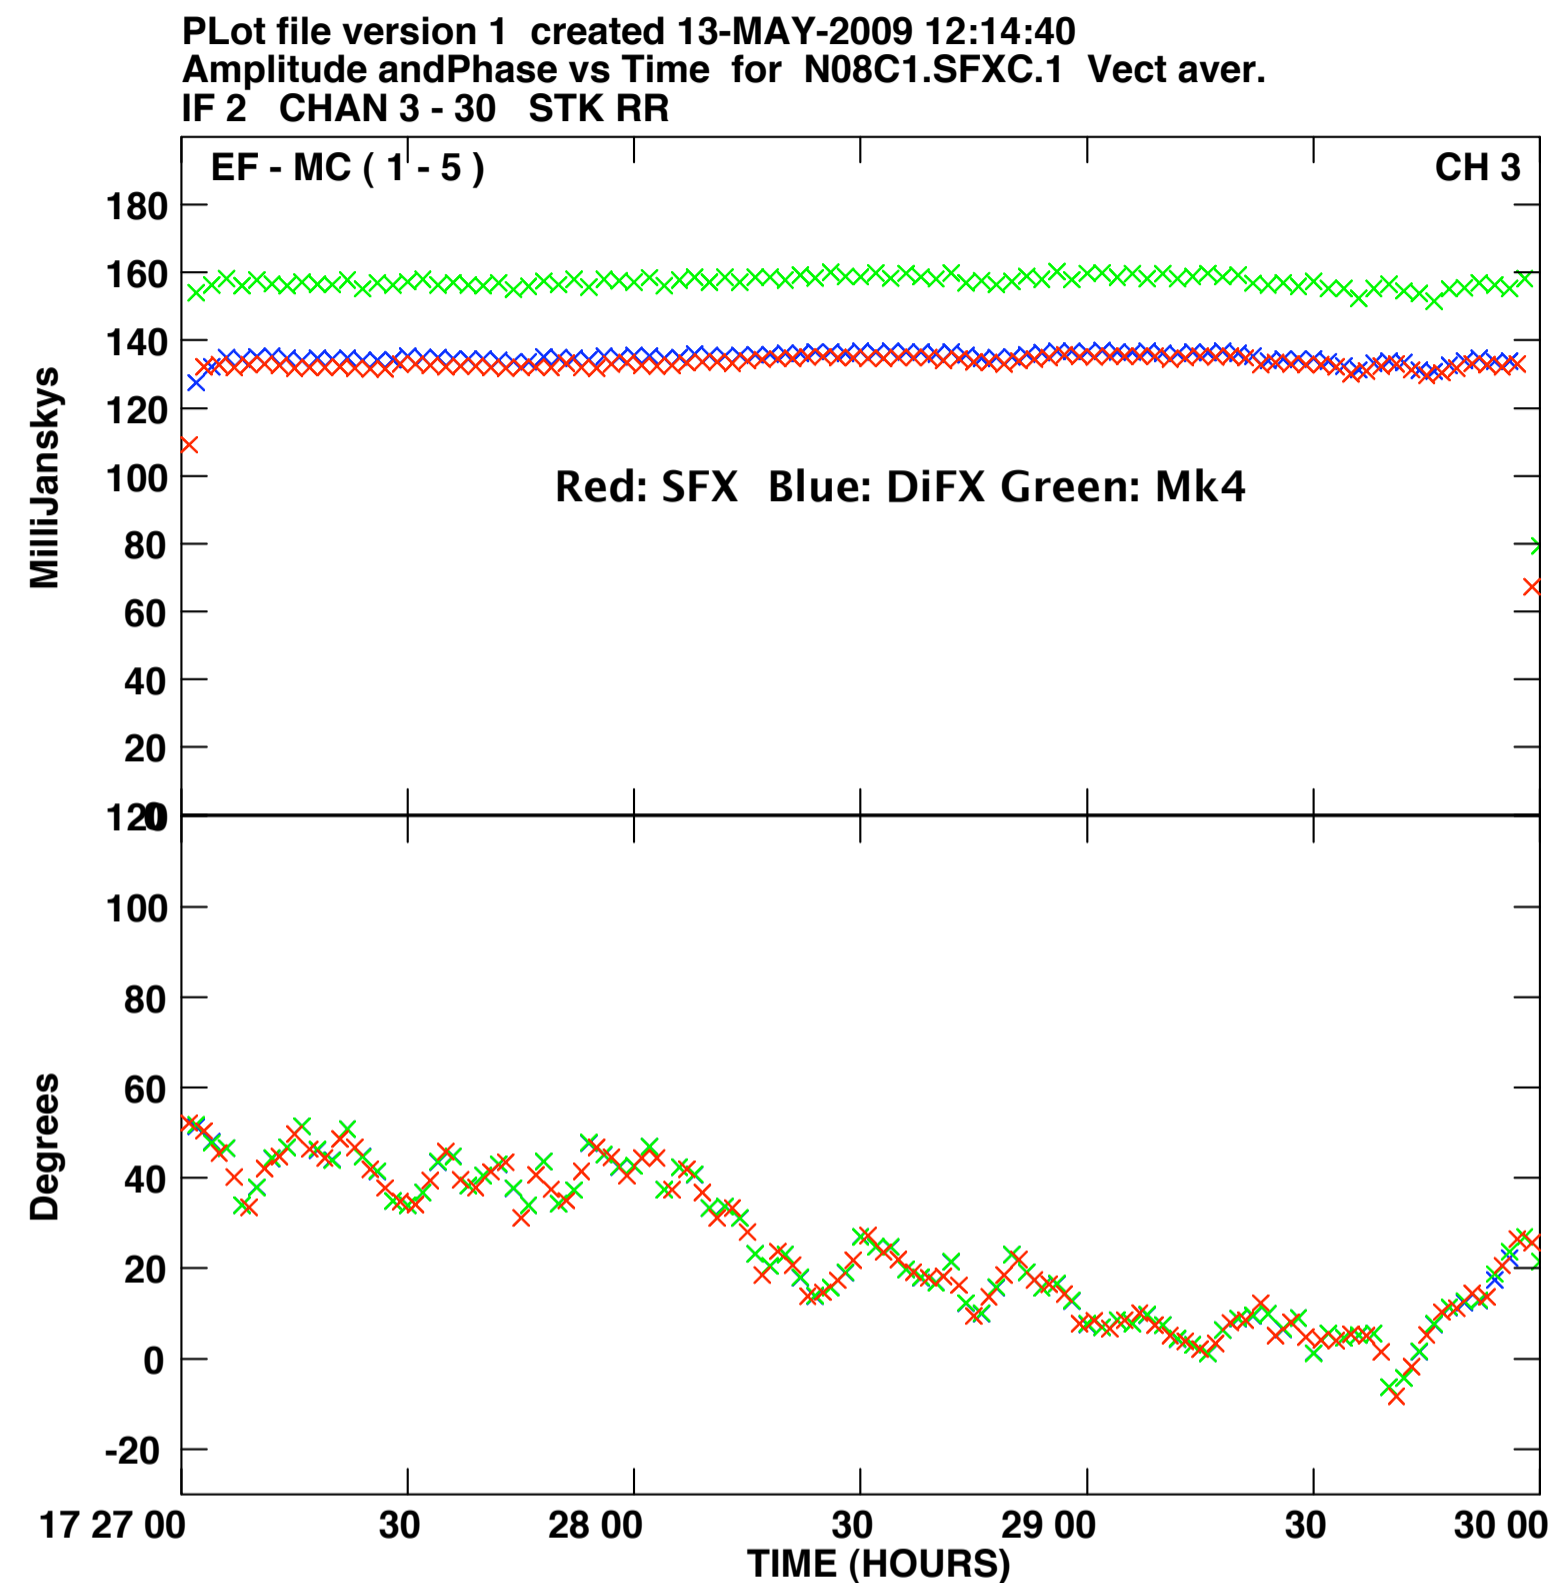

# Observation of J0204+15 (IYA)

# VLBI and Grids

- EVN correlator is hardware based
- We have also developed a software correlator:
  - Higher flexibility, frequency resolution
  - Huge computational demand
- Correlation is fairly easy to parallelise
- Low number of operations per byte, but high input data rate
- Regular 'batch'-like Grid processing (GridFTP etc.) not a good match
- Need clusters with high input connectivity
- Researching distributed correlation

# VLBI parameter space

- Resolution: depends on longest baseline, and observing frequency
- Sensitivity: depends on  $\sqrt{\text{Bandwidth}}$ , number and size of radio telescopes
- Current EVN correlator limitations:  
16 stations @ 1024Mb/s each

Technological advances in e.g. A/D converters, RF technology, digital signal processing, networking and HPC can now enable much increased sensitivity

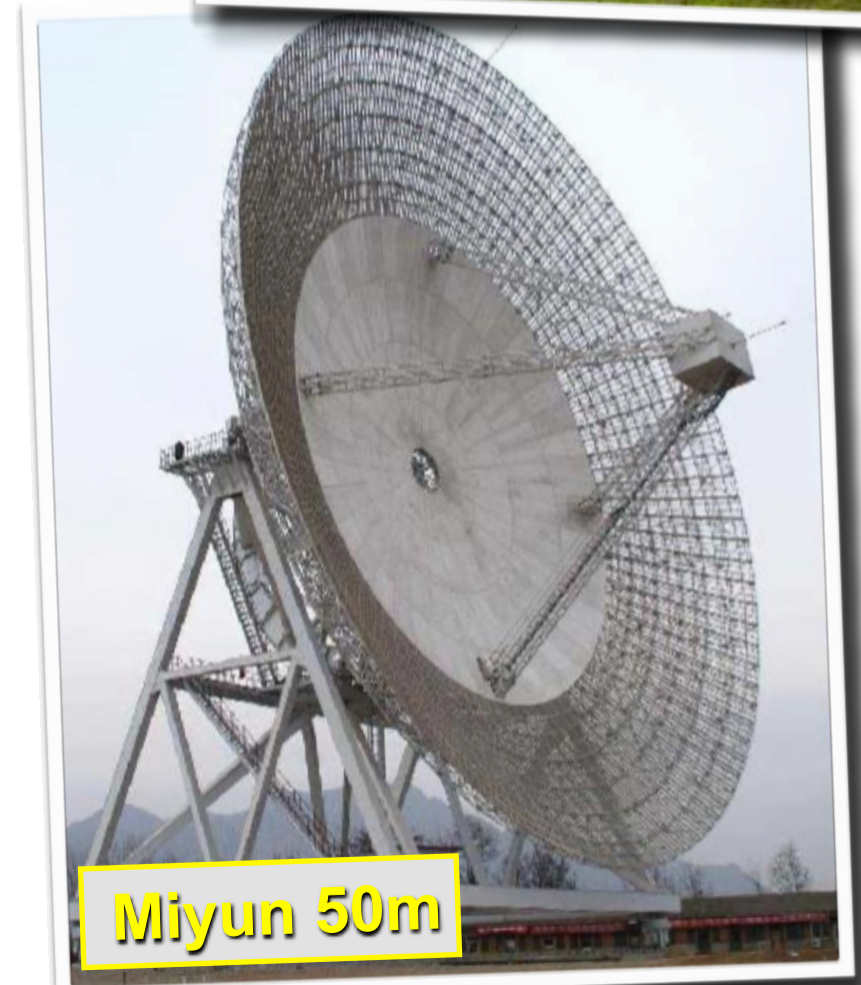

# The Uniboard project

- Collaboration of European & Korean Astronomical Institutes
- Reconfigurable FPGA-based platform for astronomical signal processing
- Digital back-end, pulsar timing, RFI mitigation, beam-forming, correlation
- Standardized on Ethernet 10Gb/s connections
- First hardware in December

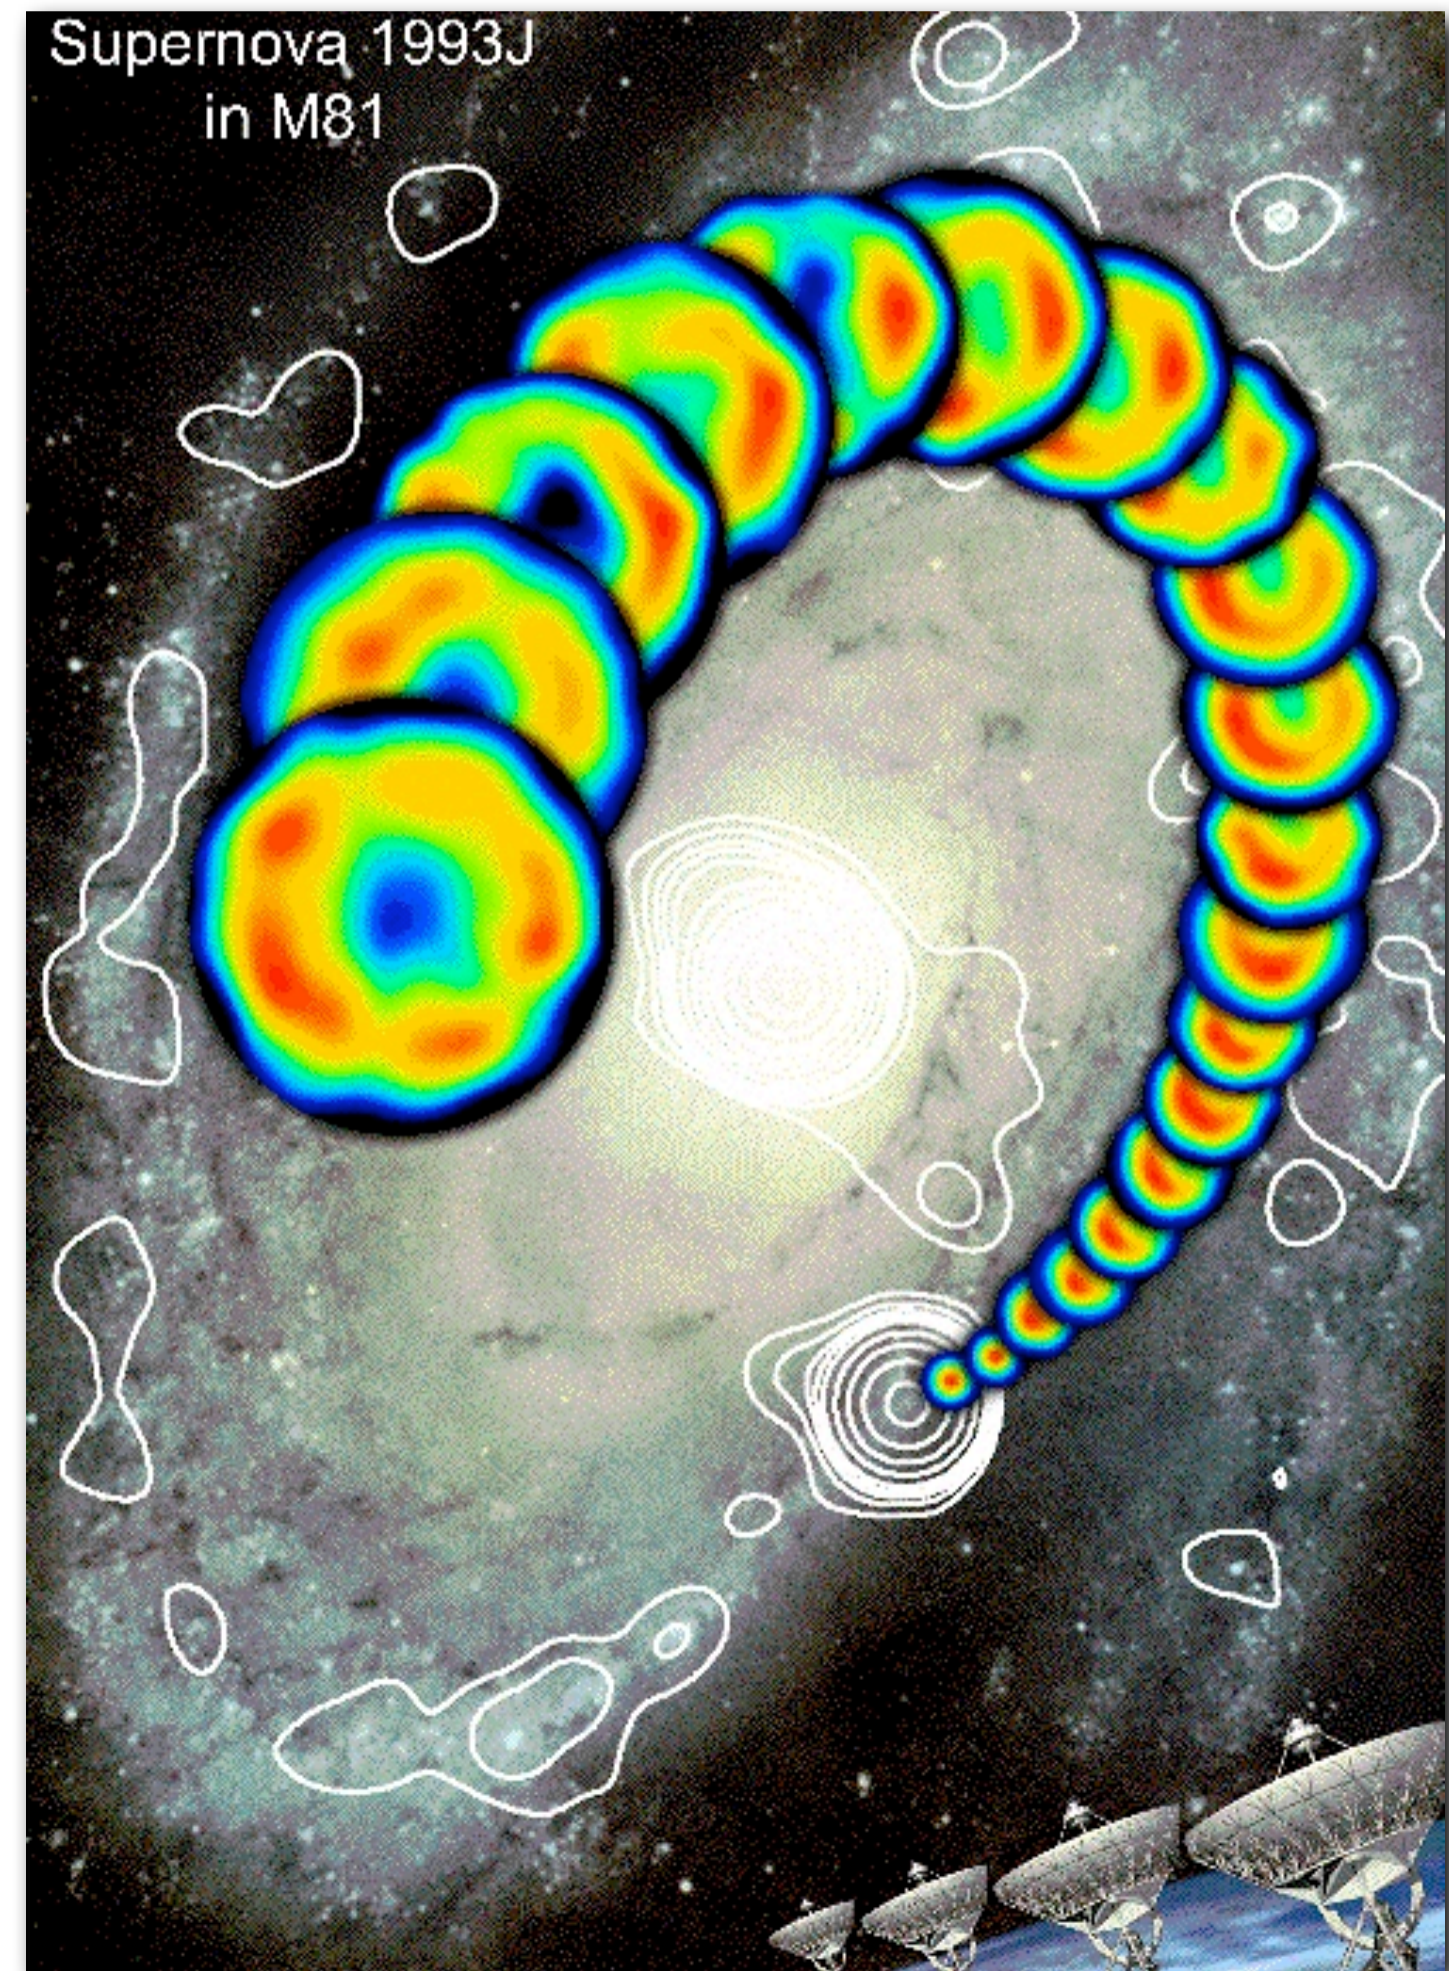

UNIBOARD  
Size: 9HE (366,7)x 280 x 2.4mm

# New telescopes

# The future of VLBI

- All VLBI can be e-VLBI !
- Caching when necessary (outages, lack of bandwidth)
- Real-time correlation is a great diagnostic tool
- Much higher bandwidths per telescope
  - 4 Gb/s soon, 10 Gb/s, how about 64Gb/s ?
- More telescopes, global array
- New correlators (hardware, software)

Questions?
