

# **Sensitivity of integrated luminosity for beam parameter change**

F. Antoniou, R. De Maria, S. Fartoukh, N. Karastathis,  
Y. Papaphilippou, D. Pellegrini, K. Sjobaek

WP2 meeting, 17/01/2017

# Outline

- Xing angle choice during levelling
- Impact on levelling ( $\beta^*$  vs. separation)
- Experience 2016:
  - Luminosity lifetime, blow-up, impact on estimated performance
  - Levelling tests
  - Availability
- Projection on integrated luminosity performance

# Global DA scanning of parameters

- Tracking set-up:
  - HL-LHC optics v1.2, half available crab voltage
- Octupoles set to 0, chromaticity of 3, nominal tunes
- IP1, IP5 and IP8 head-on, IP2 separated (halo collisions)
- Assuming constant (round) emittance of  $2.5\mu\text{m}$
- Tracking with SixTrack for  $10^6$  turns and estimating DA (minimum over 5 angles)
- Scanning of crossing angle vs.  $\beta^*$  and vs. separation, for various intensities
- Superimposing luminosity curves for the various parameters

# Global DA scanning of parameters

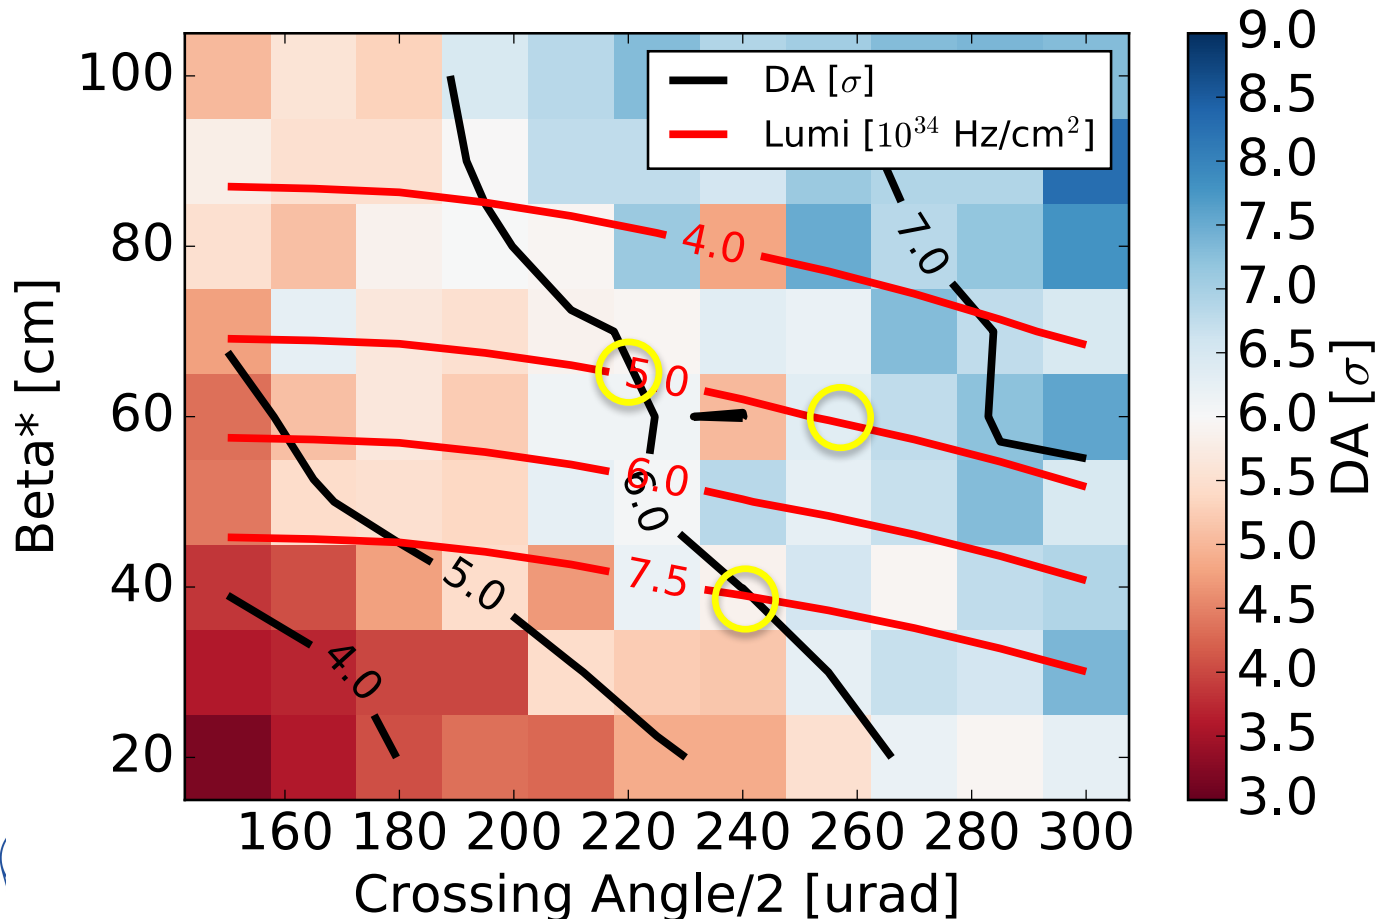

- Tracking set-up:
  - HL-LHC optics v1.2, half available crab voltage
- Octupoles set to 0, chromaticity of 3, nominal tunes
- IP1, IP5 and IP8 head-on, IP2 separated (halo collisions)
- Assuming constant (round) emittance of  $2.5 \mu\text{m}$  along stable beams
- Tracking with SixTrack for  $10^6$  turns and estimating DA (minimum over 5 angles)
- Scanning of crossing angle vs.  $\beta^*$  and vs. separation, for various intensities
- Superimposing luminosity curves for the various parameters
- Target DA of  $6 \sigma$ , as simulation scenario is optimistic (no errors, no octupoles, low chromaticity,...)

# Start of levelling $N_b = 2.2 \times 10^{11}$

- Full crossing angle could be reduced to 440  $\mu\text{rad}$  ( $\sim 19.4 \sigma$  separation @ 65 cm  $\beta^*$ ), keeping the 6  $\sigma$  DA and the luminosity at  $5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$
- Even for min.  $\beta^*$  of 20 cm @ 510  $\mu\text{rad}$ , DA  $\sim 5.5 \sigma$
- For  $7.5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ , the leveling could start at 40 cm with a crossing angle of 480  $\mu\text{rad}$  (16.6  $\sigma$ )

S.Fartoukh, N. Karastathis, D. Pellegrini

Min DA;  $I = 2.2\text{e}11$ ;  $I_{\text{MO}} = 0 \text{ A}$ ;  $Q' = 3 \#$

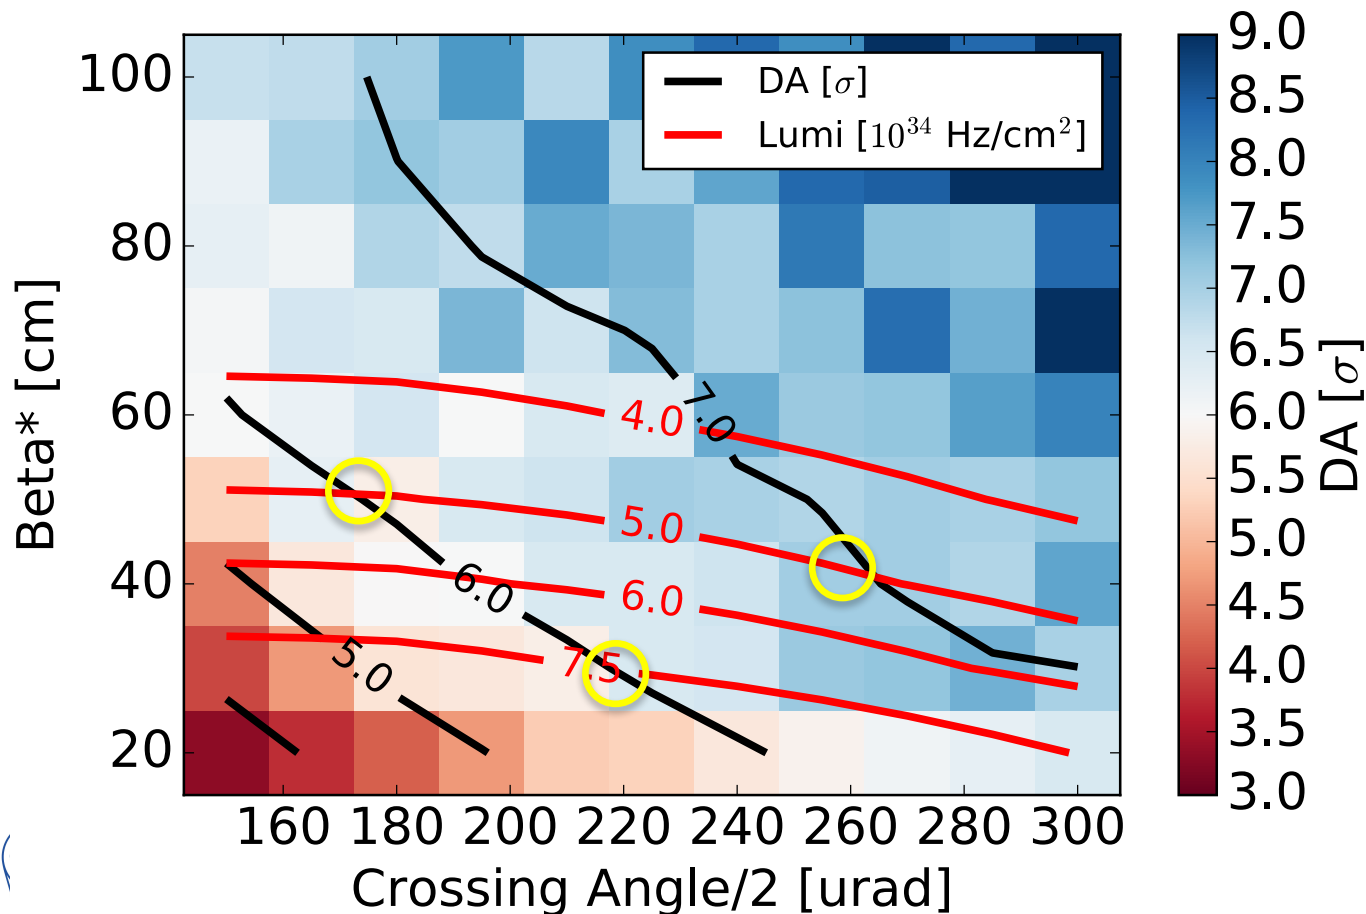

# During levelling, $N_b = 1.9 \times 10^{11}$

- Full crossing angle could be reduced to  $340 \mu\text{rad}$  ( $\sim 13.1 \sigma$  separation @  $50 \text{ cm } \beta^*$ ), keeping the  $6 \sigma$  DA and the luminosity at  $5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$
- For  $7.5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ , a DA of  $6 \sigma$  is obtained with a crossing angle of  $440 \mu\text{rad}$  ( $13.2 \sigma$  @  $30 \text{ cm}$ )

S.Fartoukh, N. Karastathis, D. Pellegrini

Min DA;  $I = 1.9\text{e}11$ ;  $I_{MO} = 0 \text{ A}$ ;  $Q' = 3 \#$

# During levelling, $N_b = 1.6 \times 10^{11}$

- Full crossing angle could remain at  $340 \mu\text{rad}$  ( $\sim 11 \sigma$  separation @  $35 \text{ cm } \beta^*$ ), keeping the  $6 \sigma$  DA and the luminosity at  $5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$
- For  $7.5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ , a DA of  $6 \sigma$  is obtained with a crossing angle of  $430 \mu\text{rad}$  ( $10.5 \sigma$  @  $20 \text{ cm}$ , i.e. reaching the end of  $\beta^*$  levelling)

S.Fartoukh, N. Karastathis, D. Pellegrini

Min DA;  $I = 1.6\text{e}11$ ;  $I_{M0} = 0 \text{ A}$ ;  $Q' = 3 \#$

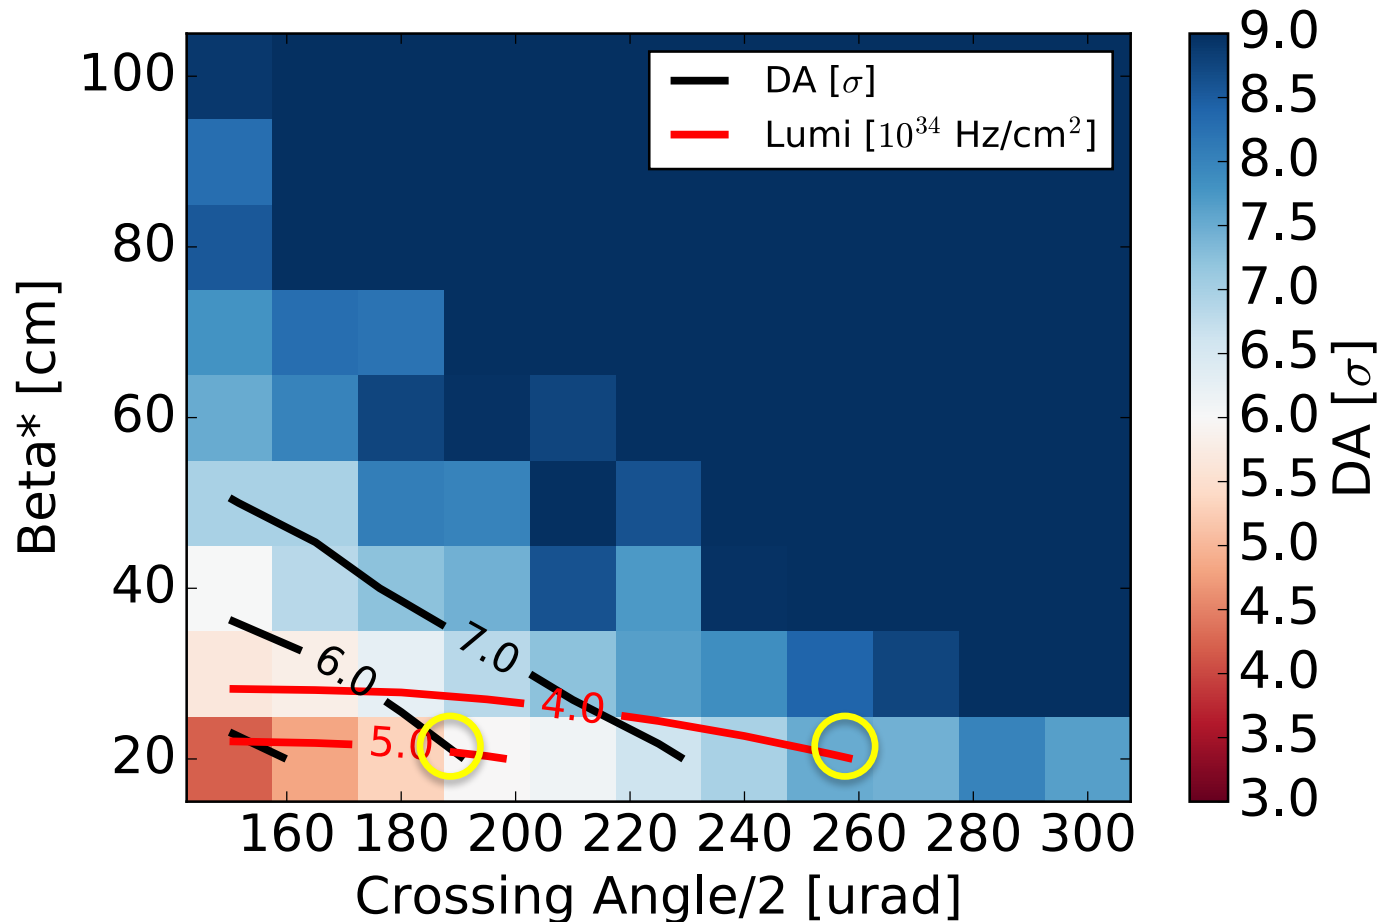

# End of levelling, $N_b = 1.275 \times 10^{11}$

- Full crossing angle should be increased to 380  $\mu\text{rad}$  ( $\sim 9.3 \sigma$  separation @ 20 cm), keeping 6  $\sigma$  DA and luminosity of  $5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$

S.Fartoukh, N. Karastathis, D. Pellegrini

Min DA;  $I = 1.275\text{e}11$ ;  $I_{MO} = 0 \text{ A}$ ;  $Q' = 3 \#$

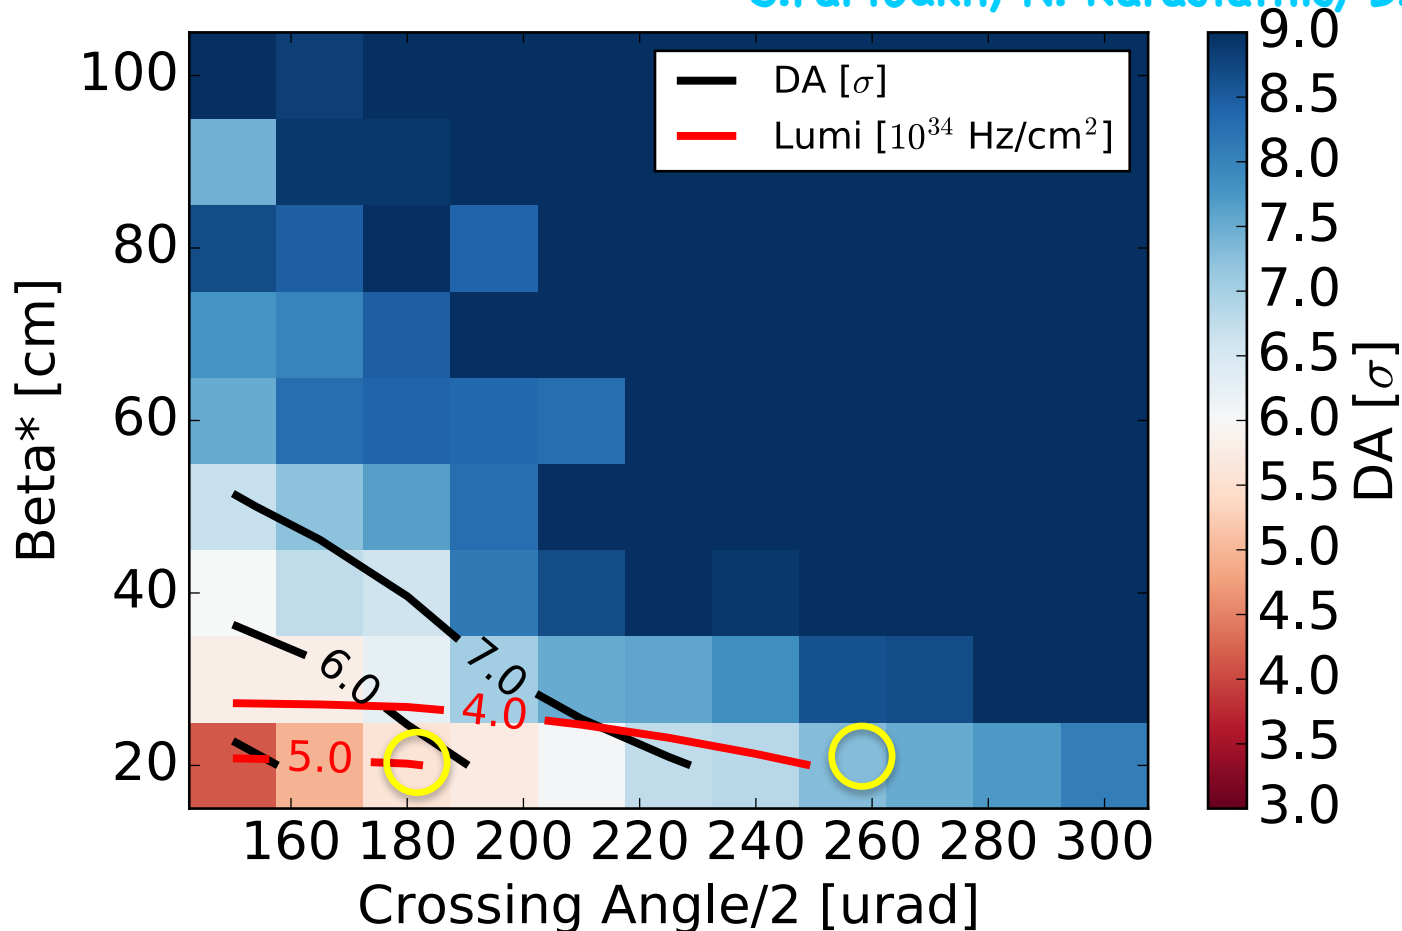

# Extra levelling, $N_b = 1.25 \times 10^{11}$

- Some extra levelling time can be gained by levelling with the crossing angle at DA close to  $6\sigma$  and constant  $\beta^*$  of 20 cm

Min DA;  $I = 1.25e11$ ;  $I_{MO} = 0$  A;  $Q' = 3 \#$

S.Fartoukh, N. Karastathis, D. Pellegrini

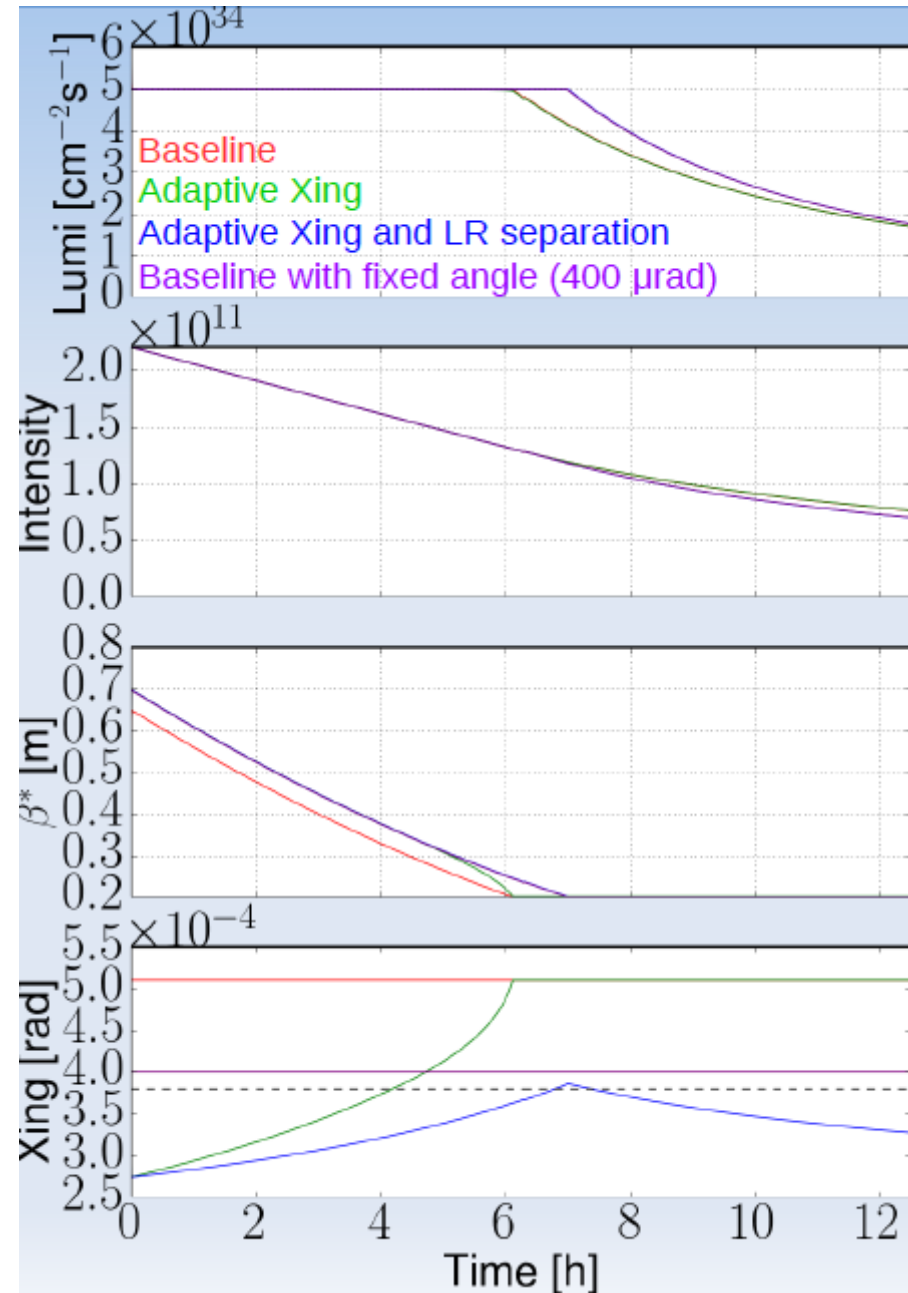

# A few remarks

- Crossing angle can be reduced during levelling to  $6 \sigma$  DA, reducing pile-up density and triplet irradiation
- Full crabbing can be achieved with two cavities (max kick of  $380 \mu\text{rad}$ ) for currents  $< 2 \times 10^{11}$  almost through the whole levelling process
- Some small leveling time (and performance) can be gained @ 20 cm, by levelling with the crossing angle
- Need to complement the DA simulations down to 15 cm especially for the ultimate scenario and span also lower crossing angles

# Performance

Estimate impact in integrated luminosity and pile-up density for nominal and ultimate, for mentioned “crossing adaptive levelling”

X. Buffat, HL-LHC meeting 2016

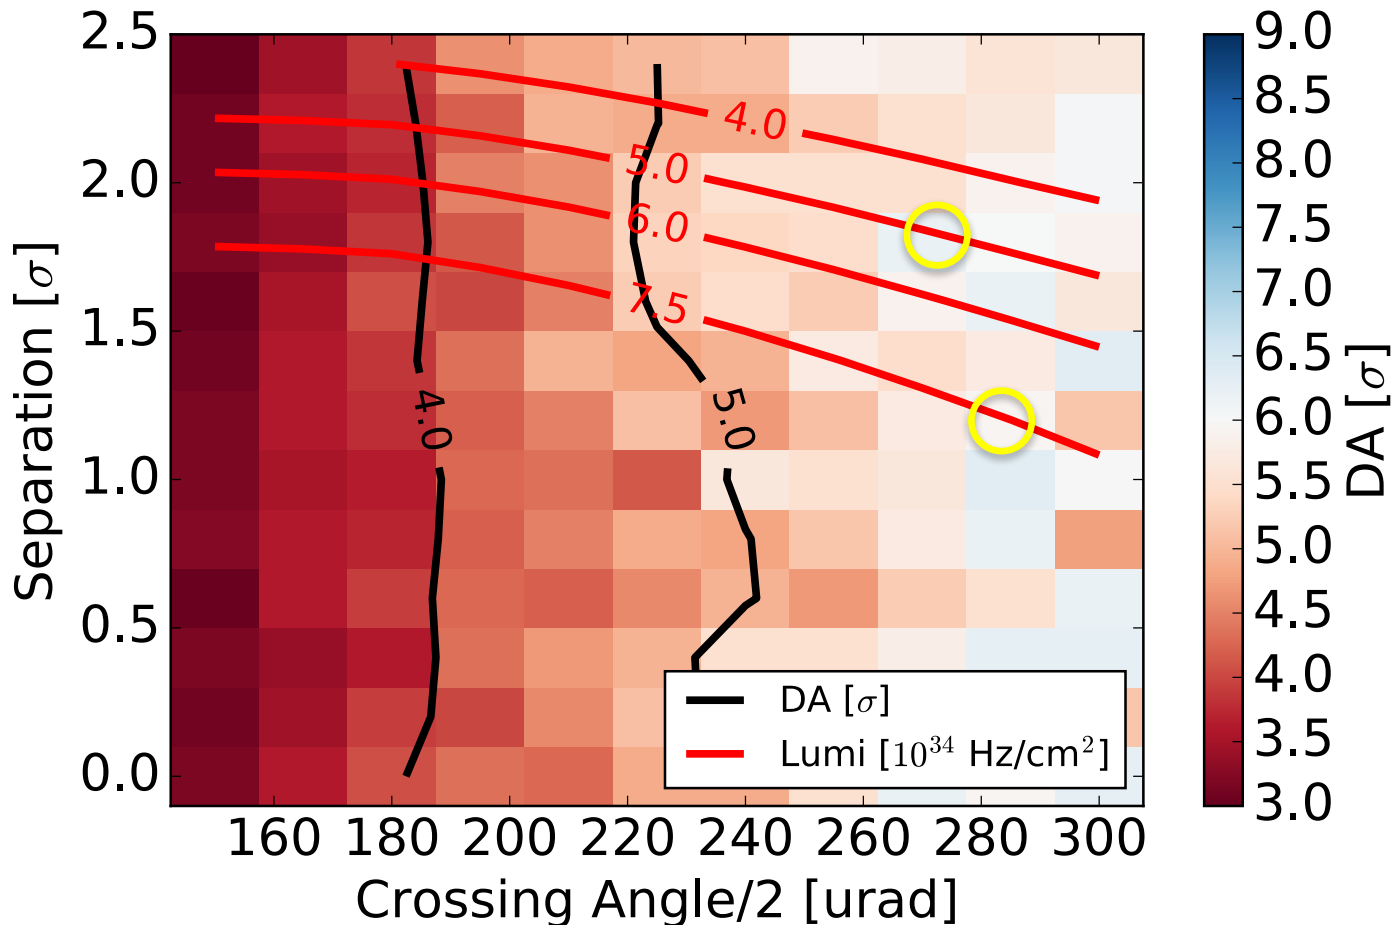

# Separation levelling $N_b = 2.2 \times 10^{11}$

- $\beta^*$  kept constant while levelling the luminosity by separation
- For  $5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ , the leveling could start at  $1.8 \sigma$  separation with a large crossing angle of  $550 \mu\text{rad}$  ( $13.4 \sigma$ )
- For  $7.5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ , the leveling could start at  $1.2 \sigma$  with a crossing angle of  $580 \mu\text{rad}$  ( $14.2 \sigma$ )

S.Fartoukh, N. Karastathis, D. Pellegrini

Min DA;  $I = 2.2\text{e}11$

# Separation levelling $N_b = 1.9 \times 10^{11}$

- DA seems quite independent on separation
- For both nominal (1.6  $\sigma$  separation) and ultimate (1  $\sigma$  separation), a crossing of 500  $\mu\text{rad}$  (12.2  $\sigma$ ) maintains DA

S.Fartoukh, N. Karastathis, D. Pellegrini

Min DA;  $I = 1.9\text{e}11$

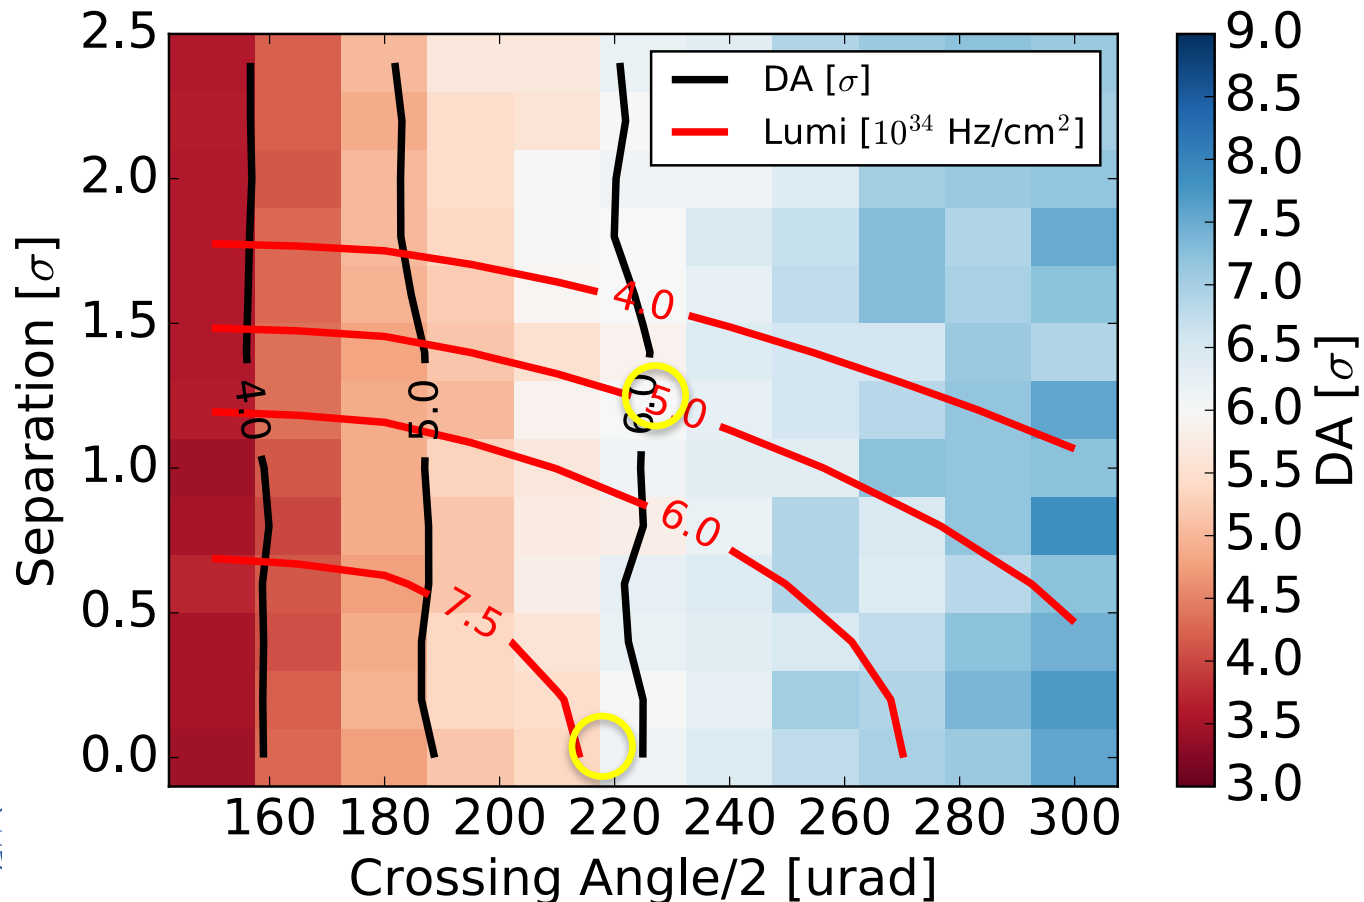

# Separation levelling $N_b = 1.6 \times 10^{11}$

- DA seems again quite independent on separation
- For  $5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ , the leveling could continue with a  $1.2 \sigma$  separation with a crossing angle of  $450 \mu\text{rad}$  ( $11 \sigma$ )
- For  $7.5 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$ , the leveling can stop @ a crossing angle of  $440 \mu\text{rad}$  ( $10.8 \sigma$ )

S.Fartoukh, N. Karastathis, D. Pellegrini

Min DA;  $I = 1.6\text{e}11$

# Separation levelling $N_b = 1.275 \times 10^{11}$

- Separation levelling for nominal scheme ends @ 380  $\mu\text{rad}$  ( $\sim 9.3 \sigma$ )

S.Fartoukh, N. Karastathis, D. Pellegrini

Min DA;  $I = 1.275e11$

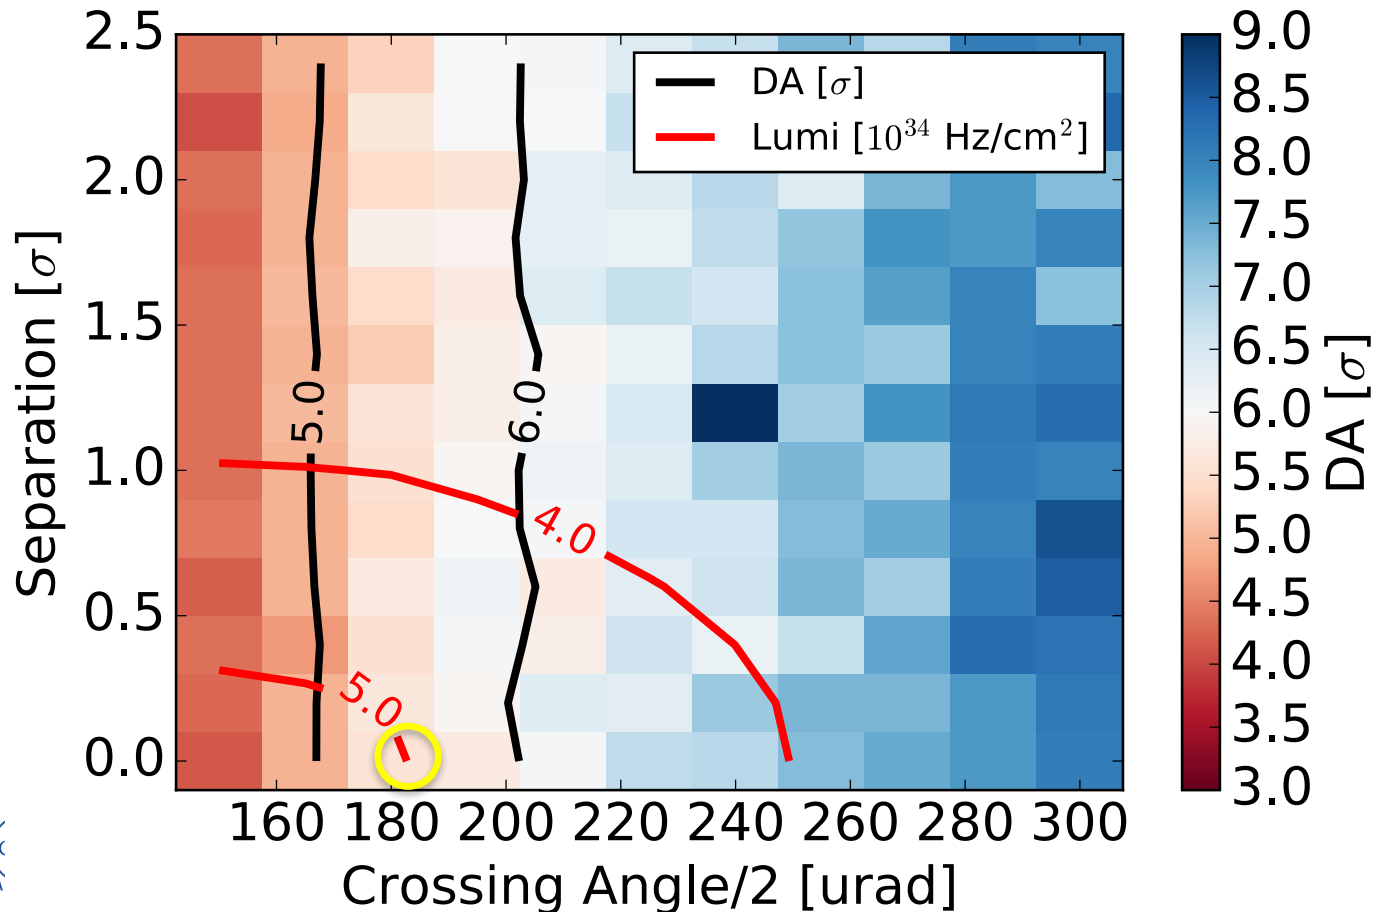

# Separation levelling $N_b = 1.2 \times 10^{11}$

- The same crossing angle levelling scheme can be pursued as before to gain some extra levelling time and optimize performance

S.Fartoukh, N. Karastathis, D. Pellegrini

Min DA;  $I = 1.25e11$

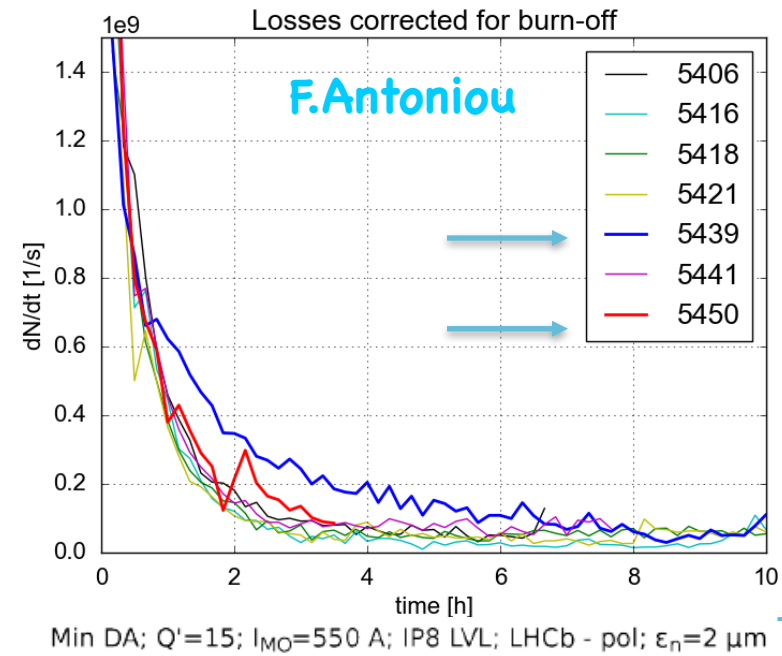

# Levelling experience in 2016

❑ **Levelling by separation** demonstrated in test fills during 2016

❑ **Fine tune** adjustments and **reduction** of **octupoles/chromaticity** necessary to improve lifetime during levelling

❑ Satisfying possible request of **experiments** or when reaching **cryogenics' limit**

❑ **Changing X-angle** from fill-to-fill (adapt **H/V emittance ratio** or **increase peak luminosity**) or **levelling** during stable beams (range of 60  $\mu\text{rad}$  in X/2-angle)

# Beam losses

F.Antoniou, Evian 2016

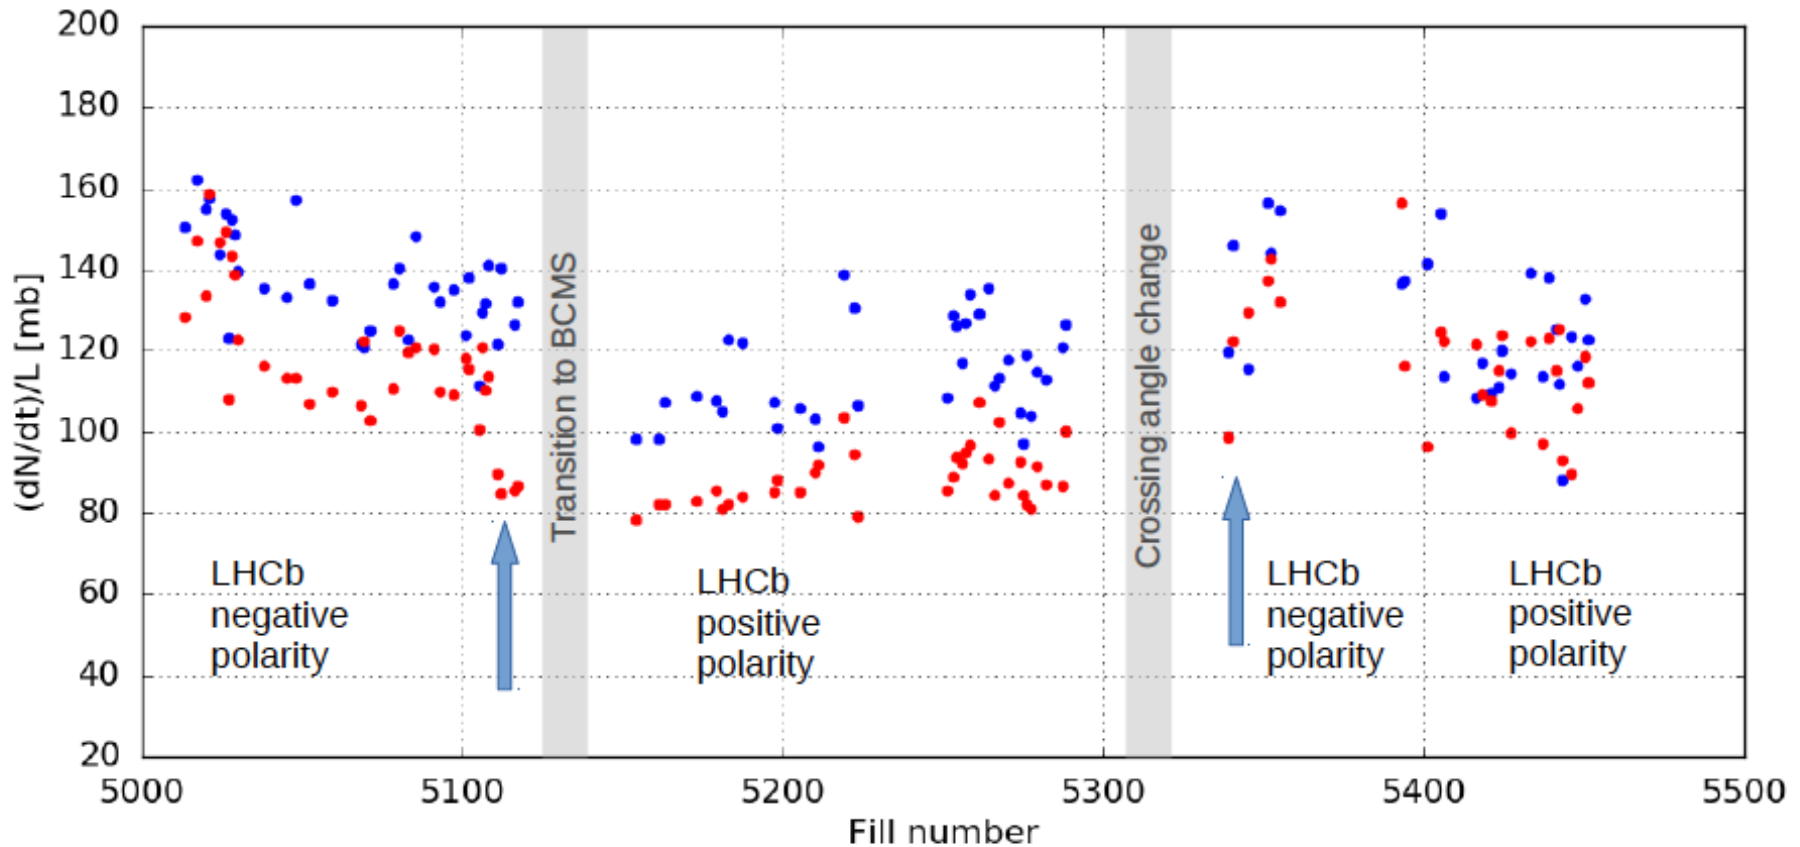

- Normalized loss rate for all fills
- Losses on-top of Burn-off were observed for many fills
- Mainly the first 3h and then become burn off dominated

# Beam losses

Averaged over the first 1.0h

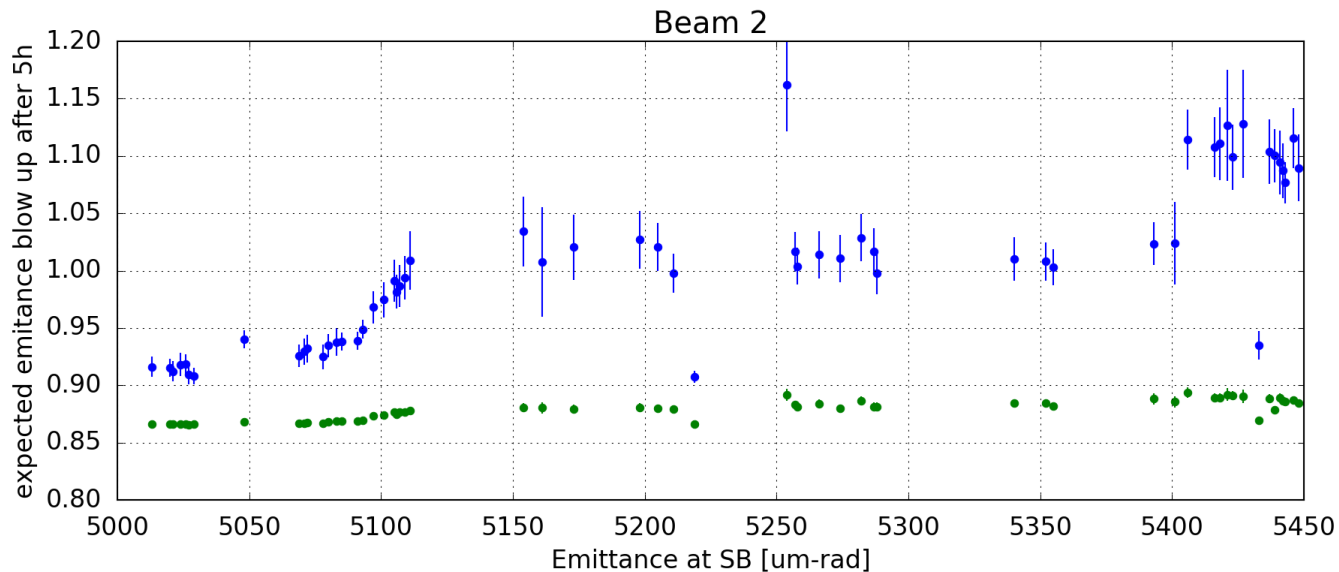

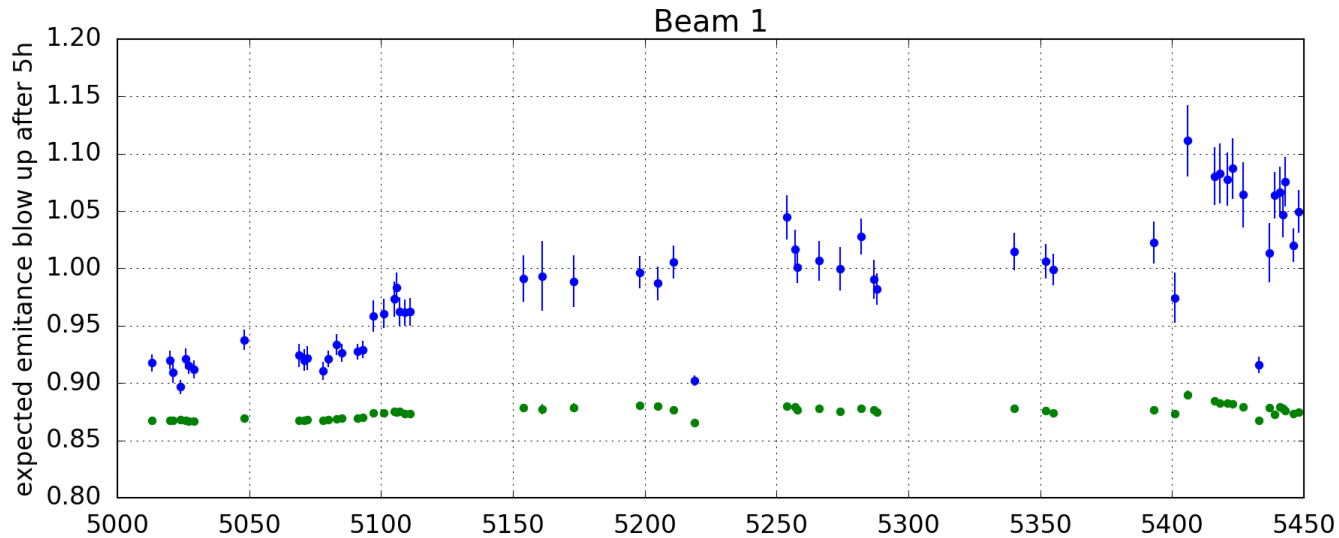

F.Antoniou, Evian 2016

- Evolution of the average normalized losses (after one hour in SB) along the run
- Beam 1 losses higher than Beam 2 losses
- Minimum losses after the transition to BCMS (Beam 2 losses become burn-off dominated)
- Increase of losses after the crossing angle change followed by an improvement trend
- Clear impact of the LHCb polarity changes

# Expected Emittance blow-up

F.Antoniou

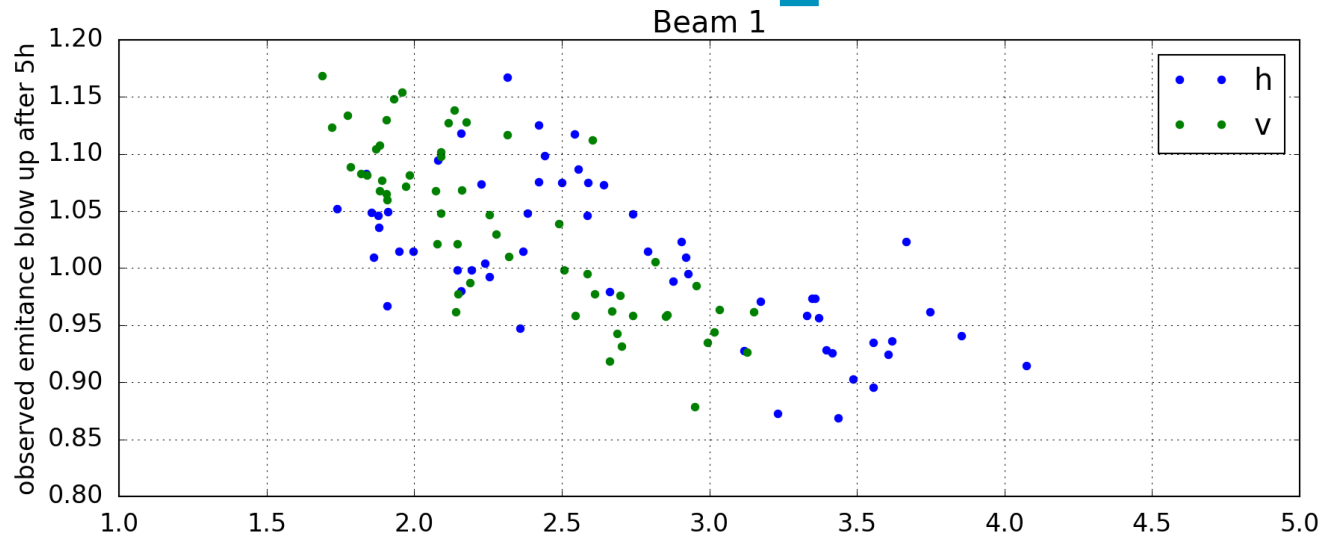

# Observed Emittance blow-up

F.Antoniou

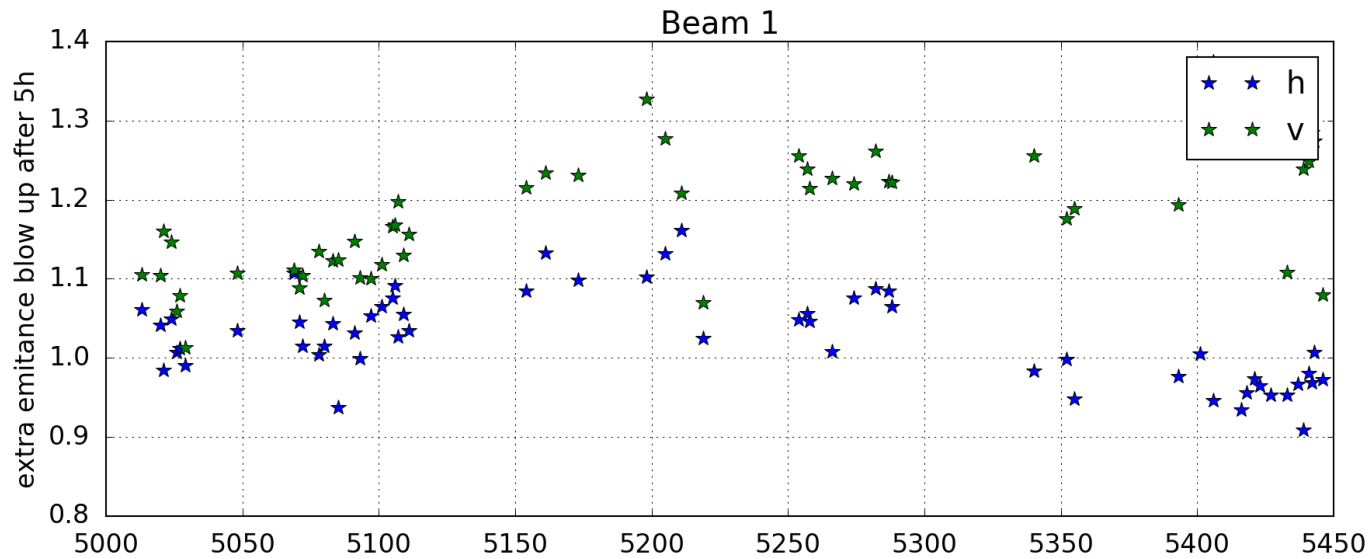

# Observed Emittance blow-up

F.Antoniou

# Extra Emittance blow-up

F.Antoniou

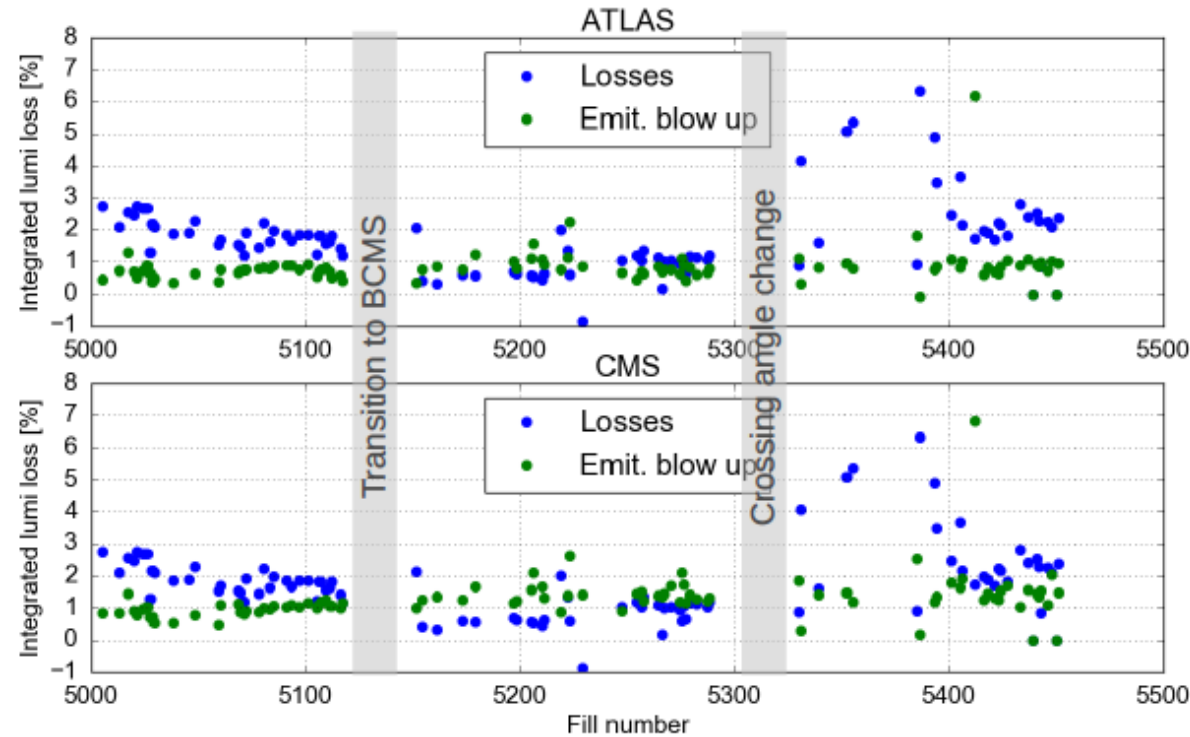

# Extra Emittance blow-up

F.Antoniou

# Luminosity loss

- The integrated luminosity over the first 3h is calculated for each model assumption
- Integrated luminosity loss due to:
  - **extra losses:**
  - **extra emittance blow up**

- Contribution of the extra **emittance blow-up** is **constant** over the year
- Contribution of extra **losses** is **sensitive to changes in the machine**

# Availability

# Remarks

- Based on observation from 2016
  - Estimate luminosity evolution for HL-LHC scenarios by assuming an extra blow-up growth rate based on the data
    - Correlated with brightness?
  - Including realistic evolution from injection to stable beams
  - Including availability observed in 2016

# Impact of LHCb polarity - octupoles

# Effect of octupoles and LHCb

- Tune scans for **550A octupole** and LHCb on with good polarity, end of levelling parameters, nominal scheme
- DA quite limited...

N. Karastathis, D. Pellegrini

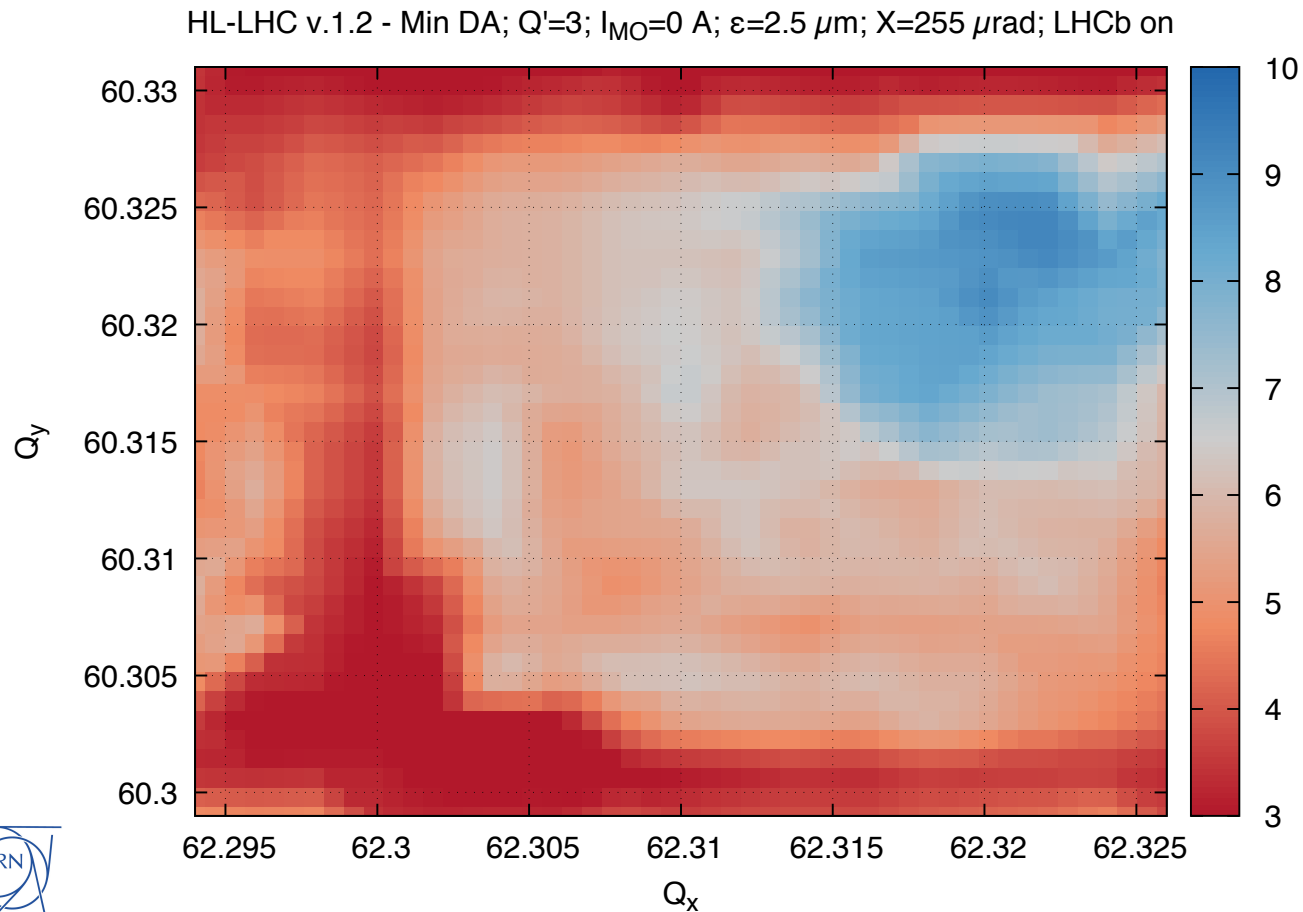

HL-LHC v.1.2 - Min DA;  $Q'=3$ ;  $I_{MO}=550$  A;  $\epsilon=2.5$   $\mu\text{m}$ ;  $X=255$   $\mu\text{rad}$ ; LHCb on

# Effect of octupoles and LHCb

- Tune scans for **0 octupole** and LHCb on with good polarity, end of levelling parameters, nominal scheme
- Recovering DA towards the diagonal

N. Karastathis, D. Pellegrini

# Effect of octupoles and LHCb

- Tune scans for **-550 octupole** and LHCb **off**, end of levelling parameters, nominal scheme
- DA even more improved

N. Karastathis, D. Pellegrini

# Effect of octupoles and LHCb

- Tune scans for **-550 A octupole** and LHCb **on**, with “**good polarity**” end of levelling parameters, nominal scheme
- DA degraded especially close to 3<sup>rd</sup> and 10<sup>th</sup> order resonances

N. Karastathis, D. Pellegrini

# Effect of octupoles and LHCb

- Tune scans for **-550 A octupole** and LHCb **on**, with “**bad polarity**” end of levelling parameters, nominal scheme
- DA degraded mostly close to 10<sup>th</sup> order resonances

N. Karastathis, D. Pellegrini

# Summary

***Thanks for your attention***
