Light axion dark matter

mass $m \sim 10^{-22}$ eV

Fuzzy dark matter
Hu, Barkana, Gruzinov

- A natural candidate for such a light particle is a pseudo Goldstone boson.
- Concrete realization: an angular field of periodicity $2\pi F$ i.e. an axion-like field with a potential from non-perturbative effects (not QCD axion).

$$\mathcal{L} \sim -\frac{1}{2}(\partial\phi)^2 - \Lambda^4(1 - \cos[\phi/F])$$

$$m \sim \Lambda^2/F$$

(see Monday's talks)

- Relic abundance:

(standard story - see Kolb & Turner;
review by Marsh)

$$\Omega_{\text{matter}} \sim \left(\frac{F}{10^{17} \text{ GeV}} \right)^2 \left(\frac{m}{10^{-22} \text{ eV}} \right)^{1/2}$$

(low scale inflation)

Dynamics of a free massive scalar

- Ignoring self-interaction:

$$-\square\phi + m^2\phi = 0$$

$$m^{-1} \sim 0.06 \text{ pc}$$

$$(mv)^{-1} \sim 2 \text{ kpc } (10 \text{ km s}^{-1}/v)$$

- Non-relativistic limit:

$$\phi = \frac{1}{\sqrt{2m}} [\psi e^{-imt} + \psi^* e^{imt}]$$

$$|\ddot{\psi}| \ll m|\dot{\psi}| \longrightarrow i\dot{\psi} = \left[-\frac{\nabla^2}{2m} + m\Phi_{\text{grav.}} \right] \psi$$

- High occupancy implies ψ should be thought of as a classical scalar. See simulations by Hsi-Yu Schive, Tzihong Chiueh & Tom Broadhurst.
- An alternative viewpoint: ψ as a (classical) fluid.

$$\rho = m|\psi|^2 \quad \text{i.e.} \quad \psi = \sqrt{\rho/m} e^{i\theta}$$

Recall conservation of probability: current $\propto i(\psi\nabla\psi^* - \psi^*\nabla\psi)$

Reinterpreted as conservation of mass:

$$\dot{\rho} + \nabla \cdot \rho v = 0 \quad \text{where} \quad v = \frac{1}{m} \nabla \theta \quad \text{i.e. a superfluid.}$$

Fluid formulation (Madelung)

- Euler equation:

$$\dot{v} + v \cdot \nabla v = -\nabla \Phi_{\text{grav.}} + \frac{1}{2m^2} \nabla \left(\frac{\nabla^2 \sqrt{\rho}}{\sqrt{\rho}} \right)$$

↑
“quantum pressure”

- More precisely, an unusual form of stress:

$$T_{ij} = \rho v_i v_j + \frac{1}{2m^2} [\partial_i \sqrt{\rho} \partial_j \sqrt{\rho} - \sqrt{\rho} \partial_i \partial_j \sqrt{\rho}]$$

- Can be implemented in standard hydrodynamics codes (Mocz & Succi).
- For linear perturbations (on cosmological bgd.):

$$\text{Jeans scale} \sim 0.1 \text{ Mpc}$$

Perturbations suppressed on small scales - could help avoid small scale problems of standard CDM (Hu, Barkana, Gruzinov: **Fuzzy DM**; Amendola, Barbieri).

Typical focus: density profile (cusp versus core), number of satellite galaxies.

Issue: baryonic effects make it hard to draw definitive conclusions.

The unexpected diversity of dwarf galaxy rotation curves

ABSTRACT

We examine the circular velocity profiles of galaxies in Λ CDM cosmological hydrodynamical simulations from the EAGLE and LOCAL GROUPS projects and compare them with a compilation of observed rotation curves of galaxies spanning a wide range in mass. The shape of the circular velocity profiles of simulated galaxies varies systematically as a function of galaxy mass, but shows remarkably little variation at fixed maximum circular velocity. This is especially true for low-mass dark matter-dominated systems, reflecting the expected similarity of the underlying cold dark matter haloes. This is at odds with observed dwarf galaxies, which show a large diversity of rotation curve shapes, even at fixed maximum rotation speed. Some dwarfs have rotation curves that agree well with simulations, others do not. The latter are systems where the inferred mass enclosed in the inner regions is much lower than expected for cold dark matter haloes and include many galaxies where previous work claims the presence of a constant density “core”. The “cusp vs core” issue is thus better characterized as an “inner mass deficit” problem than as a density slope mismatch. For several galaxies the magnitude of this inner mass deficit is well in excess of that reported in recent simulations where cores result from baryon-induced fluctuations in the gravitational potential. We conclude that one or more of the following statements must be true: (i) the dark matter is more complex than envisaged by any current model; (ii) current simulations fail to reproduce the diversity in the effects of baryons on the inner regions of dwarf galaxies; and/or (iii) the mass profiles of “inner mass deficit” galaxies inferred from kinematic data are incorrect.

Dynamical friction issue: Tremaine 1976

Dynamical friction

- Chandrasekhar's classic calculation:

- Quantum stress smooths out density wake, lowering friction. (see also Lora et al.)
- Use known solution for the Coulomb scattering problem:
$$\psi \propto F [i\beta, 1, ikr(1 - \cos \theta)]$$
 where F is the confluent hypergeometric func.
$$\beta \equiv (GM/v^2)/k^{-1}$$
 with $k^{-1} = (mv)^{-1} = \text{de Broglie wavelength}$

Small β means quantum stress is important.

- **Key** - integrate momentum flux to compute friction: $\oint dS_j T_{ij}$

Question: shouldn't the quantum and classical answers be identical?

Recall that for Coulomb differential cross section,
quantum = classical.

- But recall also the integrated cross section has a logarithmic divergence.
- Thus, we expect dynamical friction $\propto \ln [r/r_c]$ where $r \sim$ size of galaxy,
 $r_c \sim GM/v^2$ or k^{-1}
- This is borne out by analytic calculation, made possible by obscure identities involving hypergeometric functions.

$$\beta \equiv (GM/v^2)/k^{-1}$$

$$= 0.0023 \left(\frac{M}{10^5 M_{\odot}} \right) \left(\frac{10 \text{ km/s}}{v} \right) \left(\frac{m}{10^{-22} \text{ eV}} \right)$$

Conclusion:

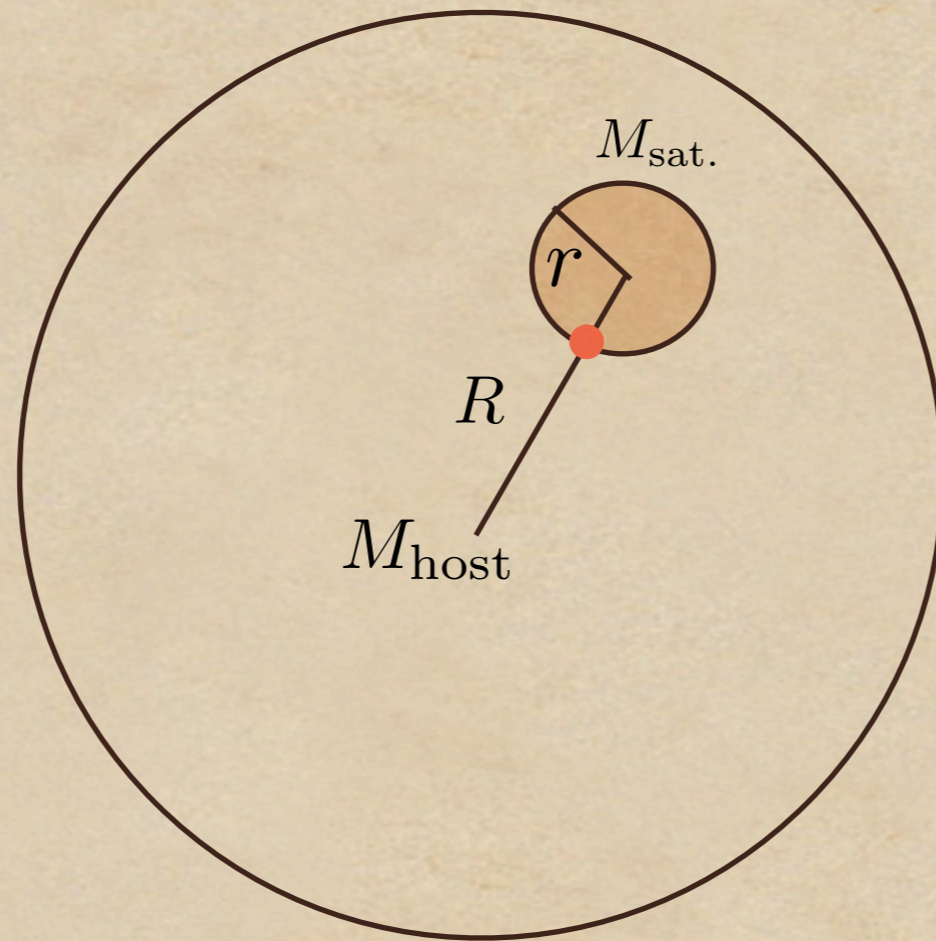

Given the density profile of a galaxy (which can be experimentally determined), standard CDM has a definite prediction for the dynamical friction, which can be checked against observations.

Fuzzy DM of $m \sim 10^{-22}$ eV can lower dynamical friction by an order of magnitude.

Would be useful to study other systems: Lotz et al. 2001

Possible diagnostics of FDM vs conventional CDM:

- dynamical friction ✓
- evaporation of sub-halos by tunneling
- interference
- tidal streams and gravitational lensing
- Lyman-alpha forest
- direct detection
- detection by pulsar timing array

Recall tidal disruption: $\frac{GM_{\text{host}}}{R^2} \frac{r}{R} \sim \frac{GM_{\text{sat.}}}{r^2}$

$r =$ disruption radius

Quantum pressure is expected to alter this.

$M_{\text{satellite}} > 10^8 M_{\odot}$ in Milky Way

Figure 2: A slice of density field of ψ DM simulation on various scales at $z = 0.1$. This scaled sequence (each of thickness 60 pc) shows how quantum interference patterns can be clearly seen everywhere from the large-scale filaments, tangential fringes near the virial boundaries, to the granular structure inside the haloes. Distinct solitonic cores with radius $\sim 0.3 - 1.6$ kpc are found within each collapsed halo. The density shown here spans over nine orders of magnitude, from 10^{-1} to 10^8 (normalized to the cosmic mean density). The color map scales logarithmically, with cyan corresponding to density $\lesssim 10$.

FIG. 11: The best fit model for the MIKE data set (black crosses) used in the present analysis, shown as the green curves and labelled as “ Λ CDM b.f.”. This model is very close to Λ CDM. We also show for qualitative purposes a few other models: a WDM model that has the same parameters as the best fit model except for the WDM mass (red curves) which is chosen to be 2.5 keV; a model that has a hotter temperature (orange curves) and a model for which the mass of the WDM is fixed to $m_{\text{WDM}} = 2.5$ keV, but for which all other parameters are set to their best-fitting values for this choice (blue curves). Note that for the MIKE data we do not use the $z = 5.4$ redshift bin.

Naive translation : $m_{\text{WDM}} \sim 2.5 \text{ keV} \rightarrow m_{\text{FDM}} \sim 10^{-21} \text{ eV}$

- But :
- allowing non – monotonic thermal history relaxes WDM mass bound by 1 keV (Garzilli et al.)
 - fluctuations in the ionizing background and reionization history could be important
 - granularity of FDM might be non – negligible

The impact of feedback from galaxy formation on the Lyman- α transmitted flux

ABSTRACT

The forest of Lyman- α absorption lines seen in the spectra of distant quasars has become an important probe of the distribution of matter in the Universe. We use large, hydrodynamical simulations from the OWLS project to investigate the effect of feedback from galaxy formation on the probability distribution function and the power spectrum of the Lyman- α transmitted flux. While metal-line cooling is unimportant, both galactic outflows from massive galaxies driven by active galactic nuclei and winds from low-mass galaxies driven by supernovae have a substantial impact on the flux statistics. At redshift $z = 2.25$, the effects on the flux statistics are of a similar magnitude as the statistical uncertainties of published data sets. The changes in the flux statistics are not due to differences in the temperature-density relation of the photoionised gas. Instead, they are caused by changes in the density distribution and in the fraction of hot, collisionally ionised gas. It may be possible to disentangle astrophysical and cosmological effects by taking advantage of the fact that they induce different redshift dependencies. In particular, the magnitude of the feedback effects appears to decrease rapidly with increasing redshift. Analyses of Lyman- α forest data from surveys that are currently in process, such as BOSS/SDSS-III and X-Shooter/VLT, must take galactic winds into account.

FIG. 9.— Convergence test for the box size, force resolution and particle mass. We show the power spectrum of the Ly α forest flu $\Delta_{\text{F},1\text{d}}^2(k)$ averaged over all realizations for the three sets of simulation with different box sizes and particle masses. In this case output was on the lightcone, but the radiation output of quasars was set to be isotropic. The top panel shows the fractional difference (Eqn. 16) in $\Delta_{\text{F}}^2(k)$ between the raytraced simulation and that using a uniform radiation field.

FIG. 3: Axion parameter space, (m, g_N) . The QCD axion paired with the ULA is shown for reference, along with the specific point $f_{\text{QCD}} = 10^{11}$ GeV, which is our reference value. BHSR excludes a range of masses at 2σ independent of DM abundance and coupling strength [76]. SN1987A excludes the shaded region with $g_N \gtrsim 8.2 \times 10^{-10}$, independent of DM abundance and axion mass [79]. The region both allowed and detectable using cosmology, and relevant to the small-scale crises of CDM is $10^{-22} \text{ eV} \lesssim m \lesssim 10^{-18} \text{ eV}$ [24–26, 28–30]. We show the \mathbf{Z}_N models in this regime only, and also show the target region where f_{ULA} allows for the ULAs to be the dominant form of DM without fine tuning. The region accessible to direct detection using the spin precession technique of CASPER-Wind [34, 35] is also shown. The cosmologically relevant regime of the \mathbf{Z}_N models lies well within the projected sensitivity of CASPER-Wind, and is not excluded by any other probes.

ABSTRACT: An ultralight free scalar field with mass around $10^{-23} - 10^{-22}$ eV is a viable dark matter candidate, which can help to resolve some of the issues of the cold dark matter on sub-galactic scales. We consider the gravitational field of the galactic halo composed out of such dark matter. The scalar field has oscillating in time pressure, which induces oscillations of gravitational potential with amplitude of the order of 10^{-15} and frequency in the nanohertz range. This frequency is in the range of pulsar timing array observations. We estimate the magnitude of the pulse arrival time residuals induced by the oscillating gravitational potential. We find that for a range of dark matter masses, the scalar field dark matter signal is comparable to the stochastic gravitational wave signal and can be detected by the planned SKA pulsar timing array experiment.

Average shear vanishes, but rms shear builds up in a random walk.

$$\text{rms shear of tidal stream} \sim N^{3/2} R^{-1} \int d^2 k_{\perp} P_{\delta}(k_{\perp})$$

where R = orbital radius, N = no. of orbits,
 P_{δ} = substructure power spectrum

Carlberg 2009

FIG. 1.— Face on views of a time sequence within one simulation. A range of stream locations are sampled with ten rings with 1000 particles per ring. These idealized streams are initiated on purely circular orbits which would preserve their appearance in the absence of sub-halos. The time is shown in Gyr indicated in the lower right of each sub-panel. The plotted radii are the arctangent of the r_{max} scaled radii to allow a more uniform display. Note how a wave-like perturbation evolves into a z-fold which gradually leads to a scrambling of the ring.
