Anomalous production at various collider options

The discovery capacity of LHC and lepton collider could be enlarged if the anomalous interactions of the fourth generation fermions with the first three ones exist. Such anomalous interactions seems to be quite natural due to large masses of the fourth generation fermions.

Anomalous single productions of the fourth generation quarks at the LHC

PHYSICAL REVIEW D 78, 075018 (2008)

Anomalous single production of the fourth generation quarks at the CERN LHC

R. Çiftçi*

Department of Engineering of Physics, Faculty of Engineering, Ankara University, 06100 Tandoğan, Ankara, Turkey
(Received 27 July 2008; published 21 October 2008)

Possible anomalous single productions of the fourth standard model generation up and down type quarks at CERN Large Hadron Collider are studied. Namely, $pp \rightarrow u_4(d_4)X$ with subsequent $u_4 \rightarrow bW^+$ process followed by the leptonic decay of the W boson and $d_4 \rightarrow b\gamma$ (and its H.c.) decay channel are considered. Signatures of these processes and corresponding standard model backgrounds are discussed in detail. Discovery limits for the quark mass and achievable values of the anomalous coupling strength are determined.

Sultansoy, TOBB ETU, Turkey; A.K. Ciftci, Ankara U., Turkey; H. Aksakal, Nigde U., Turkey

Abstract

We describe various parameter scenarios for a linac-ring ep collider based on LHC and an independent electron linac. Luminosities between 10^{31} and $10^{33} \text{ cm}^{-2} \text{ s}^{-1}$ can be achieved with a s.c. linac, operated either pulsed or in cw mode with optional recirculation, at a total electric wall-plug power of order 20 MW. Higher luminosities of several $10^{33} \text{ cm}^{-2} \text{ s}^{-1}$ can be reached by investing more electric power or by energy recovery. Finally, merits of a linac-ring ep collider are discussed.

SCENARIOS

Colliding the LHC 7-TeV protons with a 25–140 GeV e^\pm beam would both extend the discovery reach of the LHC, and enable precision physics with LHC data [1, 2], e^+p collisions are desirable in addition to e^-p . One way to realize such ep collider is by installing a new lepton ring in the LHC tunnel, involving a new lepton injector too [3, 4]. The THERM study [5] inspired looks at an alternative LHC-based “QCD Explorer” colliding LHC protons with electrons delivered by a linac [6].

Possible linac-ring scenarios include a n.c. linac, a pulsed s.c. linac, and a cw s.c. linac with or without energy recovery in various configurations, as shown in Fig. 1.

Figure 1: Scenarios for the linac-ring ep collider.

A s.c. linac can accelerate long trains of bunches with 25 or 50 ns spacing, matching the LHC fill pattern. Therefore, its luminosity in collisions with the LHC can be much

Table 1: Proton beam scenarios

	$N_{p,p}$	T_{pp}	$e_p \gamma_p$	β_p^*
LHC	1.7×10^{11}	25 ns	$3.75 \mu\text{m}$	0.25 m
LHC*	5×10^{11}	50 ns	$3.75 \mu\text{m}$	0.10 m

ter is decelerated [8]. More conventional energy recovery is possible by means of a recirculating linac, e.g. similar to ELFE [9], or with a tumaround loop as proposed for a future X-ray FEL [10]. Possible layouts are sketched in Fig. 2. For highest beam energy, the ERL with its recircu-

Figure 2: Example linac layouts on LHC site.

lating arcs could be installed in the LHC tunnel itself, blurring the distinction between ring-ring and linac-ring LHeC options [11].

Two proton scenarios are listed in Table 1: (1) the nominal LHC beam combined with reduced proton interaction-point (IP) beta functions β_p^* of 0.25 m as foreseen for 2013, and (2) a higher brightness beam [corresponding to scenario “LPA” of [12]] available from an upgraded LHC injector chain, including a 5 GeV s.c. proton linac (SPL) and a 50-GeV synchrotron (PS2), by 2017. This second scenario also assumes $\beta_p^* = 0.1 \text{ m}$, which may be possible by (1) focusing only one of the two proton beams, thereby relaxing aperture constraints; (2) dedicated ep runs, allowing for a chromatic correction twice as strong as for two low- β

Abstract

Gamma-proton collisions allow unprecedented investigations of the low x and high Q^2 regions in quantum chromodynamics. In this paper, we investigate the luminosity for "ILC" \times LHC ($\sqrt{s_{ep}} = 1.3$ TeV) and "CLIC" \times LHC ($\sqrt{s_{ep}} = 1.45$ TeV) based γp colliders. Also we determine the laser properties required for high conversion efficiency.

(a) $q_4 \rightarrow \gamma q$ anomalous process and (b) $q_4 \rightarrow Zq$ anomalous process

The Fourth SM Family Leptons and Quarks

A.Kenan Çiftçi

Introduction

- Fourth Generation
- Anomalous production LHeC
- γp Collider

Anomalous Interactions

- Lagrangians
- Width and BR

Selected Processes

- $ep \rightarrow l_4 \rightarrow Ze$
- $ep \rightarrow \nu_4 \rightarrow W\ell$
- $(ep, \gamma p) \rightarrow q_4 \rightarrow ?$

Conclusion

Conclusion

When the anomalous coupling for strong interactions is close to one, ep and γp colliders are almost blind to anomalous interactions of the fourth generation quarks.

In this case, hadron colliders like LHC will be discovery machines.

ep and γp colliders enable us to investigate effects of both anomalous couplings of electromagnetic and weak interactions for $\kappa_g^{qi} = 0$.

- This type anomalous interactions takes place through Weizsacker-Williams photons or Z boson at the LHC.
- However, LHC based ep and γp colliders have better observation reaches of anomalous couplings compare to the LHC.

The advantage of the γp collider with respect to ep collider for single production of q_4 is obvious even with 1/100 (for $q_4 \rightarrow \gamma q$) and 1/10 (for $q_4 \rightarrow Zq$) of luminosity of ep collider.

ep and γp colliders are almost only place to investigate anomalous coupling strengths of electroweak interactions separately.

Such as κ_Z^{qq4} , κ_γ^{qq4} , κ_Z^{ll4} , κ_γ^{ll4} and $\kappa_W^{l\nu4}$
