

Particle Detectors

Historic Detector: Bubble Chamber

- Invented 1952 by Donald Glaser (Noble Prize 1960)

- chamber with liquid (e.g. H_2) at boiling point (“superheated”)

- charged particles leave trails of ions

- formation of small gas bubbles around ions

- take photos of interactions and look for interesting events...

- nice pictures, but **SLOW!!!**

- only 1 photo/event every few seconds, need something faster → electronic detectors

BEBC bubble chamber

Particle Physics Methods

**Einstein
(1905):**

**Matter is
concentrated energy!**

**Matter can be transformed
into energy and back!**

$$E = m c^2$$

● We use this at a particle accelerator

- protons are accelerated ⇒ energy
- kinetic energy is transformed into matter at the collision
- new particles are being produced (new matter)

The Perfect Detector...

- ...should reconstruct any interaction of any type with 100% efficiency and unlimited resolution

→ get “4-momenta” of basic physics interaction

→ = **energy / momentum / mass + charge of ALL involved particles**

- in practice: limitations by detector inefficiency (not all particles detected) + detector resolution (measurements have statistical + systematic uncertainties)

Fixed target geometry

“Magnetic spectrometer”

- Limited solid angle $d\Omega$ coverage
- rel. easy access (cables, maintenance)

Collider geometry

“4 π multi purpose detector”

- “full” $d\Omega$ coverage
- very restricted access

High Energy Collider Detectors

- **Tracking Detector (or Tracker) = momentum measurement**
 - closest to interaction point: **vertex detector** (often silicon pixels)
 - measures primary interaction vertex and secondary vertices from decay particles
 - main or **central tracking detector**
 - measures momentum by curvature in **magnetic field** + charge of particle
- **Calorimeters = energy measurement**
 - **electro-magnetic calorimeters** (light particles: e^- , e^+ , γ)
 - measures energy of **light EM particles** (electrons, positrons, photons) based on electro-magnetic showers by bremsstrahlung and pair production
 - two concepts: homogeneous (e.g. CMS) or sampling (e.g. ATLAS)
 - **hadron calorimeters** (heavy hadronic particles: π , K, p, n)
 - measures **energy of heavy (hadronic) particles** (pions, kaons, protons, neutrons) based on nuclear showers created by nuclear interactions
- **Muon Detectors = momentum measurement for muons (more precise)**
 - outermost detector layer, **basically a tracking detector**

A typical Particle Detector

- Cut-away view of ATLAS: several layers of detectors

Detector Challenges at LHC

- **High energy collisions**
 - sufficiently **high momentum resolution** up to TeV scale
- **High luminosity (high interaction rate)**
 - **high rate** capabilities, **fast** detectors (25 ns bunch crossing rate)
- **High particle density**
 - **high granularity**, sufficiently **small detector elements** to resolve particles
- **High radiation (lots of strongly interacting particles)**
 - radiation mainly due to particles emerging from collisions, not machine background
 - **radiation-hard detectors** and electronics (have to survive ~10 years)
- **LARGE collaborations!!!**
 - ~O(3000) physicists for ATLAS and CMS each
 - **communication, sociological aspects**
 - exponential raise of meetings, phone + video conferences...

ATLAS Collaboration

**38 countries, 177 institutes,
3000 researchers (incl. 1000 PhD students)**

July 2010

LARGE Detectors

- Everything is LARGE at the LHC...

200 MRad

Radiation Doses at LHC

- $\sim 2 \times 10^6$ Gray / r_T^2 / year at LHC design luminosity
 - where r_T [cm] = transverse distance to the beam
- Lots of R&D over >10 years to develop rad.-hard silicon detectors, gaseous detectors and electronics

**ATLAS
neutron fluences:**

**> 10^{15} n/cm²/yr
close to beam line**

Challenging Conditions: Pile-up

2012 event with pile-up: 25 reconstructed primary vertices

~7 cm

Tracking Detectors

How to measure momentum and charge?

Tracker Technologies

→ 3 major technologies of tracking detectors

● Gaseous detectors

→ **ionization in gas**

- typically ~ 100 e⁻/cm → not sufficient to create significant signal height above noise for standard amplifiers

→ typical amplifier noise = some 100...1000 ENC (equivalent noise charge, in electrons)

→ requires gas amplification $\sim 10^4$ to get enough signal over noise (S/N)

● Silicon detectors (solid state detectors)

→ **creation of electron – hole pairs in solid state material**

- typically ~ 100 e⁻ - hole pairs/ μm = 10^4 more than in gaseous detectors

→ 300 μm thick detector creates high enough signal w/o gas amplification

- $\sim 30'000$ charge carriers per detector layer, noise ~ 1000 ENC, S/N $\sim 30:1$

● rarely used: fiber trackers

→ **scintillating fibers**

- scintillation light detected with photon detectors (sensitive to single electrons)

Tracking Detector Principles

- **Typical: several layers of sensitive detector elements**
 - each layer gives a 2D hit coordinate (+ detector position → 3D)
- **Magnetic field bends (charged) particle trajectories**

can reconstruct + fit track (radius) with at least 3 hits

→ resolution of each hit depends on size d of detector elements

→ some uncertainty where the particle passed the detector element d
→ probability distribution is "flat"

→ take the width of an equivalent Gaussian distribution as resolution

e.g. for $d = 30 \mu\text{m}$ → $\sim 10 \mu\text{m}$ resolution

Magnet Concepts at LHC experiments

- + large homogenous field inside coil
- needs iron return yoke (magnetic shortcut)
- limited size (cost)
- coil thickness (radiation lengths)

(air-core) toroid

- + can cover large volume
- + air core, no iron, less material
- needs extra small solenoid for general tracking
- non-uniform field
- complex structure

Momentum Measurement

- (Only) charged particles are deflected by magnetic fields

→ homogeneous B-field → particle follows a circle with radius r

$$p_t [GeV/c] = 0.3 \cdot B [T] \cdot r [m]$$

measurement of p_t by measuring the radius

- this is just the momentum component perpendicular to the B-field = **transverse momentum p_t**
- no particle deflection parallel to magnetic field
- if particle has **longitudinal momentum** component → particle follows a **helix**

total momentum p to be measured by dip angle λ

$$p = \frac{p_t}{\sin \lambda}$$

Basic Gaseous Detector – Geiger-Müller Tube

● Geiger-Müller tube by Hans Geiger and Walther Müller 1928

- tube filled with inert gas (He, Ne, Ar) + organic vapour (e.g. CH₄) or CO₂
- central thin wire (20 – 50 μm Ø), high voltage (several 100...1000 Volts) between wire and tube

- strong increase of E-field close to the wire
 - electron gains more and more energy
- above some threshold (>10 kV/cm)
 - electron energy high enough to ionize other gas molecules
 - newly created electrons also start ionizing
- **avalanche effect**: exponential increase of electrons (and ions)
 - measurable signal on wire
 - organic substances or CO₂ responsible for “quenching” (stopping) the discharge
- absorption of UV photons

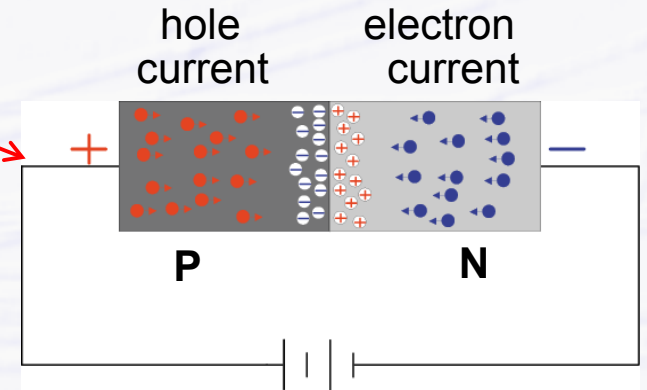

Solid State Detectors

● Basic element of a solid state (silicon) detector is... a diode

→ p-type and n-type doped silicon material is put together

Current flow through diode if connected like this

→ for use as particle detector diode needs to be connected in opposite way

charged particle can create new electron/hole pairs in depletion area sufficient to create a signal

● around junction of p- and n-type material depletion region is created

→ zone free of charge carriers

- no holes, no electrons
- thickness of depletion region depends on voltage, doping concentration

typically 20'000 – 30'000 electron/hole pairs in 300 μm thick material

Silicon Strip Detectors

- Now take a large Si crystal, e.g. 10 x 10 cm², 300 μm thick

make bottom layer p-type

and subdivide the top n-type layer into
many strips with small spacing

many diodes next to each other
with **position information**
(strip number)

- Advantage compared to wire/gas detectors**

→ strip density (pitch) can be rather high (e.g. ~20 μm)

- high single point accuracy: $\sigma_x = 20 \mu\text{m} / \sqrt{12} = 5.8 \mu\text{m}$
- but also many electronics channels

Si-Detector Electronics and Si-Pixels

- Silicon strip detectors have a laaaarge number of electronics channels, $\sim 10^7$ each for ATLAS and CMS Si trackers
 - requires highly integrated chips for amplification, shaping, zero suppression (only information of strips with signals is read-out) and multiplexing (put all strip signals on a few cables only)
- ➔ electronics is directly connected to the sensor (the “multi-diode”) via wire bonds

wire bonds

Sensor

Si-strip detectors provide only 1 coordinate, Pixel detectors are 2D detectors

Pixel detector need “bump” bonding and have even more channels, $\sim 10^8 - 10^9$

ATLAS Inner Tracker

- 4-layer Si Pixel
 - 3 → 4 layers in 2014
- 4-layer Silicon Strips
- Transition Radiation Tracker (gaseous)

Pixel alignment with cosmic rays 2008

The ATLAS Pixel Detector

- Re-insertion in December 2013 during Long Shutdown 1

CMS Full Silicon Tracker

Tracker Inner Barrel TIB

- **4-layers Si Pixel**
 - 3 → 4 layers in 2017
- **10-layers Silicon Strips**
 - 210 m², largest silicon detector ever built

Material Budget

- Tracking Detectors should be light-weighted and thin
 - multiple scattering by material degrades resolution at low momenta
 - unwanted photon conversions in front of calorimeters
 - material often very inhomogeneous (in particular Si detectors)
- Power & cooling adds most of the material

not the Si sensor material

ATLAS

$ \eta $	radiation length	interaction length
< 1	$\sim 0.2 X_0$	$\sim 0.05 \lambda$
< 3.3	$\lesssim 0.5 X_0$	$\lesssim 0.2 \lambda$

CMS

Calorimeters

How to measure energy?

Particle Showers in Calorimeters

- Initial particle creates electro-magnetic shower of secondary particles (electrons, positrons, photons) in dense material

→ by bremsstrahlung and pair production

→ shower depth depends on **radiation length X_0** (characteristic material constant)

→ for e^\pm = length after all but 1/e of energy lost by Bremsstrahlung

→ for γ = 7/9 of mean free path length for pair production

shower maximum

80 GeV electron in lead glass block

energy profile

Energy Resolution of Calorimeters

- Number of particles in shower is proportional to energy of initial particle

$$N_{shower} \propto \frac{E}{E_c} \quad \leftarrow \text{Critical Energy (typically } \sim 10 \text{ MeV)}$$

- error of energy measurement determined by (statistical) fluctuations in the number of shower particles

$$\sigma_{N_{shower}} \propto \sqrt{N_{shower}}$$

- resulting relative energy measurement error is

$$\frac{\sigma_E}{E} \propto \frac{1}{\sqrt{E}}$$

- More contributions from detector inhomogeneities and electronic noise

Calorimeter Concepts

● Homogeneous calorimeters (e.g. CMS)

→ absorber material (generation of the shower) = detector material

- typically an electromagnetic shower is created in an optical transparent absorber, photons created in the shower are collected and detected with some photo detector

● Sampling calorimeters (e.g. ATLAS)

→ passive (heavy) absorber material (iron, copper, lead, tungsten, uranium) interleaved with active detector material

CMS: Homogeneous EM Calorimeter

- **Clear advantage: good energy resolution**

- the entire shower is kept in active detector material

- no shower particle is lost in passive absorber

- **Disadvantages**

- limited granularity, no information on shower shape in longitudinal direction (along particle flight direction)

- position information is useful to resolve near-by energy clusters, e.g. single photons versus two photons from π^0 decay

CMS PbWO₄ crystal

dense, transparent materials needed with short radiation length and high light yield

ATLAS: Sampling EM Calorimeter

- Typical sampling calorimeters use iron or lead absorber material, variety of detectors in between possible
 - gas detectors (MWPCs), plastic scintillators, **liquid noble gases** (LAr, LKr)
- LAr with “acordeon” shaped Fe-Pb-Fe absorbers at ATLAS
 - LAr is ionized by charged shower particles
 - Charge collected on pads
 - ionization chamber, no “gas” amplification
 - pads can be formed as needed → high granularity
 - acordeon structure helps to avoid dead zones (cables etc.)

simulated shower

ATLAS LAr calorimeter

ATLAS/CMS Hadron Calorimeters

- Measure energy of heavy hadronic particles: π , K , p , n , ...
- Energy resolution much worse than for el.-magn. calorimeters
 - shower created by nuclear interactions (hadronic shower, fewer particles in shower)
 - usually only a few nuclear interaction lengths deep ($5 - 6 \lambda_I$)
- Both ATLAS and CMS use scintillators as detector material
 - need many optical fibers to transport light from scintillators to photo detectors

ATLAS

CMS

ATLAS Muon Detector

- Muon detectors are **tracking detectors** (e.g. wire chambers)

- they form the outer shell of the (LHC) detectors
- they are **not only sensitive to muons** (but to all charged particles)!
- just by “definition”: if a particle has reached the muon detector
→ it's considered to be a muon
- all other particles should have been absorbed in the calorimeters

- **Challenge for muon detectors**

- large surface to cover (outer shell)
- keep mechanical positioning stable over time

Aluminum tubes with central wire filled with 3 bar gas

- **ATLAS Muon System**

- 1200 chambers with 5500 m²
- needs also good knowledge of (inhomogeneous) magnetic field

ATLAS Muon Detector Elements

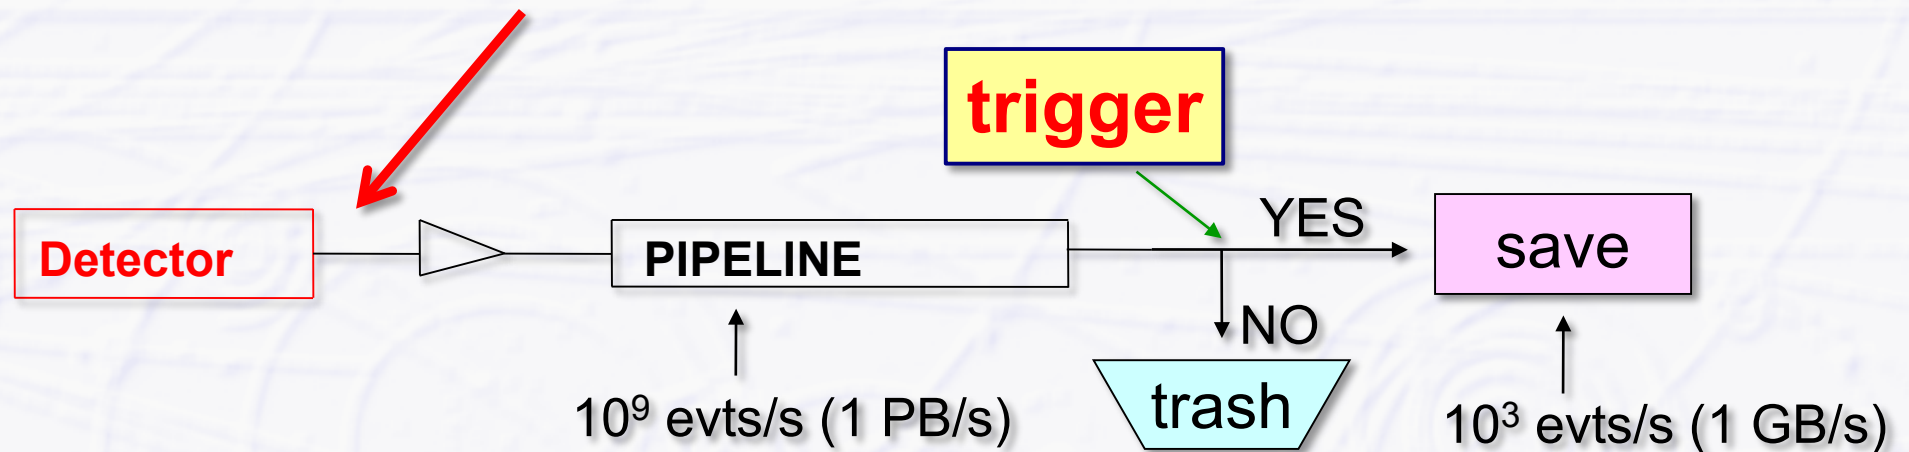

ATLAS Detector Status

(a 100 megapixel camera with 40 MHz framerate = 1 PB/second)

Subdetector	Number of Channels	Approximate Operational Fraction

CSC Cathode Strip Chambers	31 k	98.4%
RPC Barrel Muon Chambers	370 k	96.6%
TGC Endcap Muon Chambers	320 k	99.6%

How to Select Interesting Events?

- **Bunch crossing rate: 40 MHz, ~20 interactions per BX (10^9 evts/s)**
 - can only record ~1000 event/s (1 MB each), still ~1 GB/s data rate
- **Need highly efficient and highly selective TRIGGER**
 - raw event data (**1 PB/s**) are stored in pipeline until trigger decision

- **ATLAS + CMS triggers have 2 levels**
 - **Level-1: hardware (FPGAs), ~3 μ s decision time, 40 MHz \rightarrow 100 kHz**
 - **Level-2: software (computer farm), ~4 s decision time, 100 kHz \rightarrow 1 kHz**

Reconstruction

Analysis

Simulation (Monte-Carlo)

● **We need to go from raw data back to physics**

→ reconstruction + analysis of the event(s)

Simulation (Monte Carlo)

- **Even with best calibration + alignment**

- some detector influence, e.g. efficiency for track reconstruction etc. will not be known well enough from data
- Use detector simulation (Monte Carlo) to “unfold” detector influence

- **Event “generator” simulates physics processes**

- **Full detector description**

- geometry, detector volumes, detector response (noise etc.)
- physics interactions with matter and tracking particles through detector volumes
- also needed for detector design studies before detector actually built

ATLAS (A Toroidal LHC ApparatuS)

CMS (Compact Muon Spectrometer)

main assembly on surface,
then lowering into cavern in
5 big parts by ~2500 t crane

ATLAS/CMS Concept Overview

- The two large LHC detectors have somewhat different concepts

→ ATLAS

- small inner tracker with moderate field (small 2 T solenoid)
- electron identification by transition radiation tracker
- sampling calorimeter with high granularity outside solenoid
- air-core toroid system for good muon momentum measurement

emphasis on granular calorimeter and good muon measurement

→ CMS

- large inner tracker with high B-field (large 4 T solenoid)
- no dedicated particle identification detector
- homogeneous crystal calorimeter with good energy resolution inside solenoid

emphasis on good general tracking and good energy resolution

- However, both detector concepts have very similar performance for Higgs physics (efficiency, mass resolution...)
