October, 2007

Abstract. We present the new and updated *BABAR* measurements of CP -violation studies for many $b \rightarrow s$ penguin decay modes. We report the first observation of mixing-induced CP -violation in $B^0 \rightarrow \eta' K^0$ with a significance (including systematic uncertainties) of 5.5σ . We also present the first observation of the decay $B^0 \rightarrow \rho^0 K^0$. Using the time-dependent Dalitz plot analysis of $B^0 \rightarrow K^+ K^- K^0$ decay, the CP -parameters \mathcal{A}_{CP} and β_{eff} are measured with 4.8σ significance, and we reject the solution near $\pi/2 - \beta_{eff}$ at 4.5σ . We also present the updated measurements of CP -violating parameters for $B^0 \rightarrow K_S^0 \pi^0$, $K_S^0 K_S^0 K_S^0$ and $\pi^0 \pi^0 K_S^0$ decays. An updated measurements of the CP -violating charge asymmetries for $B^\pm \rightarrow \eta' K^\pm$, ηK^\pm , ωK^\pm decays are also presented. The measurements are based on the data sample recorded at the $\Upsilon(4S)$ resonance with *BABAR* detector at the PEP-II B -meson Factory at SLAC.

1 Introduction

Measurements of time-dependent CP -asymmetries in B^0 meson decays through Cabibbo-Kobayashi-Maskawa (CKM) favoured $b \rightarrow c\bar{c}s$ amplitudes [1] have provided crucial tests of the mechanism of CP -violation in the standard model (SM) [2]. A major goal of B Factory experiments is now to search for indirect evidence for New Physics (NP). One strategy is to compare the measured value of the CP -violation (CPV) parameters from $b \rightarrow c\bar{c}s$ to independent determinations of the same quantities, from processes that are sensitive to the contributions of NP effects through loop (penguin) diagrams. In the decay chain $\Upsilon(4S) \rightarrow B^0 \bar{B}^0$, one of the two B mesons decays into a CP eigenstate f_{CP} at time t_{CP} , and other decays into a flavor specific state f_{tag} at time t_{tag} . The CPV parameters are measured using time-dependent decay rate

$$\mathcal{P}(\Delta t) = \frac{e^{-|\Delta t|/\tau}}{4\tau} \times [1 + q\{S_f \sin(\Delta m_d \Delta t) - C_f \cos(\Delta m_d \Delta t)\}] \quad (1)$$

where $\Delta t = t_{CP} - t_{tag}$, τ is the B lifetime, Δm_d is the $B^0 \bar{B}^0$ mixing frequency and $q = +1(-1)$ when $f_{tag} = B^0(\bar{B}^0)$. The parameters S_f and C_f represent the mixing-induced and direct CPV respectively. For penguin-dominated processes $b \rightarrow sq\bar{q}$ ($q = u, d, s$), S_f and C_f are expected to be consistent with the values from $b \rightarrow c\bar{c}s$ decays (namely, $C_f \sim 0$ and $S_f \sim \sin 2\beta$). Additional CKM suppressed contribu-

tions to the amplitude can induce only small deviations from the expectation. On the other hand, additional loop contributions from NP processes may produce large observable deviations [3]. In this paper, we present new and updated measurements of $b \rightarrow s$ penguin decays.

2 Analysis Overview

The updated and new measurements presented here are based on the data collected with the *BABAR* detector [4] at the PEP-II asymmetric energy e^+e^- collider, located at SLAC, USA. Unless explicitly stated, all the analyses are presented with a data sample corresponds to 383 ± 4 million $B\bar{B}$ pairs recorded at $\Upsilon(4S)$ resonance (Center-of-mass energy (CM) $\sqrt{s} = 10.58$ GeV) and $37 fb^{-1}$ data collected about 40 MeV below the $\Upsilon(4S)$ resonance (“off-resonance”). The *BABAR* detector provides the charged particle tracking through a combination of a 5-layer silicon vertex tracker (SVT) and a 40-layer drift chamber (DCH), both operating within a 1.5 T magnetic field generated by a superconducting solenoidal magnet. Photons are identified in an electromagnetic calorimeter (EMC) surrounding a detector of internally reflected Cherenkov light (DIRC), which associates Cherenkov photons with tracks for particle identification (PID). Muon candidates are identified with the use of the instrumented flux return (IFR) of the solenoid.

To discriminate between signal and background, two independent kinematic variables, the beam energy substituted mass $m_{ES} \equiv \sqrt{s/4 - (p_B^*)^2}$ and energy difference $\Delta E \equiv E_B^* - \sqrt{s}/2$ are used. Here E_B^* and

^a Email: nitesh@slac.stanford.edu

p_B^* are the CM energy and 3-momentum of B candidate, respectively. For signal decays, m_{ES} (ΔE) peak at nominal B -mass (at zero) with a resolution of a few (a few tens of) MeV. We use event topology to reject the continuum background (arises primarily from random combinations of particles in $e^+e^- \rightarrow q\bar{q}$ events ($q = u, d, s, c$) events which have a “jet-like” structure against the real B events which are more uniform. To improve the signal-background separation, some of these variables are combined in a multivariate algorithm (a Fisher discriminant or Neural Network etc.) which is trained on the signal monte carlo and $q\bar{q}$ background and used in the fits.

The physical quantities (e.g. signal yields or CP -parameters) are determined from extended and unbinned maximum likelihood (ML) fits. The likelihood function include the probability density functions (PDF) whose shapes are based on MC or data (sidebands or off-resonance). Their most important parameters are left free. In addition to signal and continuum, B -background categories are also included in the fits. Then we calculate the systematic errors arising from several sources e.g. variation of signal PDF shape parameters within their errors, B -background estimation, the effect of interference etc. In all the reported measurements of CP -violation below, the statistical errors dominates.

3 Results

3.1 $B^0 \rightarrow \eta' K^0$

Theoretically, it has the large Branching Fractions (65×10^{-6}) as compared to other penguin decay modes. Here we update our previous measurements. In addition to the $B^0 \rightarrow \eta' K_S^0$ decays used previously, we now also include the decay $B^0 \rightarrow \eta' K_L^0$. The B -daughter candidates are reconstructed through their decays $\pi^0 \rightarrow \gamma\gamma$, $\eta \rightarrow \gamma\gamma(\eta\gamma\gamma)$, $\eta \rightarrow \pi^+\pi^-\pi^0(\eta_{3\pi})$, $\eta' \rightarrow \eta\gamma\pi^+\pi^-$, $\eta' \rightarrow \eta_{3\pi}\pi^+\pi^-$, $\eta' \rightarrow \rho^0\gamma$. Only $\eta' \rightarrow \eta\gamma\pi^+\pi^-$ mode is used for the $\eta' K_L^0$. The detail of this analysis is described in Ref. [6]. We obtain the CPV parameters and signal yields for each channel from a ML fit with the input observables ΔE , m_{ES} , $Fisher$ and Δt . Finally we obtain the CP -violations parameters, $S = 0.58 \pm 0.10 \pm 0.03$ and $C = -0.16 \pm 0.07 \pm 0.03$. The data used is 2.1 times as large as that of previous measurements [5]. We observe mixing-induced CP -violation in $B^0 \rightarrow \eta' K^0$ decay with a significance of 5.5 standard deviations (systematic uncertainties included). The results for direct CP -violation is 2.1 standard deviations from zero.

3.2 $B^0 \rightarrow \rho^0 K^0$

This analysis is reported with the $227 \times 10^6 B\bar{B}$ pairs. We take a quasi-two body approach, restricting ourselves to the region of the $B^0 \rightarrow \pi^+\pi^-K_S^0$ Dalitz plot (DP) dominated by the ρ^0 and treating other $B^0 \rightarrow$

$\pi^+\pi^-K_S^0$ contributions as a non-interfering background. The effects of interference with other resonances are estimated and taken as a systematic uncertainties. The B^0 candidates are reconstructed from the combinations of $\rho^0 \rightarrow \pi^+\pi^-$ and $K_S^0 \rightarrow \pi^+\pi^-$. An unbinned extended ML fit with the input of m_{ES} , ΔE , NN , $\cos\theta_{\pi^+}$, $m_{\pi\pi}$, Δt is used to extract the CP -asymmetry and branching fractions; here NN is the neural network to enhance discrimination between signal and continuum background, $\cos\theta_{\pi^+}$ is the angle between the K_S^0 and the π^+ from the ρ^0 in the ρ^0 meson's CM frame and $m_{\pi\pi}$ is the mass of pion pairs. The fit yields 111 ± 19 signal events, we calculate the Branching Fractions ($B^0 \rightarrow \rho^0 K^0$) = $(4.9 \pm 0.8 \pm 0.9) \times 10^{-6}$, where the first error is statistical and the second systematic. The likelihood ratio between the fit result of 111 signal events and the null hypothesis of zero signal shows that this excluded at the 8.0σ level. When additive systematic effects are included, we exclude the null hypothesis at the 5.0σ level. This is the first observation of the $B^0 \rightarrow \rho^0 K^0$. The fit for the CP -parameters gives $S = 0.20 \pm 0.52 \pm 0.24$ and $C = 0.64 \pm 0.41 \pm 0.20$. The detail of this analysis can be seen at Ref. [7].

3.3 $B^0 \rightarrow K^+K^-K^0$

Previous measurements of CP -asymmetries in $B^0 \rightarrow K^+K^-K^0$ have been performed separately for the events K^+K^- in the ϕ mass region, and for events excluding the ϕ region, neglecting interference effects among intermediate states [8]. But now we have performed a time-dependent Dalitz plot analysis of $B^0 \rightarrow K^+K^-K^0$ decay from which we extract the values of CP -violation parameters by taking into account the complex amplitudes describing the entire B^0 and \bar{B}^0 Dalitz plots. We define the complex amplitude \mathcal{A} for B^0 decay as a sum of isobar amplitudes [9],

$$\begin{aligned} \mathcal{A}(m_{K^+K^-}, \cos\theta_H) &= \sum_r \mathcal{A}_r \\ &= \sum_r c_r (1 + b_r) e^{i(\phi_r + \delta_r)} \cdot f_r(m_{K^+K^-}, \cos\theta_H), \end{aligned} \quad (2)$$

where the parameters c_r and ϕ_r are the magnitude and phase of the amplitude of the component r , and we allow for different isobar coefficients for B^0 decays through the asymmetry parameters b_r and δ_r . Similarly, we can write the amplitude $\bar{\mathcal{A}}$ for \bar{B}^0 by replacing the plus signs with minus signs in above equation. Our isobar model includes resonant amplitudes ϕ , f_0 , $\chi_{c0}(1P)$, and $X_0(1550)$ [10]; non-resonant terms; and incoherent terms of B^0 decay to D^-K^+ and $D_s^-K^+$. For each resonant term, the function $f_r = F_r \times T_r \times Z_r$ describes the dynamical properties, where F_r is the Blatt-Weisskopf centrifugal barrier factor for the resonance decay vertex [11], T_r is the resonant mass line shape, and Z_r describes the angular distribution in the decay [12]. The CP -asymmetries parameters $A_{CP,r}$ (Rate Asymmetry) and $\beta_{eff,r}$ (Phase asym-

Table 1. The fit fractions \mathcal{F}_r from the fit to the full $B^0 \rightarrow K^+K^-K^0$ Dalitz Plot. Errors are statistical only.

$f_0 K^0$	40.2 ± 9.6
$X_0(1550)K^0$	4.1 ± 1.3
$(K^+K^0K^-)_{NR}$	112.0 ± 14.9
$\chi_{c0}(1P)K^0$	3.0 ± 1.2

Table 2. The CP -asymmetries for $B^0 \rightarrow K^+K^-K^0$ for the entire DP, in the high mass region, and for ϕK^0 and $f_0 K^0$ in the low mass region. The first errors are statistical and second errors are systematics.

	A_{CP}	β_{eff} (rad.)
Whole DP	$-0.015 \pm 0.077 \pm 0.053$	$0.352 \pm 0.076 \pm 0.026$
High-mass	$-0.054 \pm 0.102 \pm 0.060$	$0.436 \pm 0.087^{+0.055}_{-0.031}$
ϕK^0	$-0.08 \pm 0.18 \pm 0.04$	$0.11 \pm 0.14 \pm 0.06$
$f_0 K^0$	$0.41 \pm 0.23 \pm 0.07$	$0.14 \pm 0.15 \pm 0.05$

metry) can be computed as

$$A_{CP,r} = \frac{|\bar{\mathcal{A}}_r|^2 - |\mathcal{A}_r|^2}{|\bar{\mathcal{A}}_r|^2 + |\mathcal{A}_r|^2} = \frac{-2b_r}{1 + b_r^2}, \quad (3)$$

$$\beta_{eff,r} = \beta + \delta_r \quad (4)$$

We first extract the values of the parameters of the amplitude model, and measure the average CP -asymmetry in $B^0 \rightarrow K^+K^-K^0$ decay over the entire Dalitz plot. The fraction of events (\mathcal{F}_r) obtained from the fit to whole Dalitz plot are shown in Table 1, and the CP -asymmetries results are summarised in Table 2. The sum of the fractions is greater than one due to the interference. Using this model, we then measure the CP -asymmetries for ϕK^0 and $f_0 K^0$ decay channels, from a ‘‘low mass’’ analysis of events with $M_{K^+K^-} < 1.1 \text{ GeV}/c^2$. Finally, we perform a ‘‘high mass’’ analysis to determine the average CP -asymmetry for events with $M_{K^+K^-} > 1.1 \text{ GeV}/c^2$. The raw asymmetry between B^0 - and \bar{B}^0 -tagged events in (a) the low-mass region and (b) high-mass region are shown in Figure 1, and the obtained value of CP -parameters are given in Table 2. The values of β_{eff} and A_{CP} obtained from the whole DP fit are consistent with SM expectations of $\beta \simeq 0.370 \text{ rad}$, $A_{CP} \simeq 0$. The significance of CP -violation is 4.8σ , and we reject the solution near $\pi/2 - \beta$ at 4.5σ . In the fit to the low-mass region of DP, we find β_{eff} lower than the SM expectation about by 2σ while in the high-mass region CP -parameters are compatible with SM expectations and we observe CP -violation at the level of 5.1σ . The more detail of this analysis can be found in Ref. [13].

**Fig. 1.** The raw asymmetry between B^0 - and \bar{B}^0 -tagged events in (a) low-mass region and (b) the high-mass region. The curves are projections of corresponding fit results.

3.4 $B^0 \rightarrow K_S^0 \pi^0$

A precise measurement of direct CP -asymmetry and branching fraction for $B^0 \rightarrow K^0 \pi^0$ is important as it is possible to combine direct CP -asymmetries and branching fraction measurements for all the four $B \rightarrow K \pi$ modes to test precise sum rules. We have presented the updated measurement for this analysis. Since no charged particles are produced at the decay vertex of B so we determine the decay point by constraining the B production vertex to the interaction point (IP) in the plane orthogonal to the beam axis using only the $K_S^0 \rightarrow \pi^+ \pi^-$ trajectories. We account for possible biases due to the vertexing technique by comparing fits to a large simulated sample of IP-constrained (neglecting the J/ψ contribution to the vertex and using K_S^0 trajectory only) and nominal $B^0 \rightarrow J/\psi K_S^0$ events. The detailed analysis technique is discussed in Ref. [14]. We have measured the CPV parameters $C_{K_S^0 \pi^0} = 0.24 \pm 0.15 \pm 0.03$ and $S_{K_S^0 \pi^0} = 0.40 \pm 0.23 \pm 0.03$, and branching fraction $\mathcal{B}(B^0 \rightarrow K^0 \pi^0) = (10.34 \pm 0.66 \pm 0.58) \times 10^{-6}$. The first errors are statistical and the second are systematic. These values are consistent with SM predictions and the experimental value of $\sin 2\beta$; and the results supersede $BABAR$ previous measurements.

3.5 $B^0 \rightarrow K_S^0 K_S^0 K_S^0$

The decay $B^0 \rightarrow K_S^0 K_S^0 K_S^0$ is pure CP -even eigenstate and the theoretical uncertainty in the SM prediction of $\sin 2\beta_{eff}$ is less than 4%. The Ref. [15] gives the whole detail of this analysis. The whole data sample is divided into two subsamples, one where all three K_S^0 mesons decays into the $\pi^+ \pi^-$ channel ($B_{CP(+-)}$) and another where one of the K_S^0 mesons decays into the $\pi^0 \pi^0$ channel, while the other two decay into the $\pi^+ \pi^-$ channel ($B_{CP(00)}$). We form $\pi^0 \rightarrow \gamma \gamma$ candidates from pairs of photon candidates in the EMC. For each $B_{CP(+-)}$ candidate m_{ES} and ΔE are the two independent kinematical variable used while for $B_{CP(00)}$ reconstructed B^0 mass m_B and the missing mass $m_{miss} = \sqrt{(q_{e^+e^-} - \tilde{q}_B)^2}$ is used. Here \tilde{q}_B is the four-momentum of the $B_{CP(00)}$ candidate after a

mass constraint on the B^0 meson has been applied. Since no charged particles are produced at the decay vertex of B , we have applied the same technique to find the vertex as used in $B^0 \rightarrow K_S^0 \pi^0$ (explained in Section 3.4). The measured value of time-dependant CP -asymmetries, $S = -0.71 \pm 0.24 \pm 0.04$ and $C = 0.02 \pm 0.21 \pm 0.05$, where the first errors are statistical and the second systematic. The statistical correlation between S and C is -14.1%. The statistical significance of CP -violation is 2.9σ . These results agree well with the SM expectation and supersede our previous measurements.

3.6 $B^0 \rightarrow \pi^0 \pi^0 K_S^0$

The $B^0 \rightarrow \pi^0 \pi^0 K_S^0$ final state is CP -even eigen state, regardless of any resonant substructure. Just like $B^0 \rightarrow K_S^0 \pi^0$ and $B^0 \rightarrow K_S^0 K_S^0 K_S^0$ analyses, the same technique is used to find the vertex of B candidates. We measure the CP -violating asymmetries in this decay from a sample of approximately 227 million $B\bar{B}$ pairs. From an unbinned extended ML fit we obtain $S = 0.72 \pm 0.71 \pm 0.08$ and $C = 0.23 \pm 0.52 \pm 0.13$. When we fix the values of $-S$ to the average $\sin 2\beta$ measured in $b \rightarrow c\bar{c}s$ modes, and C to zero, and re-fit the data sample the negative likelihood changes by 2.2σ . The detail of this analysis is described in Ref. [16].

3.7 $B^\pm \rightarrow \eta' K^\pm, \eta K^\pm, \omega K^\pm$

The decays $B \rightarrow \eta K$ are especially interesting since they are suppressed relative to the abundant $B \rightarrow \eta' K$ decays due to destructive interference between two penguin amplitudes. We present the updated measurement of CP -violating charge asymmetries (\mathcal{A}_{ch}) for B^\pm . For $B^\pm \rightarrow f^\pm$ decays, the direct CP -violation would correspond to a non-zero charge asymmetry defined as

$$\mathcal{A}_{ch} \equiv \frac{\Gamma(B^- \rightarrow f^-) - \Gamma(B^+ \rightarrow f^+)}{\Gamma(B^- \rightarrow f^-) + \Gamma(B^+ \rightarrow f^+)} \quad (5)$$

Two decay chains are reconstructed for the $\eta(\rightarrow \gamma\gamma$ and $\rightarrow \pi^+ \pi^- \pi^0)$ and $\eta'(\rightarrow \pi^+ \pi^- \pi^0$ and $\rho^0(\rightarrow \pi^+ \pi^-)\gamma)$ candidates. Then ML fit are done separately for each decay chain; the likelihood functions (including systematic errors) are then combined to provide the charge asymmetries. We obtain the $\mathcal{A}_{ch}(B^+ \rightarrow \eta K^+) = -0.22 \pm 0.11 \pm 0.01$, $\mathcal{A}_{ch}(B^+ \rightarrow \eta' K^+) = 0.010 \pm 0.022 \pm 0.006$ and $\mathcal{A}_{ch}(B^+ \rightarrow \omega K^+) = -0.01 \pm 0.07 \pm 0.01$. We find no clear evidence for direct CP -violation charge asymmetries in these decays. The detail of this analysis can be found in Ref. [17].

4 Conclusion

We presented new and updated CP -violation studies for many $b \rightarrow s$ penguin decay modes. We reported the first observation of mixing-induced CP -violation in $B^0 \rightarrow \eta' K^0$ with a significance (including

systematic uncertainties) of 5.5σ . We also presented the first observation of the decay $B^0 \rightarrow \rho^0 K^0$ and a measurement of CP -violating parameters. Using time-dependent Dalitz plot analysis of $B^0 \rightarrow K^+ K^- K^0$ decay, the \mathcal{A}_{CP} and β_{eff} are measured. The significance of CP -violation is 4.8σ , and we reject the solution near $\pi/2 - \beta_{eff}$ at 4.5σ . We have also presented the updated measurements of CP -violating parameters for $B^0 \rightarrow K_S^0 \pi^0$, $K_S^0 K_S^0 K_S^0$ and $\pi^0 \pi^0 K_S^0$ decays. All results supersede previous *BABAR* results. Finally, an updated measurements of the CP -violating charge asymmetries for $B^\pm \rightarrow \eta' K^\pm, \eta K^\pm, \omega K^\pm$ decays are presented. The individual results of $S \sim \sin 2\beta_{eff}$ are consistent with world average of $\sin 2\beta$ from $b \rightarrow c\bar{c}s$ but naive average of $\sin 2\beta_{eff}$ from all penguin modes is lower than $\sin 2\beta$ [18] which is opposite to theoretical prediction. Finally, we do not find any evidence of direct CP -violation in the decay modes reported.
