Decay modes of neutral pion:

| Process                          | Branching ratio                  |
|----------------------------------|----------------------------------|
| $\pi^0 \rightarrow \gamma\gamma$ | $(98.823 \pm 0.034) \%$          |
| $\pi^0 \rightarrow e^+e^-\gamma$ | $(1.174 \pm 0.035) \%$           |
| $\pi^0 \rightarrow e^+e^+e^-e^-$ | $(3.34 \pm 0.16) \times 10^{-5}$ |
| $\pi^0 \rightarrow e^+e^-$       | $(6.46 \pm 0.33) \times 10^{-8}$ |

Rare decay  $\pi^0 \rightarrow e^+e^-$

- interesting way to study low-energy (long-distance) dynamics in the SM
- systematic theoretical treatment dates back to *Drell, NC (1959)*
- suppressed in comparison to the decay  $\pi^0 \rightarrow \gamma\gamma$  by a factor of  $2(\alpha m_e/M_\pi)^2$ 
  - one-loop structure + helicity suppression
  - may be sensitive to possible effects of new physics

### Summary

KTeV-E799-II experiment at Fermilab (*Abouzaid et al., PRD 75 (2007)*)  
→ **precise** measurements of branching ratio  $\pi^0 \rightarrow e^+e^-$  (794 candidates)

$$\frac{\Gamma(\pi^0 \rightarrow e^+e^-(\gamma), x > 0.95)}{\Gamma(\pi^0 \rightarrow e^+e^-\gamma, x > 0.232)} = (1.685 \pm 0.064 \pm 0.027) \times 10^{-4}$$

Extrapolate the Dalitz decay branching ratio to full range of  $x$

$$B^{\text{KTeV}}(\pi^0 \rightarrow e^+e^-(\gamma), x_D > 0.95) = (6.44 \pm 0.25 \pm 0.22) \times 10^{-8}$$

- PDG average value  $(6.46 \pm 0.33) \times 10^{-8}$  mainly based on this result
- extrapolate full radiative tail beyond  $x > 0.95$  (*Bergström, Z.Ph.C 20 (1983)*)
- scale the result back by the overall radiative corrections

→ **final result** for lowest order (no final state radiation)

$$B_{\text{KTeV}}^{\text{no-rad}}(\pi^0 \rightarrow e^+e^-) = (7.48 \pm 0.29 \pm 0.25) \times 10^{-8}$$

Comparison with SM prediction (*Dorokhov and Ivanov, PRD 75 (2007)*)

$$B_{\text{SM}}^{\text{no-rad}}(\pi^0 \rightarrow e^+e^-) = (6.23 \pm 0.09) \times 10^{-8}$$

→ interpreted as **3.3  $\sigma$  discrepancy** between theory and experiment

Results

Summary

- QCD describes the dynamics of **quarks** and **gluons**
- at low energy we need to describe interactions of **hadrons** (e.g. pions) instead  
→ the relevant degrees of freedom are different
- **effective** description  
→ does not need to be necessarily less precise  
→ in general, the structure at short distances (high energies) is ignored  
→ many unknown **parameters** appear (so called LECs)  
→ set from experiment or more fundamental theory (matching)
- the perturbation series is not based on the coupling  
→  $\alpha_s$  grows with the distance  
→ different **power counting** schemes - derivatives (momenta)
- $\chi$ PT answers the question **how** to construct the Lagrangian monomials  
→ Green functions satisfy the same Ward identities as in QCD

Comparison

Results

Summary

- pions are complicated **composite** objects  
→ elementary interactions are not point-like
- electromagnetic pion transition form factor  $F_{\pi^0\gamma^*\gamma^*}$  describes this complexity

- **free** parameter  $\chi^{(r)}(\mu)$  appears in the finite part of the counter term

$$\chi = [\text{UV-divergent part}] + \chi^{(r)}(\mu)$$

→ unique for every form factor, e.g.  $\chi_{\text{KTeV}}^{(r)}(M_\rho) = 6.0 \pm 1.0$

In Yang–Mills theory at  $N_c = \infty$

1) mesons (and glue states) are **free**

- meson decay amplitudes of order  $1/\sqrt{N_c}$
- meson-meson elastic scattering amplitudes of order  $1/N_c$

⇒ stable and non-interacting

2) **infinite** number of meson states

3) elastic amplitudes given as sum of **tree** diagrams

→ not quarks and gluons, but **physical mesons** are exchanged

4) Zweig's rule is **exact**

→ mesons pure  $q\bar{q}$  states

# Large $N_c$ limit

Way to derivation

Many colors  $\implies$  large **combinatoric** factors in Feynman diagrams

- gluon fields  $N_c \times N_c$  matrices in adjoint representation,  $N_c^2(-1)$  components
- quark fields have  $N_c$  components

't Hooft's double line notation

$\rightarrow$  gluons have same  $SU(N_c)$  QN as  $q\bar{q}$

combinatoric factors cancel the **vertex** factors only in planar diagrams

$\rightarrow$  large  $N_c$  limit given therefore given only by sum of **planar** diagrams

## Selection rules

- 1) in large  $N_c$  limit the **non-planar** diagrams are suppressed by factors of  $1/N_c^2$
- 2) **internal** quark loops are suppressed by factors of  $1/N_c$

# Large $N_c$ limit

Important consequence for mesons

## Examples of **other** approaches

- Vector-Meson Dominance (VMD)

$$\mathcal{F}_{\pi^0\gamma^*\gamma^*}^{\text{VMD}}(p^2, q^2) = -\frac{N_c}{12\pi^2 F} \left[ \frac{M_{V_1}^4}{(p^2 - M_{V_1}^2)(q^2 - M_{V_1}^2)} \right]$$

→ violates OPE:  $\mathcal{F}_{\pi^0\gamma^*\gamma^*}(q^2, q^2) \not\sim \frac{1}{q^2}$ ,  $q^2 \rightarrow -\infty$

- Lowest-Meson Dominance (LMD)

$$\mathcal{F}_{\pi^0\gamma^*\gamma^*}^{\text{LMD}}(p^2, q^2) = \mathcal{F}_{\pi^0\gamma^*\gamma^*}^{\text{VMD}}(p^2, q^2) \left\{ 1 - \frac{4\pi^2 F^2 (p^2 + q^2)}{N_c M_{V_1}^4} \right\}$$

→ violates BL:  $\mathcal{F}_{\pi^0\gamma^*\gamma^*}(0, q^2) \not\sim \frac{1}{q^2}$ ,  $q^2 \rightarrow -\infty$

- none of the models used two meson multiplets in both channels  
→ vector and pseudoscalar

## Theoretical prediction within THS model

$$B^{\text{THS}}(\pi^0 \rightarrow e^+e^-\gamma), x_D > 0.95 = (5.8 \pm 0.2) \times 10^{-8}$$

- recall experimental value:  $B^{\text{KTeV}} = (6.44 \pm 0.33) \times 10^{-8}$   
→ disagreement at the level of only **1.8  $\sigma$**
- matching on LO  $\chi$ PT gives  $\chi_{\text{THS}}^{(r)}(M_\rho) = 2.2 \pm 0.7$
- if KTeV result confirmed (e.g. by NA62) → two scenarios are conceivable:
  - a) some aspects of the THS approach not well-suited for  $\pi^0 \rightarrow e^+e^-$
  - b) beyond-Standard Model physics influences the rare pion decay significantly
- under the present circumstances the current discrepancy is **inconclusive**

Quantity **really** measured by KTeV

$$\frac{\Gamma(\pi^0 \rightarrow e^+e^-\gamma), x > 0.95}{\Gamma(\pi^0 \rightarrow e^+e^-\gamma(\gamma), x > 0.2319)} \Bigg|_{\text{KTeV}} = (1.685 \pm 0.064 \pm 0.027) \times 10^{-4}$$

→ Dalitz decay comes into play

- Summary

All NLO QED radiative corrections for discussed processes are now available  
→ can be taken into account in **future** experimental analyses

- $\pi^0 \rightarrow e^+e^-$

*Vaško and Novotný, JHEP 1110 (2011)*

*TH, Kampf and Novotný, EPJC 74 (2014)*

- $\pi^0 \rightarrow e^+e^-\gamma$

*TH, Kampf and Novotný, PRD 92 (2015)*

THS model for  $\mathcal{F}_{\pi^0\gamma^*\gamma^*}(p^2, q^2)$

- phenomenologically successful
- satisfies **all** main theoretical constraints
- *TH and S. Leupold, EPJC 75 (2015)*

Altogether, we get **reasonable** SM prediction

→ differs from KTeV by **1.8**  $\sigma$
