Radioactive ISOL beam production for SPIRAL 2

Thursday 10 June 2010 18:10 (15 minutes)

The future facility SPIRAL 2 at GANIL aims at producing radioactive isotopes using not only neutron induced fission from high density UCx target, but from other nuclear reactions such as deep inelastic transfer, fusion evaporation, etc [1]. The different intensity estimates for some of the beam that should be available at the start of SPIRAL 2 and their extrapolation to nominal operation conditions will be presented during the meeting together with the method adopted for calculating the in-target yield estimates, for evaluating diffusion and effusion losses, ionization, charge breeding and post-acceleration efficiencies.
