I. Altarev et al., , arXiv:1501.07861, J. Appl. Phys. (2015), Applir Phys.-Lietto (2015) eting CERN March 13th 2017

Magnetometer stability is not trivial: e.g. SQUID and He+Xe cell

Illustration: simultaneous precession of ¹²⁹Xe and ³He amplitude in cylindrical cell with 5 kV/cm applied (preliminary data for illustration only!)

Many new systematic effects observed at this level of precision: EDM experiments are difficult...

III Side note: Progress with SQUIDs

FIG. 1. Left: the schematic setup of LINOD2 in gradiometer configuration. Right: a view of one of the heat shields made from Al_2O_3 strips together with the copper mesh heat shield at the dewar reservoir. The outer shell has been removed.

пп

FIG. 2. Measured magnetic flux density noise $S_{B,m}^{1/2}$ for the two setups with 45 mm diameter pick-up coils: Magnetometer (solid green curve) and gradiometer (solid blue curve). The calculated intrinsic SQUID noise levels $S_{B,i}^{1/2}$ are given by the dotted curves. For the gradiometer, the noise is referred to the bottom pick-up loop, and the gradient noise is shown on the right.

PTB BERLIN: Appl. Phys. Lett. 110, 072603 (2017)

Improved magnetic equilibration

Ultra low magnetic fields and gradients: ,L-shaped' coils, 10 x improved speed to state of the art, also better result

Time-dependent simulations of hysteresis curves

Current status: Quantitatively correct time-dependent modeling of real geometries

I Implications (examples)

Residual fields in shielded rooms can be lowered and gradients minimized; Static and time-dependent simulations give quite different results:

B inside the shield before and after equilibration

Z. Sun (HIT), in collaboration with TUM

A magnetic shield with new design

- New wall design
- 2 mm thick, 1 shell
- L-shaped, (NEW) distributed equilibration coils
- Installed temporarily inside outer TUM EDM shield for characterization

New: distributed equilibration coils

- Idea: keep "mistakes' close to material (similar to pEDM octagon prototype)
- Used in several new experiments and installations (e.g. at Harbin Inst. of Techn., also e.g. in atomic fountains, at ISS, and for a new PRIMORDIAL MAGNETIC FIELD experiment
- Best results: < 25 pT in 1 m³ measured at TUM with PTB and HIT (8/2016)

Residual field of new design – a typical map

P. Fierlinger – pEDM meeting CERN March 13th 2017

A simple trick for residual field modeling

Applying DC bias-currents in equilibration coils produces similar field pattern as imperfect equilibration:

Side note: MSR creator script

(free and open source)

Magnetic shields contain a logical structure. Why design this manually?

Inputs:

Number of Permalloy shields, Dimensions and holes, RF shield position, Substrates for Permalloy etc.

Output:

Full Solidworks 3D model of shields with all parts in details (screw holes, tolerances, materials)

Noise measured with SQUID:

Problems to keep in mind also for pEDM

SQUID measurements of Sussex- EDM electrodes @ PTB Berlin

> 200 pT in 3 cm distance: as used in Sussex-EDM experiment demagnetized: 20 pT pp in 3 cm distance (Larger than nEDM error budget!) Thermally induced currents in metals: MUCH more critical than Johnson noise

Next generation...

What is *really* happening in next-generation experiments?

E.g.

- Tsallis-distributions of particle spins
- Distributions can also have higher moments: possible identification of origin of false effects
 - Could also show up elsewhere? Skewness -> would lead to wrong estimation of a frequency shift?

Next generation...

Build-up of non-gaussian shape over time:

- Improvements of techniques compared to EDM shields in 2016
- Very small residual fields are possible with fast equilibration
- Johnson noise of MSRs ~ 100 aT/rt(Hz)
- Thermal currents in metallic parts will likely dominate (e.g. in electrodes!)
- High (passive) stability possible
- Gradient requirements for EDM measurements realistic
- 'Yet unknown' systematics may require even better magnetic shielding...
