The milliQan experiment: search for milli-charged particles at the LHC

- Haitham Zaraket (milliQan)
  haitham.zaraket@cern.ch
- Lebanese University (LU)
- Multidisciplinary Physics Lab.
SM and BSM, Dark sector, …

Charge: $\pm \frac{2e}{3}, \pm \frac{e}{3}, \pm e$

Symmetries: Sequential SM

Portal? Gauge, Millicharged particles, …

Detection? Background? Sensitivity?

Charge? Fractions of e

Symmetries? $U'(1)$, $\zeta$

Mass? Stability? $\gamma'$, $Z'$

$W', Z'$
Different models

Millicharged particles (mCPs) as Candidates for Dark Matter

- Holdom Phase: Massless B’
- Okun Phase: Massive B’
- Mixed Phase: Combination of massless and Massive fields as it is the case in SM for B (combination of photon and Z). Hence leading to Z’ and dark photon.
Simple model of millicharged particles

• Extra abelian gauge field that couples to a massive Dirac fermion (“dark QED”) and that mixes with hypercharge through the kinetic term:

\[
L = L_{SM} - \frac{1}{4} A'_{\mu \nu} A'^{\mu \nu} + i \overline{\Psi} (\partial_\mu \gamma^\mu + ie' A'_\mu \gamma^\mu + iM_{mcp}) \Psi - \frac{\kappa}{2} A'_{\mu \nu} B^{\mu \nu}
\]

\( \kappa \ll 1 \) and as usual in SM \( B_\mu = \cos \theta_w A_\mu - \sin \theta_w Z_\mu \)

Redefinition of the new gauge boson:

\[ A'_\mu \rightarrow A'_\mu - \kappa B_\mu \] will get rid of gauge fields mixing/interaction

\[
L = L_{SM} - \frac{1}{4} A'_{\mu \nu} A'^{\mu \nu} + i \overline{\Psi} (\partial_\mu \gamma^\mu + ie' A'_\mu \gamma^\mu + iM_{mcp} - ike' \cos \theta_w A_\mu \gamma^\mu - i\kappa \sin \theta_w Z_\mu \gamma^\mu) \Psi
\]
Mixed Model for millicharged Particle

In addition to SM particles: massless dark photon \((A')\) and a massive dark \(Z\) boson \((Z')\)

\[
L = L_{SM} + L_{DM} - \frac{\kappa}{2} B_{\mu \nu} B^{\mu \nu} \quad \text{with again } \kappa \ll 1 \quad \text{and } B'_\mu = \cos \theta'_w A'_\mu - \sin \theta'_w Z'_\mu
\]

More parameters,
New couplings between the Dark sector fermions and SM particles.
Keeping only terms to the first order of \(\kappa\)

\[
L \sim e' A'_J_{EM} \oplus A. (e J_{EM} - \kappa_{cc} e' J'_J_{EM}) \oplus Z. \left[ \frac{g_2}{\cos \theta_w} J_Z + e' \kappa_{sc} J'_{EM} - \frac{g'_2}{\cos \theta'_w} \kappa_{ss} \frac{M_Z^2}{M_Z^2 - M_{Z'}^2} \right]
\]

More models, Massive \(A'\), ……..

Choose the model first simple model, less free parameters
Production mechanisms (proton-proton, LHC):

QCD inspired, just multiplying by $Q^2$

$\zeta^+, \eta, \eta', \pi^o \rightarrow \zeta^- \zeta^+ \gamma; \rho \rightarrow \zeta^- \zeta^+; \phi, \frac{f}{\psi}, \ldots \rightarrow \zeta^- \zeta^+$;

Important below few GeV

Plus Drell-Yan, Modified MADGraph
Detection? Small charge? Not too heavy?

mCP can decay but can travel to detector and scatter on detector particles

\[
\frac{dE}{dx} \sim Q^2
\]

Energy loss: \(\frac{dE}{dx} \sim Q^2\) ..... Charge \(Q \sim 10^{-3}e \rightarrow 10^6\) higher sensitivity is needed compared to \(e\)-charged particles, need for abundant source \(\rightarrow\) LHC, screened from background, Rock barrier, still cosmic particles as background
design requirements

- Long active material,
- Several aligned scintillators, three, then four
- Well isolated from main background, calibration & Triple coincidence (15 ns)
- High sensitivity, single photo-electron
- Not affecting existing LHC experiments
- Low cost
- Modular design as an option, future extension is possible
- Detection concept:

- 1m x 1m x 3m structure
- 3 layers 80cm x 5cm x 5cm Scintillators
- Particles produced from IP will traverse the three layers
- Coincidence is a key factor
- Straight line trajectories, with B-effect
- Time of flight (TOF)
Located in tunnel above CMS experiment (33 m, $\phi \sim 43^{\circ}$, $\eta \sim 0.7$)
Milliqan milestones: Paper, LOI, then a 1% version, looking for full detector

- Installed Fall 2017
- 3 layers of 2x3 scintillator+PMT
- Scintillator slabs and lead bricks Tag thru-going particles
- Scintillator panels to cover top and side, cosmic muons reject
- Hodoscope, Get tracks of beam
• In situ charge calibration
• Alignment with CMS IP
• Understanding tracking, coincidence, triggering, timing using muons from collision
• Byproduct, realistic sensitivity curves for full Milliqan detector.
• Byproduct, continuous monitoring of CMS beam as a check.
Low mass (0.1-1 GeV) sensitivity to mCP with $Q \sim 10^{-3} e$
Current agenda:
• Analyzing collected data
• Full simulation updated
• Grant awaiting for full construction.
Upgrading, mechanical

- Easy to upgrade
- Possibility to replace any defected module
Conclusions and results

- Millicharge particle as an interesting candidate could be spotted with existing particle physics colliders, CMS, explored parameters: low mass (0.1-few GeV) sensitivity to mCP with $Q \sim 10^{-3} e$.

- A demonstrator is already installed, fall 2017, data was taken, now analyzed, calibration was also made.

- In situ calibration was possible.
- Triggering-rechecked and background understanding ongoing.
- Full detector mechanical structure design done.
- Full GEANT simulation of detector.

- We are ready to go, however …

- Unfortunately haven’t successfully secured funding – despite (well reviewed) proposals to various agencies & foundations different sources.

- Without funding soon, the opportunity to carry out this interesting (and relatively cheap) extension of the LHC physics program will be put in jeopardy.
