Introduction to MAGNETS I

Davide Tommasini

Introduction to Magnets: Outline

Organization of the magnet week

Part I : Introductory concepts

Part II: Theoretical foundations

Fundamentals I : Maxwell
Fundamentals II : Field Harmonics

Organization of the Magnets Week

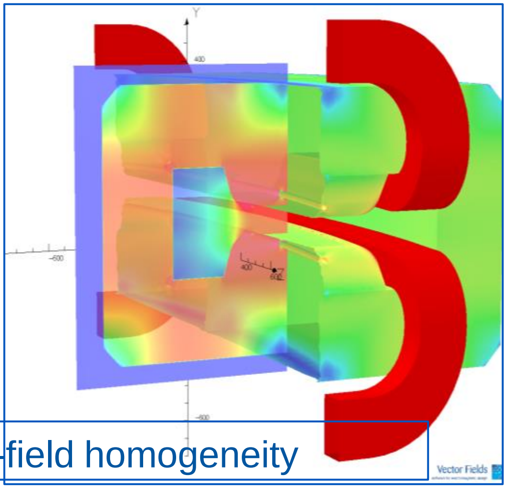
juas...

WEEK 8

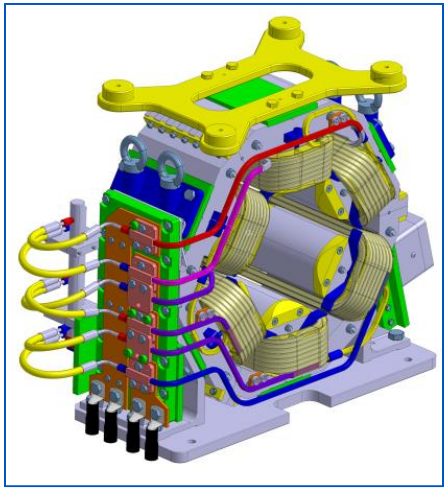
Schedule 2017	Monday Feb 27th	Tuesday Feb 28th	Wednesday March 1st	Thursday March 2nd	Friday March 3rd
09:00	**Introduction to Magnets I** lecture *D. Tommasini*	**Superconducting magnets** lecture *M. Wilson / P. Ferracin*	**Mini-workshop** **Normal conducting Magnets** *J. Bauche & T. Zickler*	***Bus leaves at 8:00 from JUAS*** *(Lunch at CERN, offered by ESI)* **PRACTICAL WORKS AT CERN** RF coordinator: **F. Caspers** VACUUM coordinator: **P. Chiggiato** MAGNETS coordinator: **J. Bauché** SUPERCONDUCTIVITY coordinator: **J. Fleiter** ***Bus leaves at 17:30 from CERN***	***Bus leaves at 8:00 from JUAS*** *(Lunch at CERN, offered by ESI)* **PRACTICAL WORKS AT CERN** RF coordinator: **F. Caspers** VACUUM coordinator: **P. Chiggiato** MAGNETS coordinator: **J. Bauché** SUPERCONDUCTIVITY coordinator: **J. Fleiter** ***Bus leaves at 17:30 from CERN***
10:00	**Introduction to Magnets II** lecture *D. Tommasini*	**Coffee Break**	**Coffee Break**		
10:15		**Superconducting magnets** lecture *M. Wilson / P. Ferracin*	**Mini-workshop** **Normal conducting Magnets** *J. Bauche & T. Zickler*		
10:30	**Coffee Break**				
	10:45 **Normal Conducting magnets** lecture *T. Zickler*				
11:15		**Superconducting magnets: cryogenics** lecture *Ph. Lebrun*	**Mini-workshop** **Normal conducting Magnets** *J. Bauche & T. Zickler*		
12:15	**WELCOME LUNCH OFFERED BY ESI**	**BREAK**	**BREAK**		
14:00	**Superconducting magnets** lecture *M. Wilson / P. Ferracin*	**Superconducting magnets** lecture *M. Wilson / P. Ferracin*	**Mini-workshop** **Superconducting Magnets** *M. Wilson & P. Ferracin & D. Schoerling*		
15:00	**Superconducting magnets** lecture *M. Wilson / P. Ferracin*	**Normal Conducting magnets** lecture - *T. Zickler*	**Mini-workshop** **Superconducting Magnets** *M. Wilson & P. Ferracin & D. Schoerling*		
16:00	**Coffee Break**	**Coffee Break**	**Coffee Break**		
16:15	**Normal Conducting magnets** lecture - *T. Zickler*	**Normal Conducting magnets** lecture - *T. Zickler*	**Mini-workshop** **Superconducting Magnets** *M. Wilson & P. Ferracin & D. Schoerling*		
17:15	**Normal Conducting magnets** lecture - *T. Zickler*	**Normal Conducting magnets** lecture - *T. Zickler*			
18:15					

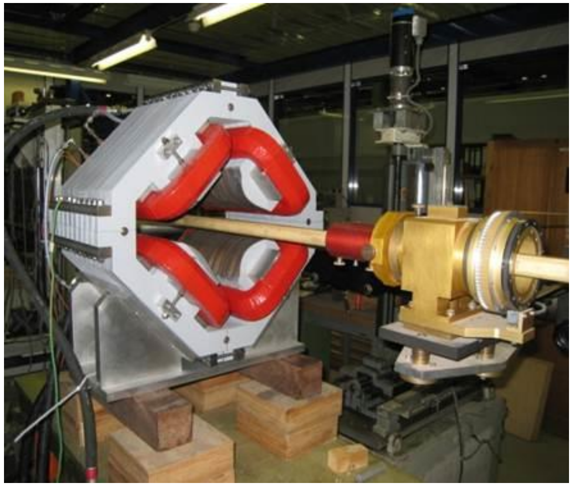
Normal-conducting accelerator magnets

How to design an accelerator magnet, with “real” examples



3D-field homogeneity

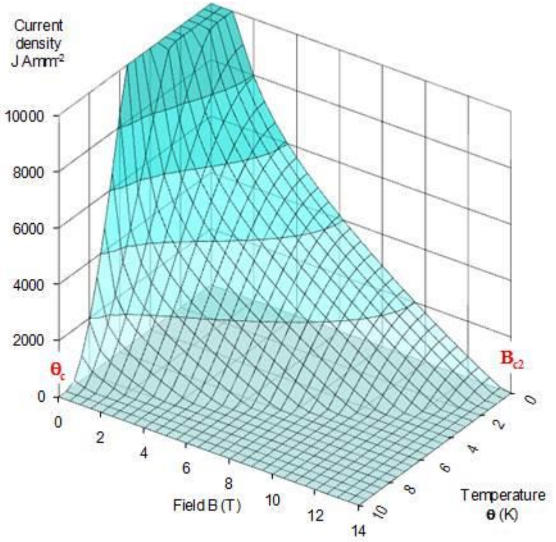


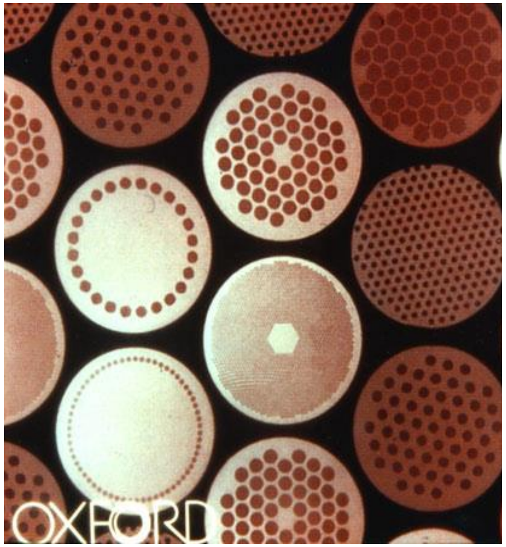


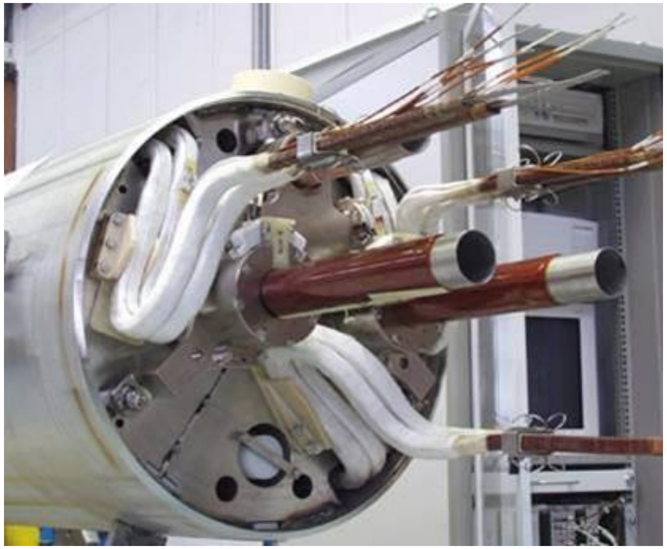
Superconducting Accelerator Magnets

Properties and behaviour of superconductors

Use of superconductors in magnets

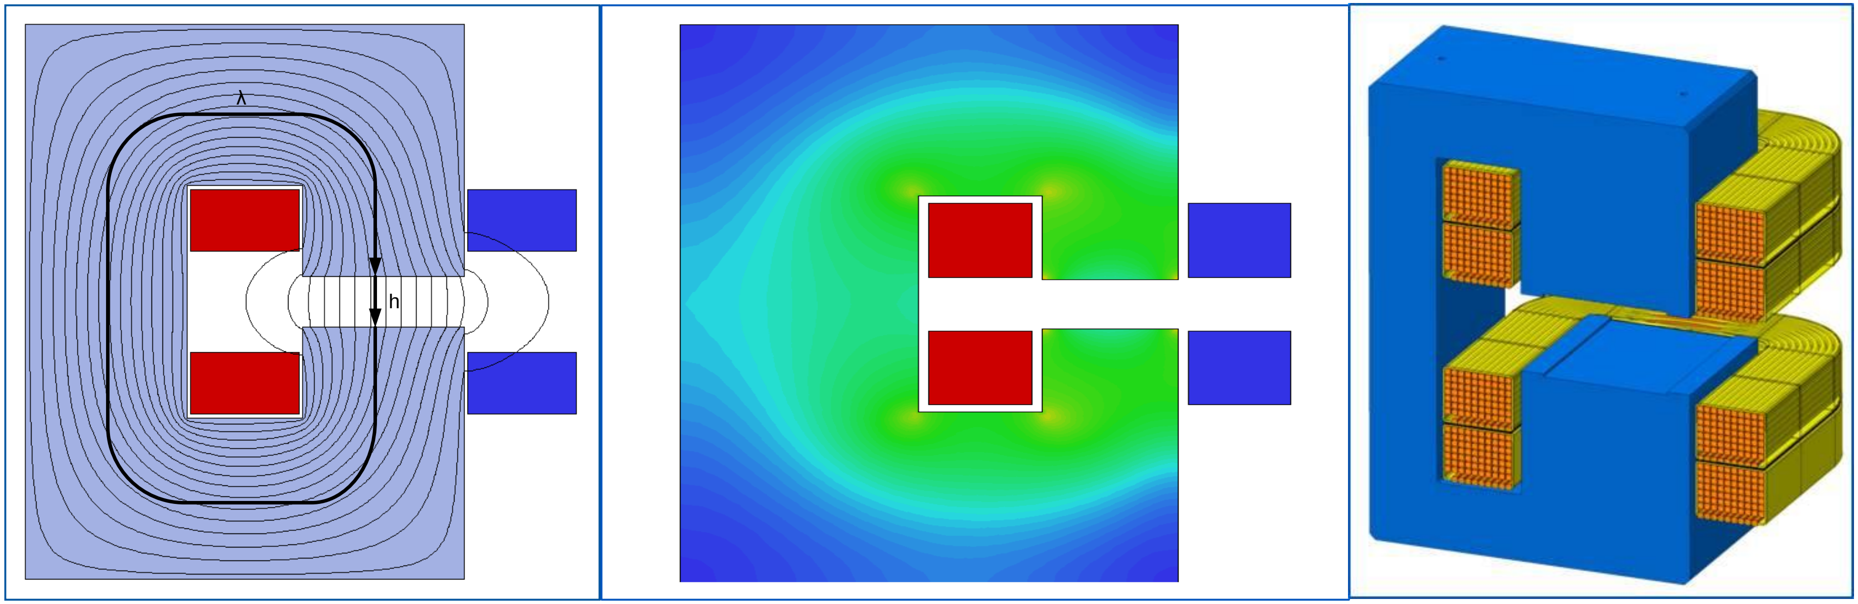






Mini-workshop on normal conducting magnets

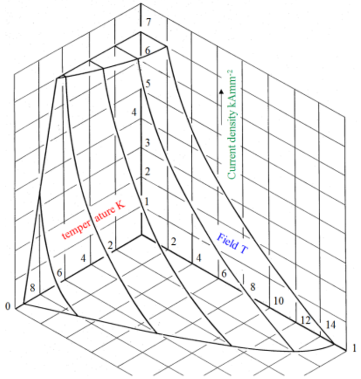
- Goal: outline design of a normal conducting magnet



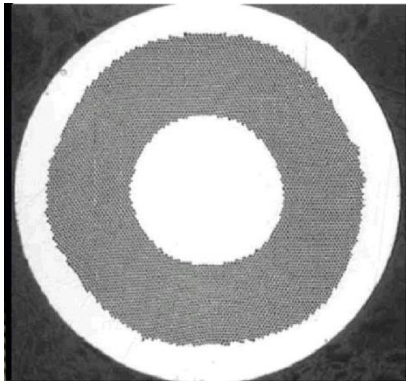
Mini-workshop on superconducting magnets

- Goal: outline design of a super-conducting magnet

Superconducting material



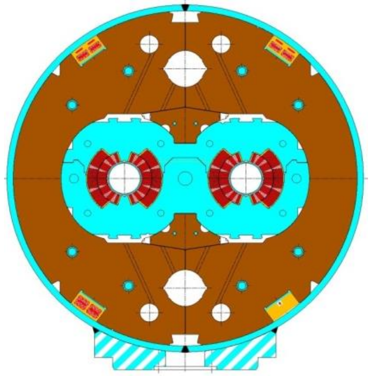
Superconducting strand



Superconducting cable

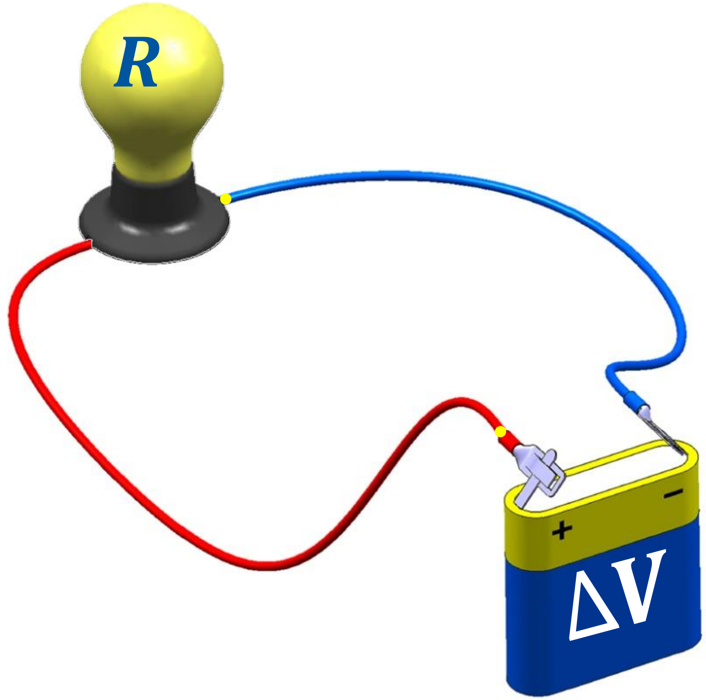
Superconducting coil

Superconducting magnet



Introductory concepts

Electricity

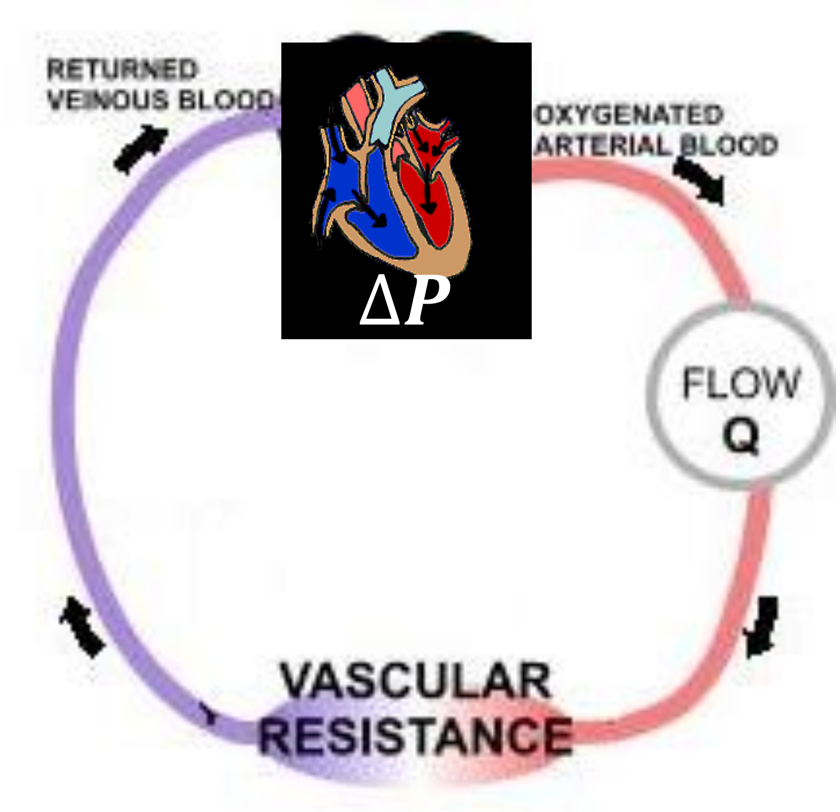


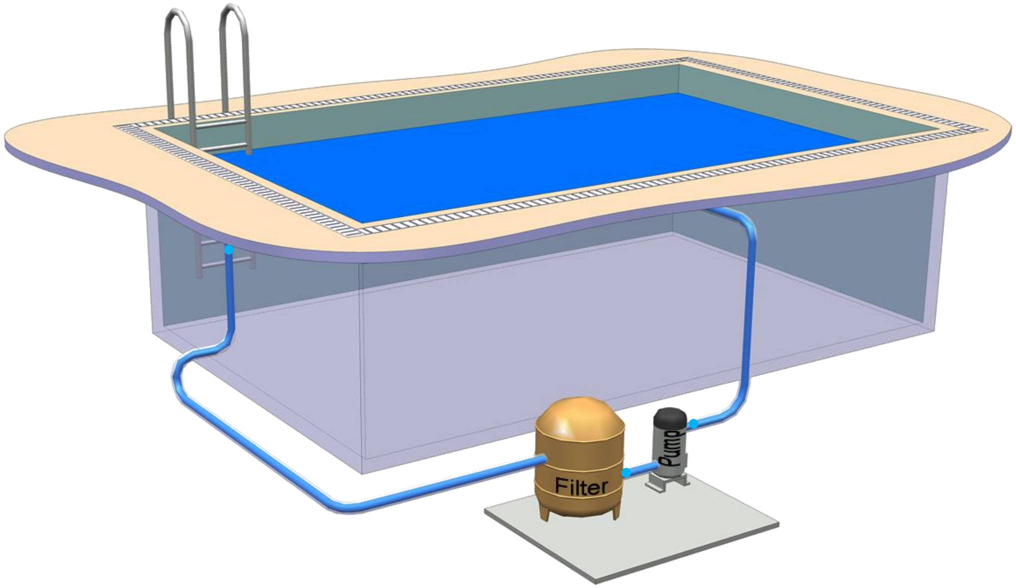
$$\frac{\Delta V}{\Delta l} = \rho \cdot J$$

electric strength
produces a ***J***

$$J \cdot S = I = \Delta V / R$$

Hydraulics



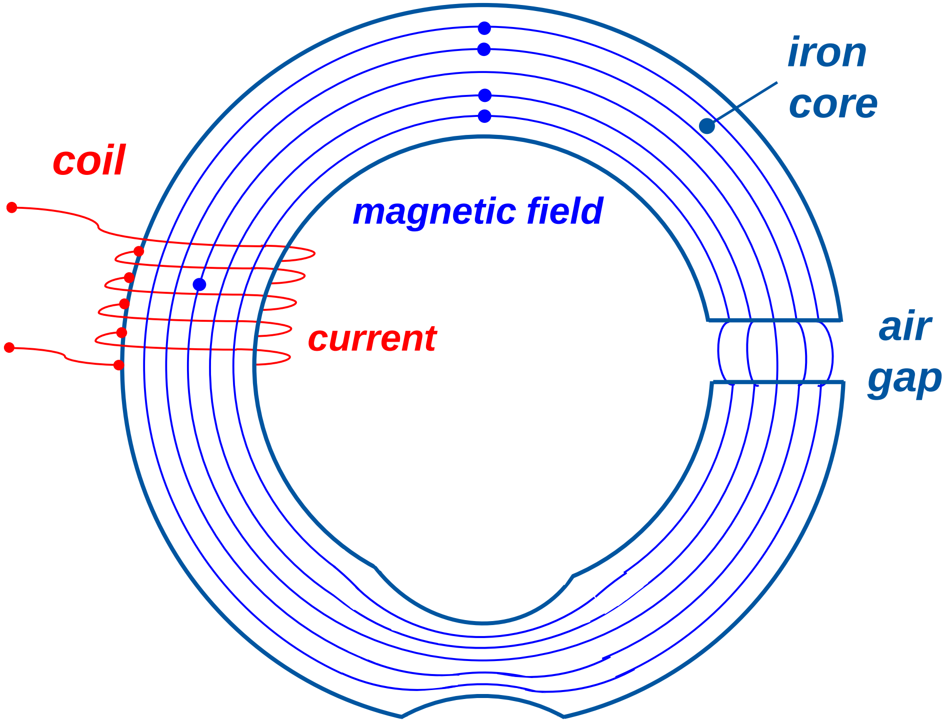


$$v \cdot S = Q = \Delta P / R$$

$$\frac{\Delta P}{\Delta l} = \lambda \cdot v$$

hydraulic strength
produces a ***v***

Magnetism



$$H = \rho \cdot B$$

magnetic strength
produces a ***B***

$$B \cdot S = \varphi = NI/R = \frac{1}{R}\oint H \cdot dl$$

NI= «magnetomotive force»

B & H

In a given material, a

magnetic field strength ***H***

produces a

magnetic field induction ***B***

according to

$$\boldsymbol{B} = \mu_0 \cdot \mu_r \cdot \boldsymbol{H}$$

Inductance

The inductance is the equivalent of the inertia.

A large inertia (***I***)/inductance (***L***) means you need:

- a large force to suddenly increase the speed
- a large voltage to suddenly increase the current/field

✓ you can store energy in a wheel rotating at speed $\boldsymbol{\omega}$

✓ you can store energy in a coil supplied by a current ***i***

$$E = \frac{1}{2} I \cdot \omega^2 = \frac{1}{2} L \cdot i^2$$

When the magnetic field has to be quickly changed you want to keep the inductance low, typically by reducing the number of coil turns.

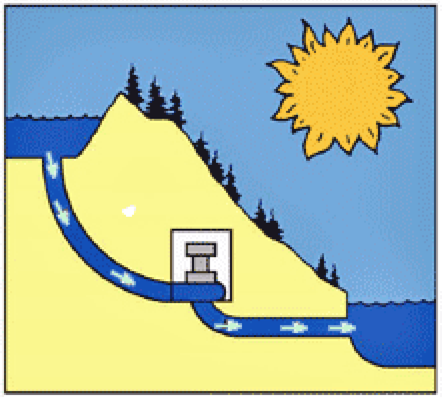
Magnetic Energy

When you fill a volume with a magnetic field you are storing a «Magnetic Energy»

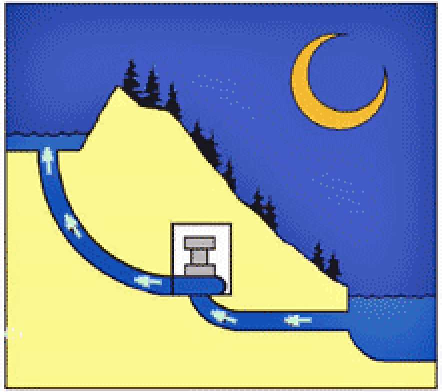
$$dE = \frac{1}{2} B \cdot H \cdot dV$$

This is the work you need to fill a volume dV with a field induction B

When you empty the volume you get back the energy, but not entirely.



Daytime: Water flows downhill through turbines, producing electricity



Nightime: Water pumped uphill to reservoir for tomorrow's use

Hysteresis

Conied in 1890 by Sir James Alfred Ewing, derived from ὑστέρησις (lack, later)

A property of a system such that an output value incorporates some lag, delay or direction/history dependence from the corresponding input (ex in regulation).

Introduction

In a hysteretic system the output not only depends on the input, but also depends on the current and previous internal states of the system. In such systems there is no way to predict their output just based on the input level. Hysteresis can be found in electrical, magnetic, mechanical, economical, and biological systems. Reports that patients awaken at lower concentration of anaesthetic than that required to put them to sleep indicate that hysteresis is an important feature of anaesthesia [1]; this clinical finding is supported by a theoretical modelling study of the induction-recovery anaesthesia cycle [3].

Hysteresis may also be an essential component of the transition between slow-wave and REM states of natural sleep [2]. Here we investigate hysteretic behavior of two classes of spiking neuron models, both individually, and as a population aggregate formed from a cluster of excitatory and inhibitory neurons.

Results

(a) Spike raster of the network in response to varying GABAA time course (1-20: inhibitory neurons, 21-100: excitatory neurons)

Model

Single neuron model
We use the simple neuron model suggested by Izhikevich [4]:

$$
\begin{aligned}
C\dot{v} &= k(v-v_r)(v-v_t) - u + I_{dc} + I_{syn} \\
\dot{u} &= a\{b(v-v_r) - u)\}
\end{aligned}
$$

$$
\text{if} \quad v \geq v_{peak}, \quad \text{then} \\
v \leftarrow c, \quad u \leftarrow u + d
$$

Arguably this is the simplest possible model capable of spiking, bursting, being an integrator or a resonator, so is recommended as the model of choice in simulations of large-scale networks of spiking neurons [4].

Parameter	Description
v	Membrane potential (mV)
u	Recovery variable
C	Membrane capacitance
v_t	Instantaneous threshold voltage
v_r	Resting potential
I_{dc}	Drive current (pA)
I_{syn}	Synaptic current (pA)
a	Decay rate of recovery variable
b	Sensitivity of recovery variable
v	Spike cutoff value (mV)

Network model
Regular spiking (RS) excitatory pyramidal neurons make up 80% of cortical neural population with the remaining the 20% being mainly fast-spiking (FS) inhibitory interneurons. The network is constructed from FS and RS neurons connected via chemical non-plastic synapses. Synaptic transmission is based on AMPA and $GABA_A$ receptors. Total synaptic current arriving at each neuron is simulated as

$$I_{syn} = g_{AMPA}(v-0) + g_{GABA_A}(v+70) + \text{noise}$$

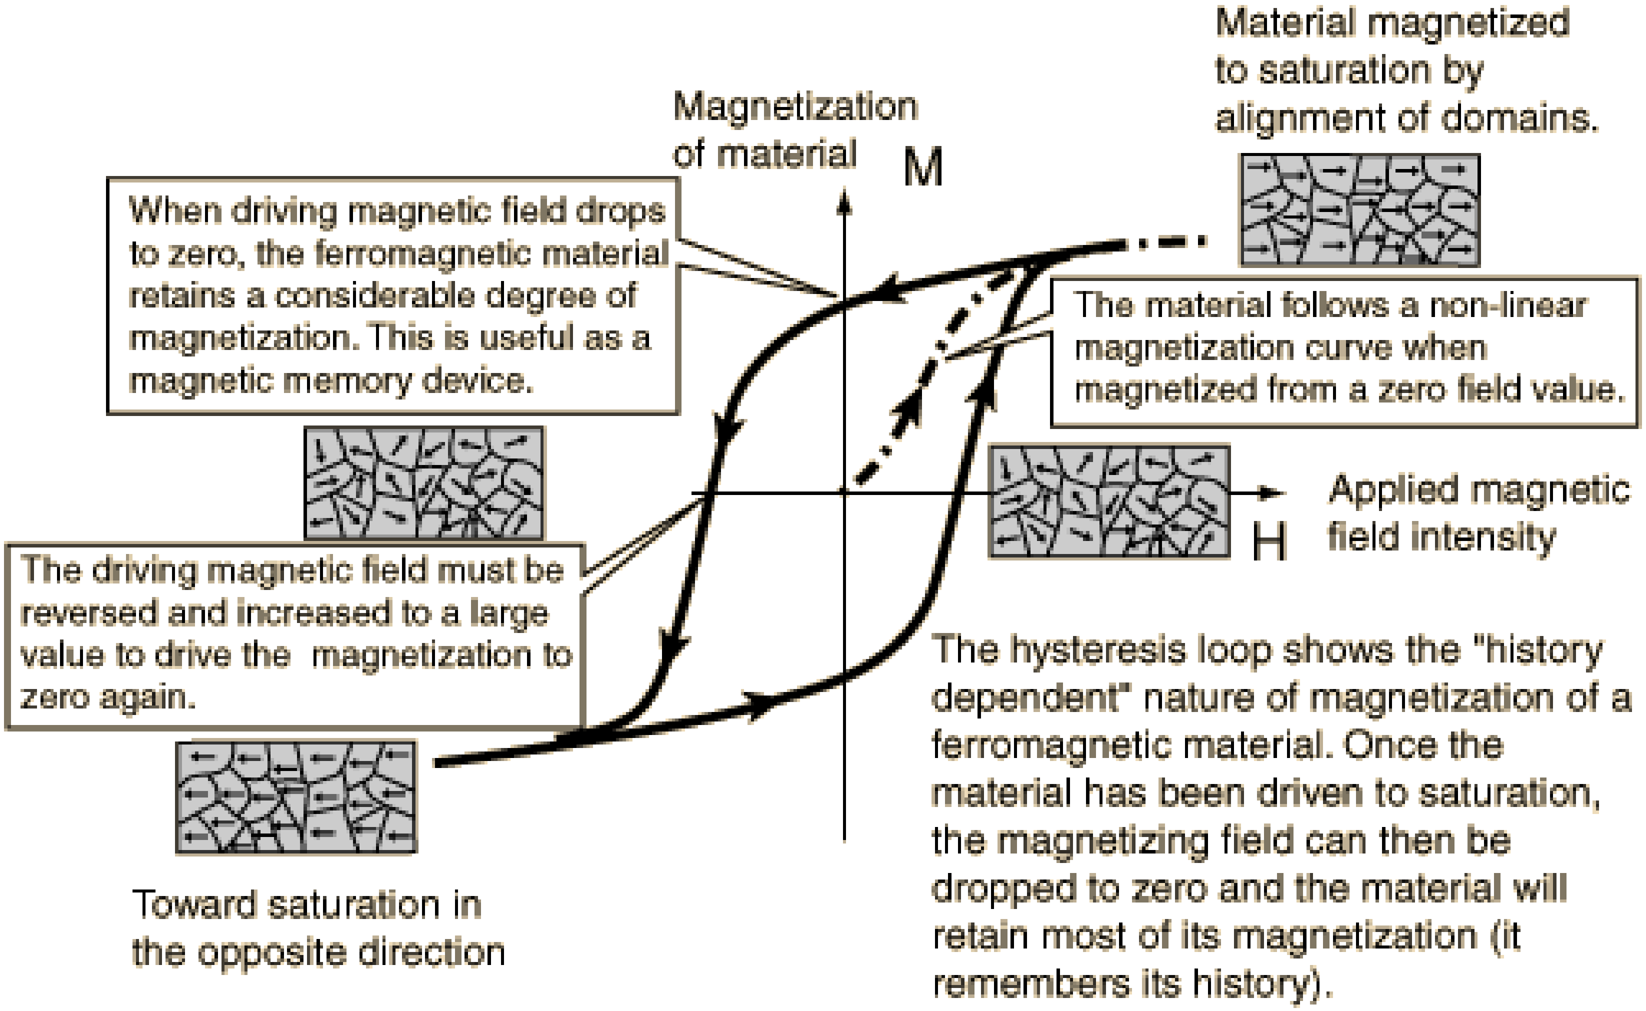
where *v* is the postsynaptic membrane potential (mV) and noise is a small amplitude white noise. Time varying conductance represents neurotransmitter release by following a simple decaying exponential form as

$$\dot{g} = \frac{-g}{\tau}$$

in which *g* is the conductance and τ is the relevant time constant.

Each RS neuron is randomly connected to 50% of the whole population and each FS neuron to 90% of the RS neurons. There is no self excitation or mutual inhibition, but all FS neurons are self inhibited. FS neurons are driven by a dc current of 70.2 pA to make them excitable: based on its phase diagram, an FS neuron will fire one spike or will be attracted to a spiral stable state. The RS neurons are in bistable regime based on the drive current of 126 pA. They can fire repetitive spikes or can be silent, attracted to a

Hysteresis



Material magnetized to saturation by alignment of domains.

When driving magnetic field drops to zero, the ferromagnetic material retains a considerable degree of magnetization. This is useful as a magnetic memory device.

The material follows a non-linear magnetization curve when magnetized from a zero field value.

The driving magnetic field must be reversed and increased to a large value to drive the magnetization to zero again.

Toward saturation in the opposite direction

The hysteresis loop shows the "history dependent" nature of magnetization of a ferromagnetic material. Once the material has been driven to saturation, the magnetizing field can then be dropped to zero and the material will retain most of its magnetization (it remembers its history).

Technologies

Permanent Magnets

The magnetic energy stored in the material is used in the magnetic circuit. This means that the magnetic field amplitude that you can produce in a given volume of air depends on:

1. the ***magnetic energy density*** that the permanent magnet material can «store»
2. the size (volume) of the permanent magnet

Electromagnets

They can be essentially:

1. normal conducting: typically ***iron dominated*** because, below ***saturation***, the ***magnetization*** ampereturns are ***cheap***
2. superconducting: more complex than normal conducting, typically used only when strictly necessary profiting that the **superconducting** ampereturns are **cheap**. Used then when the required field is above iron saturation (> 2T) or even at lower fields when the air gaps are so large that powering the required ampereturns would be non economically advantageous with respect to a normal conducting version.
