## Summary

Phase Evolution

## Why we are not satisfied with kinetics or hybrid models?

- Only crossover transition into QGP is accessible in kinetics  
A Multi-Phase Transport (AMPT) model [Lin, Ko and Pal, PRL 89, 152301 (2002)]  
Parton-Hadron-String Dynamics [Cassing, Bratkovskaya, arXiv:0907.5331 (2009)]
- In hybrid models (Kinetics-Hydro-Kinetics), transition into QGP is inaccessible at the early (nonequilibrium) stage of the collision

## 3-Fluid Hydrodynamics

- directly addresses **Equation of State (EoS)**!
- **1st-order phase transition into QGP** is accessible through EoS
- **Transition into QGP** is accessible also **at the early (nonequilibrium) stage** of the collision
- However, all this requires certain approximations

# 3FH Assumption

Femtoscopia results

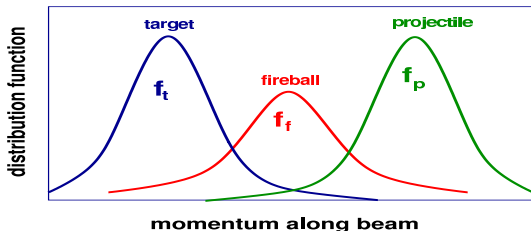

## Summary

Phase Evolution

- Distributions are separated in momentum space  
⇒ different fluids
- Leading particles carry baryon charge  
⇒ 2 baryon-rich fluids: **projectile-like** and **target-like**

At high incident energies ( $E_{lab} \gtrsim 10A$  GeV)

- Produced particles populate mid-rapidity ⇒ **fireball fluid**

This a minimal extension of hydrodynamics required by heavy-ion dynamics

## Summary

Phase Evolution

Produced particles populate mid-rapidity  
 $\Rightarrow$  fireball fluid

**Target-like fluid:**

$$\partial_\mu J_t^\mu = 0$$

Leading particles carry bar. charge

$$\partial_\mu T_t^{\mu\nu} = -F_{tp}^\nu + F_{ft}^\nu$$

exchange/emission

**Projectile-like fluid:**

$$\partial_\mu J_p^\mu = 0,$$

$$\partial_\mu T_p^{\mu\nu} = -F_{pt}^\nu + F_{fp}^\nu$$

**Fireball fluid:**

$$J_f^\mu = 0,$$

Baryon-free fluid

$$\partial_\mu T_f^{\mu\nu} = F_{pt}^\nu + F_{tp}^\nu - F_{fp}^\nu - F_{ft}^\nu$$

Source term

Exchange

The source term is delayed due to a formation time  $\tau$

**Total energy-momentum conservation:**

$$\partial_\mu (T_p^{\mu\nu} + T_t^{\mu\nu} + T_f^{\mu\nu}) = 0$$

## Summary

Phase Evolution

## II. Friction was fitted to reproduce the baryon stopping

- **Hadronic EoS**

Friction in hadronic phase was estimated by Satarov (SJNP 1990)

This friction had to be enhanced.

- **2-phase EoS and crossover EoS**

Phenomenological friction in QGP phase.

**Advantage of deconfinement scenarios:**

Satarov's friction in hadronic phase needs no modification

## III. Freeze-out

When system becomes dilute, hydro has to be stopped

Freeze-out energy density  $\varepsilon_{frz} = 0.4 \text{ GeV}/\text{fm}^3$

Summary

Phase Evolution

baryon density ( $n_B/n_0$ ) in reaction plane of Au+Au collision at  $\sqrt{s_{NN}} = 6.4$  GeV,  $b = 6$  fm

## Output at the freeze-out stage

All fluids are frozen out in small droplets characterized by

- proper volume  $V^{\text{pr}}$ ,
- temperature  $T$ ,
- baryon,  $\mu_B$ , and strange,  $\mu_S$ , chemical potentials
- collective flow velocity  $u^\mu$ ,

$T$ ,  $\mu_B$  and  $\mu_S$

are determined from

baryon  $\rho_B$ , strangeness  $\rho_S$  and energy  $\varepsilon$  densities  
using hadronic-gas EoS.

# 3FH observables

## 3FH model

ICNFP 2017

Hadron phase space distributions,

$$p^{*0} \frac{d^3 N_i}{d^3 \mathbf{p}^*} = \sum_{\alpha} \frac{g_i V_{\alpha}^{\text{pr}}}{(2\pi)^3} \frac{p^{*0}}{\exp [(p^{*0} - \mu_{\alpha i})/T_{\alpha}] \pm 1}$$

$\mu_{\alpha i} = B_i \cdot \mu_{\alpha B} + S_i \cdot \mu_{\alpha S}$  is the chemical potential of hadron  $i$  with baryon number  $B_i$  and strangeness  $S_i$ ,

$\alpha$  summation runs over droplets from all (p, t and f) fluids,

\* denotes momentum in the droplet rest frame.

Observables are integrals of distribution functions

$$\text{directed flow} = v_1(y) = \int d^2 p_T (p_x/p_T) (p^{*0} d^3 N/d^3 p^*) / (d^3 N/dy)$$

## Summary

$$\text{rapidity distribution} = dN/dy = \int d^2 p_T p^{*0} d^3 N/d^3 p^*$$

Summary

Phase Evolution

In order to use the 3FH as an event generator, the output should be in terms of observed particles.

Monte Carlo sampling procedure:

Hadrons are sampled according to their phase space distributions,

$$p^{*0} \frac{d^3 N_i}{d^3 \mathbf{p}^*} = \sum_{\alpha} \frac{g_i V_{\alpha}^{\text{pr}}}{(2\pi)^3} \frac{p^{*0}}{\exp[(p^{*0} - \mu_{\alpha i})/T_{\alpha}] \pm 1}$$

\* denotes momentum in the droplet rest frame

$\mu_{\alpha i} = B_i \cdot \mu_{\alpha B} + S_i \cdot \mu_{\alpha S}$  is the chemical potential of hadron  $i$  with baryon number  $B_i$  and strangeness  $S_i$ ,

$\alpha$  summation runs over droplets from all (p, t and f) fluids.

Summary

Phase Evolution

## The sampling is runs as a loop over all droplets:

- average multiplicities of all hadron species are calculated according to

$$\Delta N_{i,\alpha} = V_{\alpha}^{\text{pr}} n_{i,\text{th}}(T, \mu_i),$$

together with their sum  $\Delta N_{\text{tot},\alpha} = \sum_j \Delta N_{j,\alpha}$ ;

- total (integer) number of hadrons from each droplet is sampled according to Poisson distribution with mean  $\Delta N_{\text{tot},\alpha}$ .  
If the number is greater than zero, sort of hadron is randomly chosen based on probabilities  $\Delta N_{i,\alpha} / \Delta N_{\text{tot},\alpha}$ ;
- hadron's momentum  $p^*$  is sampled according to its phase space distribution, which is isotropic in momentum space;
- momentum is Lorentz boosted to the global frame of the collision.

Particle multiplicities fluctuate from event to event according to the composition of grand canonical ensembles.
