

CERN SUMMER STUDENT - LECTURE I

[TERESA.MONTARULI@UNIGE.CH](mailto:TERESA.MONTARULI@UNIGE.CH)

---

# ASTROPARTICLE II

20 JULY 2017

# CONTENTS OF TWO LECTURES

- ▶ Radiation from the universe and cosmic rays (CR)
- ▶ Cosmic ray observables: spectrum and composition
- ▶ Propagation and sources of cosmic rays
- ▶ The connection of CRs to other messengers :
- ▶ CRs with Ultra-High Energy CRs
  - ▶ Gamma-Rays
  - ▶ Neutrinos

# THE MESSENGER PROPAGATION

AGN, SNRs, GRBs,...

black hole

● **GAMMA-RAYS** point to their sources but are absorbed and have multiple emission mechanisms. Also produced by leptonic acceleration, inverse Compton and synchrotron emission

● **NEUTRINOS**

They are neutral and weak particles: point to the source carrying information from the deepest parts.

● **COSMIC RAYS**

Deflected by magnetic fields  
( $E < 10^{19}$  eV)

air shower

Earth

# THE INTERACTION LENGTH OF A PARTICLE

- ▶ Horizon = messenger mean free path (interaction length) in a medium
- ▶ X-section  $\sigma$ : area of the target intercepted by a beam measured as average fraction of scattered particles per unit time in the solid angle  $d\Omega$  per unity of incident flux

$$\frac{d\sigma(E, \Omega)}{d\Omega} = \frac{1}{\Phi} \frac{dN_s}{d\Omega}$$

- ▶ Mean free path :

$w$  = interaction probability =  $N\sigma dx$ , where  $N$  = n. of target particles/Volume

$P(x)$  = prob. that a particle does not interact after traveling a distance  $x$

$P(x + dx) = P(x) (1-wdx) =$  prob. that a particle has no interaction between  $x$  and  $x+dx$

$$P(x + dx) = P(x) + \frac{dP}{dx}dx = P(x) - P(x)wdx \Rightarrow \frac{dP}{P} = -wdx \Rightarrow P(x) = P(0)e^{-wx}$$

$$\lambda = \frac{\int xP(x)dx}{\int P(x)dx} = \frac{1}{w} = \frac{1}{N\sigma} = \frac{Am_p}{\sigma\rho}$$

Target material

Particle properties

$P(0) = 1$  initially the particle did not interact

# THE MESSENGER HORIZON = INTERACTION LENGTH IN THE COSMOS

Proton horizon (GZK cut-off):

$$L_\gamma = \frac{1}{\sigma_{p-\gamma} n_\gamma} \sim 10 \text{ Mpc}$$

$$\sim \frac{1}{10^{-28} \text{ cm}^2 \times 400 \text{ cm}^{-3}}$$

The neutrino horizon is comparable to the observable universe!

$$L_\nu = \frac{1}{\sigma_{res} \times n} = \frac{1}{5 \times 10^{31} \text{ cm}^2 \times 112 \text{ cm}^{-3}} \approx 6 \text{ Gpc}$$

# ACCELERATORS

## Large Hadron Collider:

$$E_{\max} = c \cdot e \cdot B \cdot R = 7 \times 10^{12} \text{ eV}$$

9593 superconducting magnets at  $-271.3 \text{ }^\circ\text{C}$  accelerate protons to collide in 4 points instrumented to analyze matter and its constituents in which it decomposes at these extreme conditions similar to  $3 \times 10^{-15}$  seconds after the Big Bang (15 TeV correspond to abt.  $10^{17}$  Kelvin)

# COSMIC ACCELERATORS

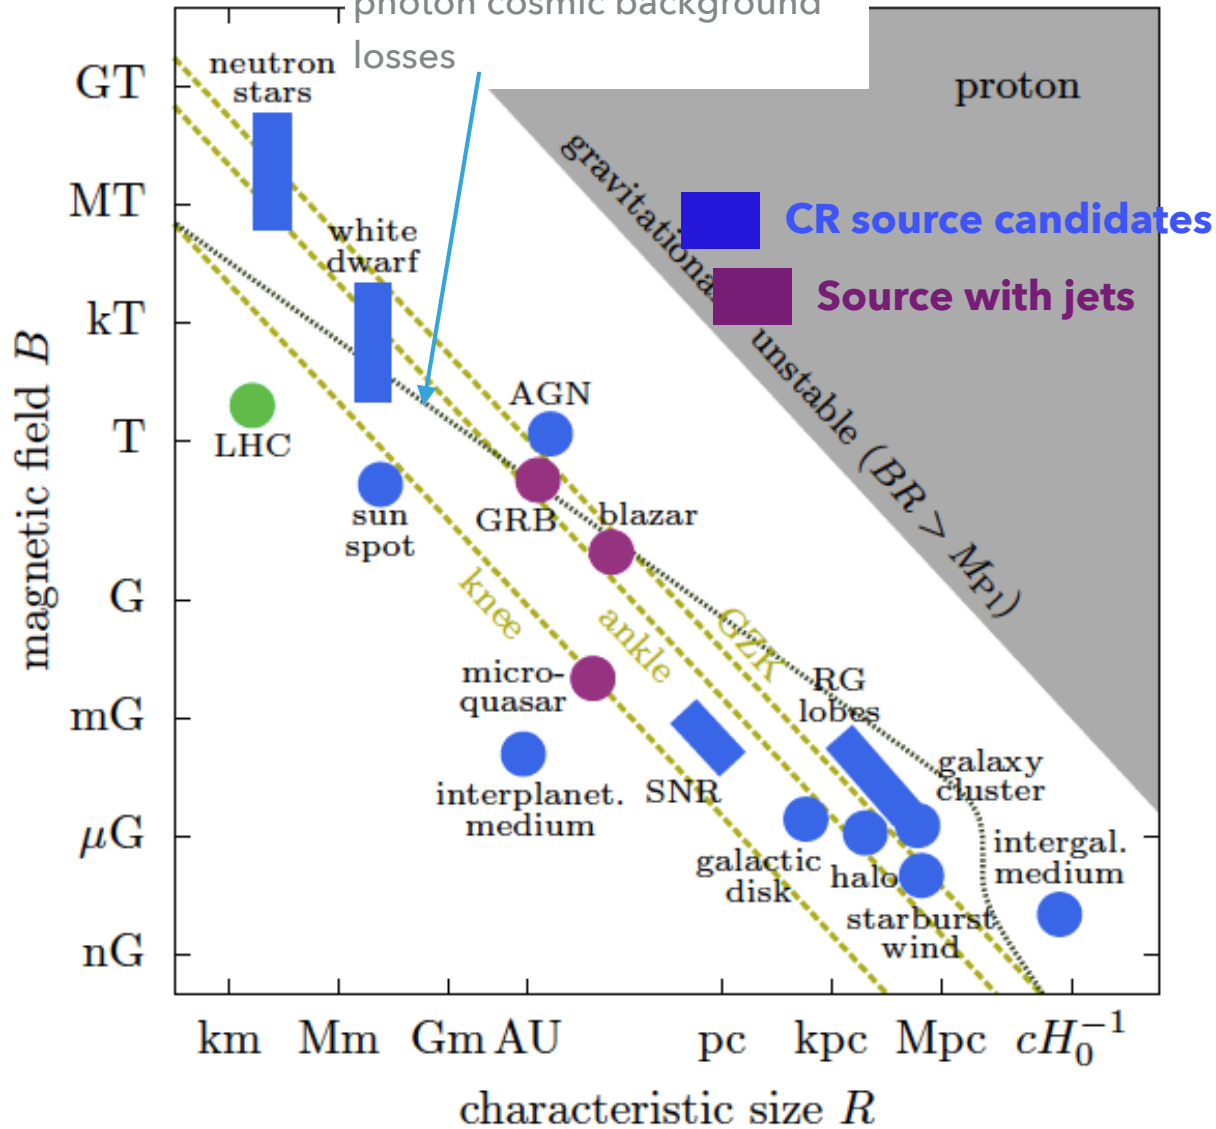

---

An LHC with the radius of the Mercury orbit could accelerate protons to  $10^{20}$  eV =  $10^7$  x LHC!

# MESSENGER ACCELERATION: THE HILLAS' PLOT

Upper limit from synchrotron and proton interaction on photon cosmic background losses

Lorentz force

$$F_L = qvB = m \frac{v^2}{R}$$

Imposing that the Larmor is equal to the accelerating region

$$R = R_{acc}$$

We find the maximum energy at which the charged relativistic particle with  $q = Ze$  can be accelerated

$$R_L = \frac{cp}{ZeB} \approx 100 \text{ pc} \frac{3\mu\text{G}}{B} \frac{E}{Z \times 10^{18} \text{ eV}}$$

$$E_{max} \simeq Z \left( \frac{B}{\mu\text{G}} \right) \left( \frac{R_{source}}{\text{kpc}} \right) \times 10^9 \text{ GeV}$$

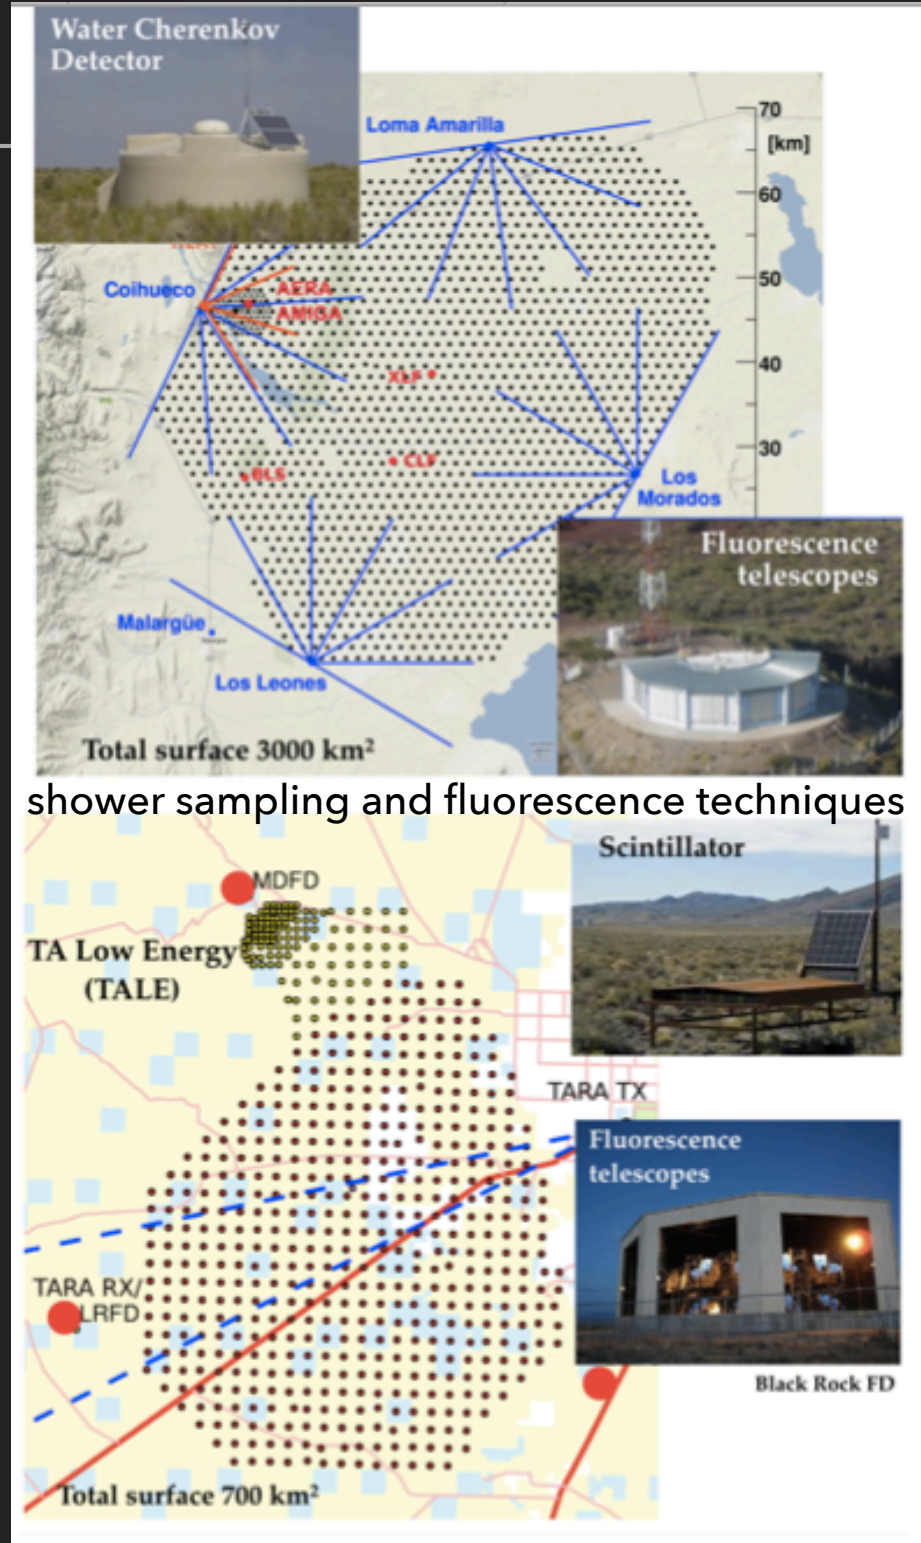

For jets with Lorentz factors  $\Gamma$ ,  $E_{max} \cong \Gamma ZBR$

# UHECR MESSENGERS

Can UHECR be cosmic messengers?

Yes ! But only in a tiny energy window between the minimum energy at which they are not deflected by B-fields and when they are not absorbed on cosmic radiation (GZK cutoff).

# MAGNETIC FIELD DEFLECTIONS OF UHECRS

If UHECR are not protons then astronomy with them will be not easy due to larger magnetic deflections.

$$mv^2 / r = pv / r = ZevB / c$$

$$r = pc / ZeB$$

$$r(cm) = \frac{1}{300} \frac{E(eV)}{ZB(G)}$$

$$(10^{12} eV) = 10^{15} cm = 3 \times 10^{-4} pc$$

$$r = (10^{15} eV) = 10^{18} cm = 3 \times 10^{-1} pc$$

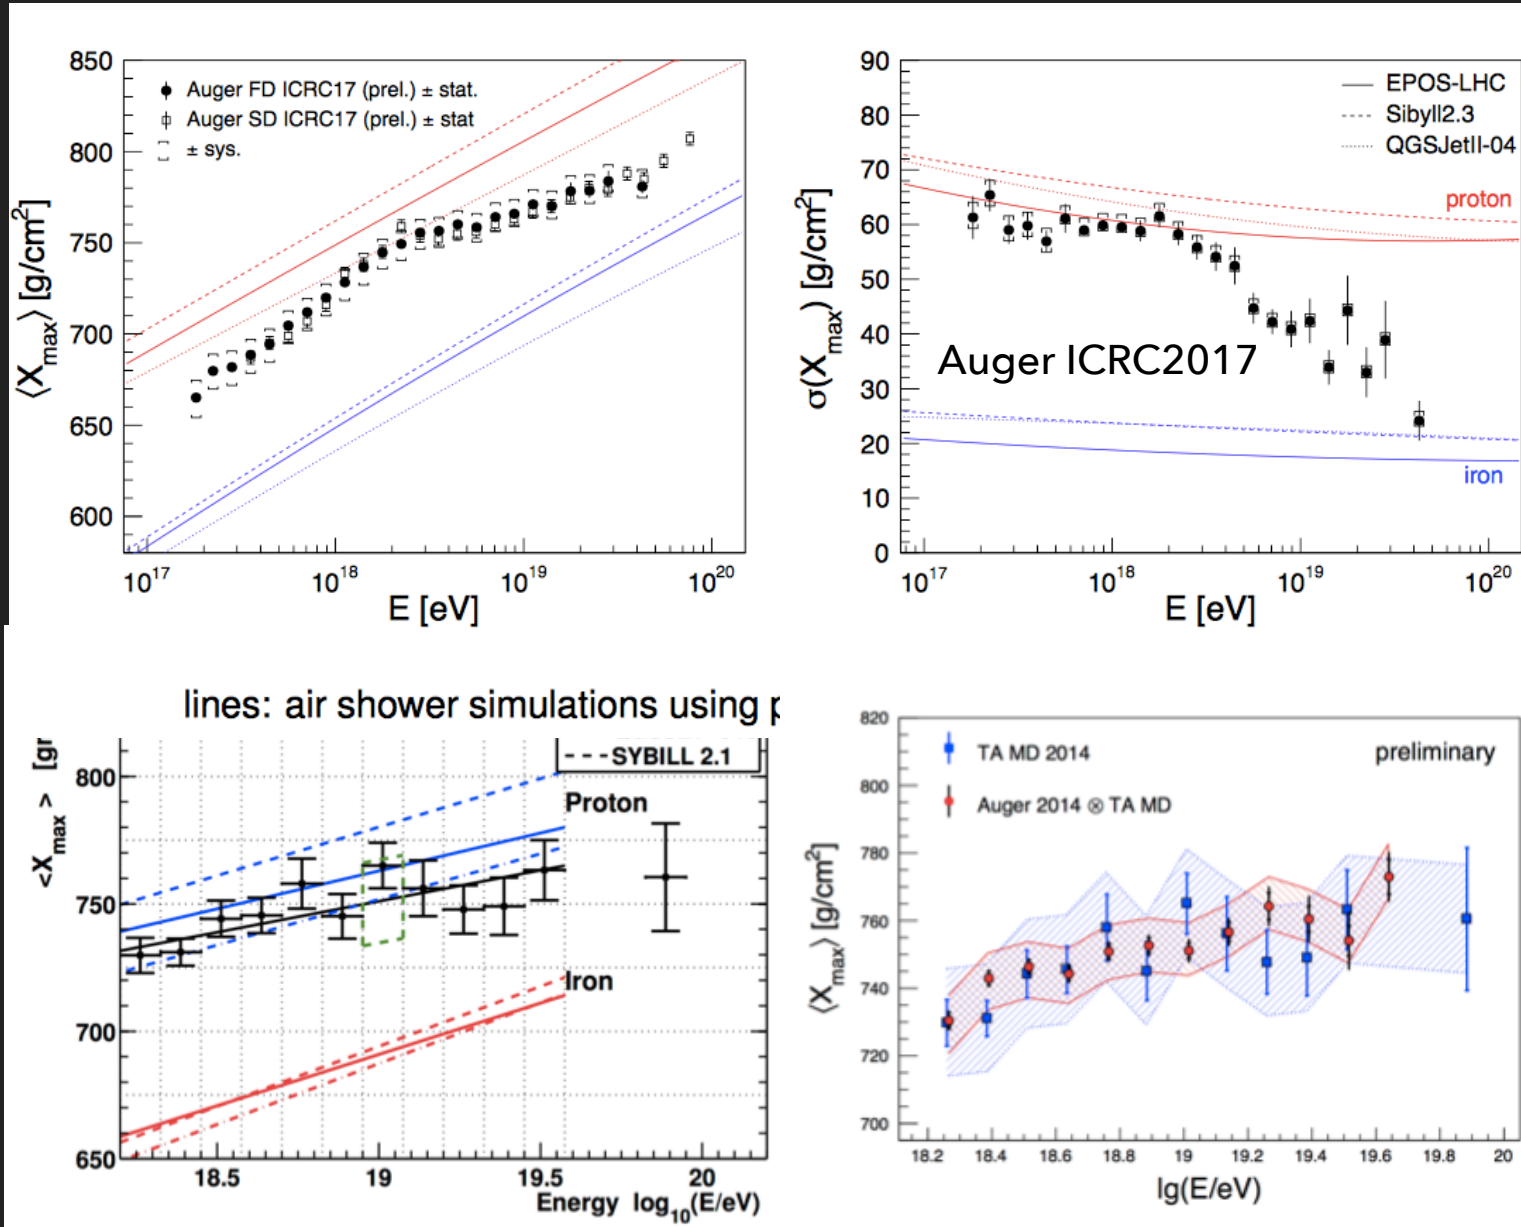

$$(10^{18} eV) = 10^{21} cm = 300 pc$$

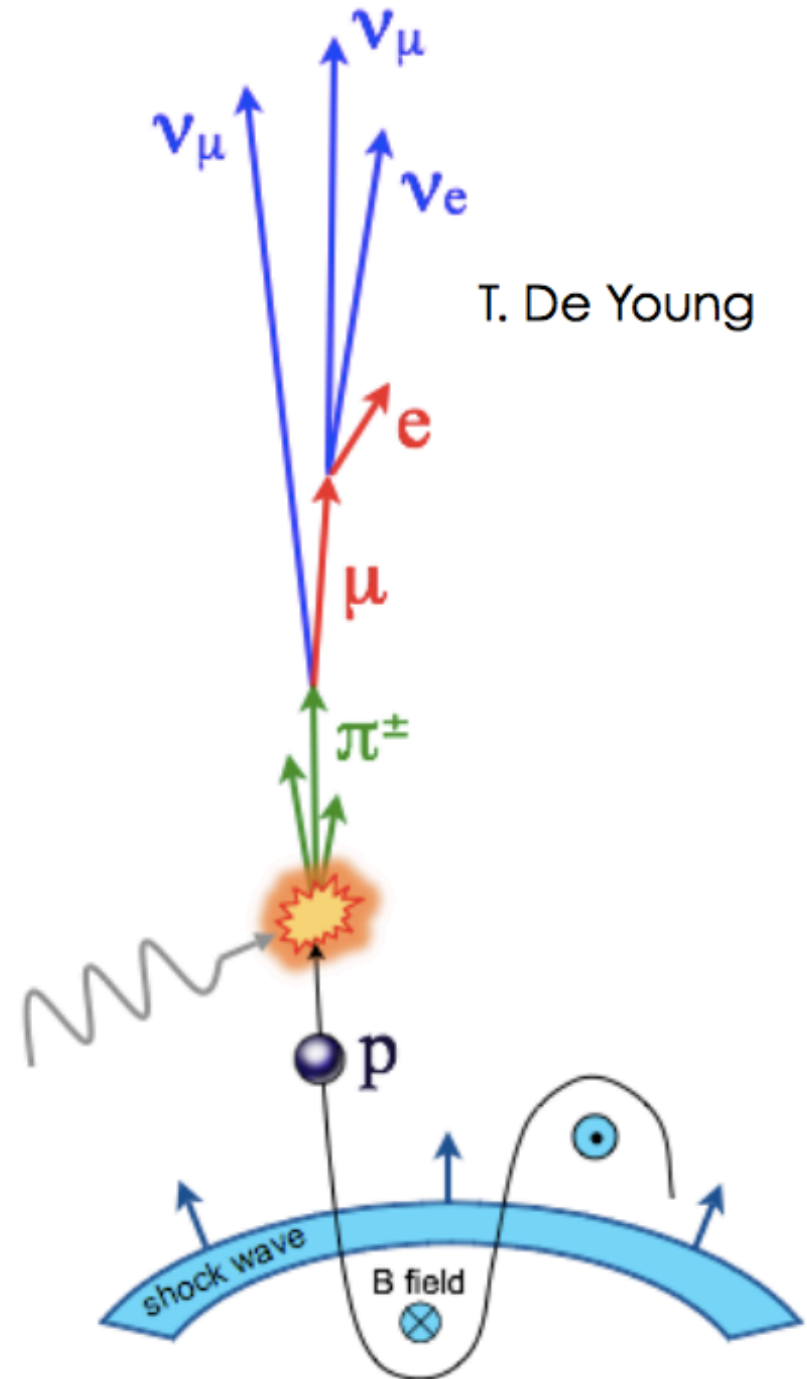

# THE UHECR COMPOSITION

$X_{\max}$  = depth in the atmosphere where showers maximum occurs. It is an indicator of the composition since Fe showers penetrate less in the atmosphere than proton once principally due to the smaller interaction length.

# THE GENERIC MESSENGER SOURCE: EARTH & HEAVEN

# THE GENERIC MESSENGER SOURCE : A COSMIC BEAM DUMP

**Hadronuclear (e.g. star burst galaxies and galaxy clusters)**

**Photohadronic (e.g. gamma-ray bursts, active galactic nuclei)**

Neutrino flavour ratio at source:

pion-muon decay

$$\nu_e : \nu_\mu : \nu_\tau \sim 1 : 2 : 0$$

Oscillations average out over cosmic baselines

$$\nu_e : \nu_\mu : \nu_\tau \sim 1 : 1 : 1$$

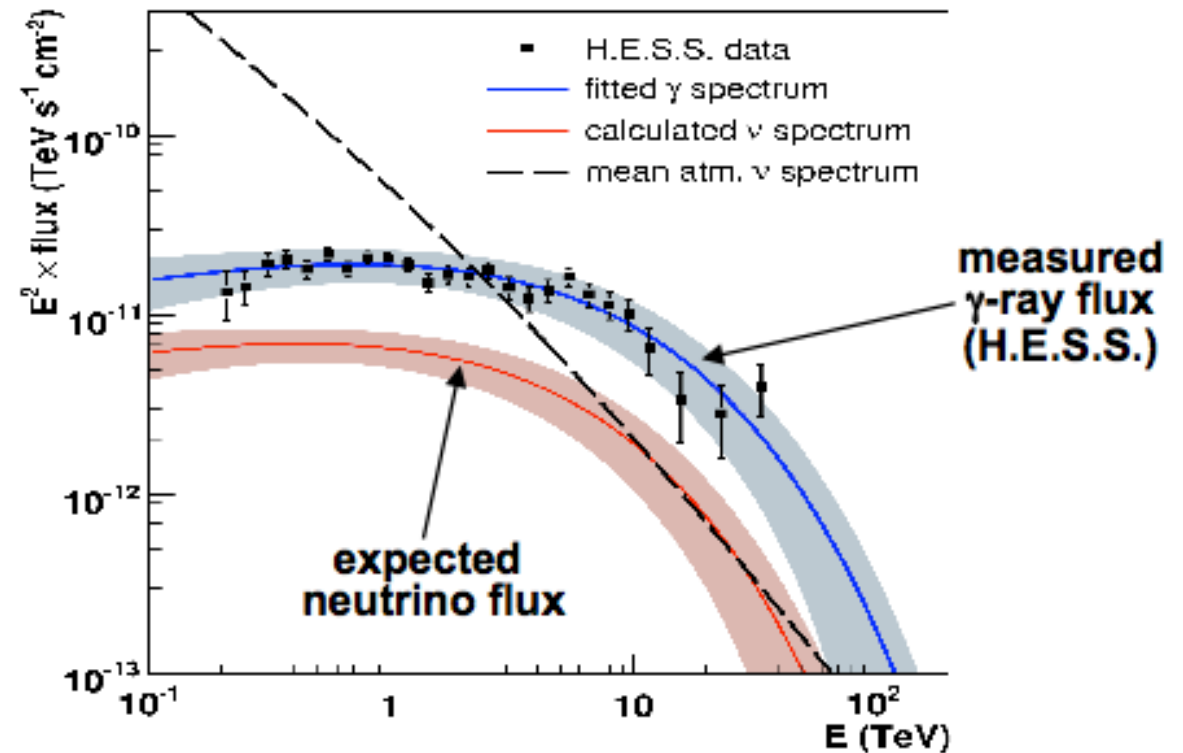

# NEUTRINO SPECTRA FROM COSMIC RAY AND GAMMA SPECTRA

Neglecting gamma-ray absorption and including standard neutrino oscillations

$$\frac{dN_\nu}{dE} = \frac{dN_\gamma}{dE} \text{ for } p - p$$

$$\frac{dN_\nu}{dE} = \frac{dN_\gamma}{dE} \text{ for } p - \gamma$$

$\gamma$

## “Shower”

For  $E=1$  TeV ( $E_C \approx 80$  MeV)

$$X_{\max} \approx X_0 \ln ( E/E_C ) / \ln 2$$

$$h_{\max} = h_0 \ln(X_A/X_{\max}) \rightarrow 5 \text{ km}$$

*UV-optical reflecting mirrors focussing flashes of Cherenkov light produced by air-showers onto ns-sensitive cameras.*

1.4°

Cherenkov radiation

~10 km

140 m

# IACT detection in detail

- the camera images the shower piece by piece on hit pixels with ns precision
- we can reconstruct where is the **source of gamma-rays** !
- With more than a telescope, **the precision on the position** of the source improves

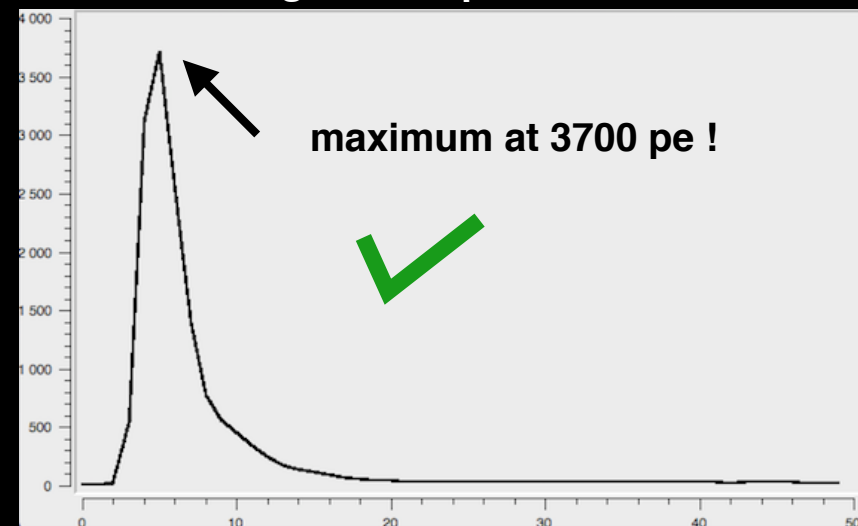

# A camera at night

- How we can have a clear signature from gamma-rays on top of the noise?
  - ➔ It is enough to set a threshold on the amplitude of signals

Signal of a pixel during a night with moon

Signal with photons

**Threshold:**  
**pe > 550**

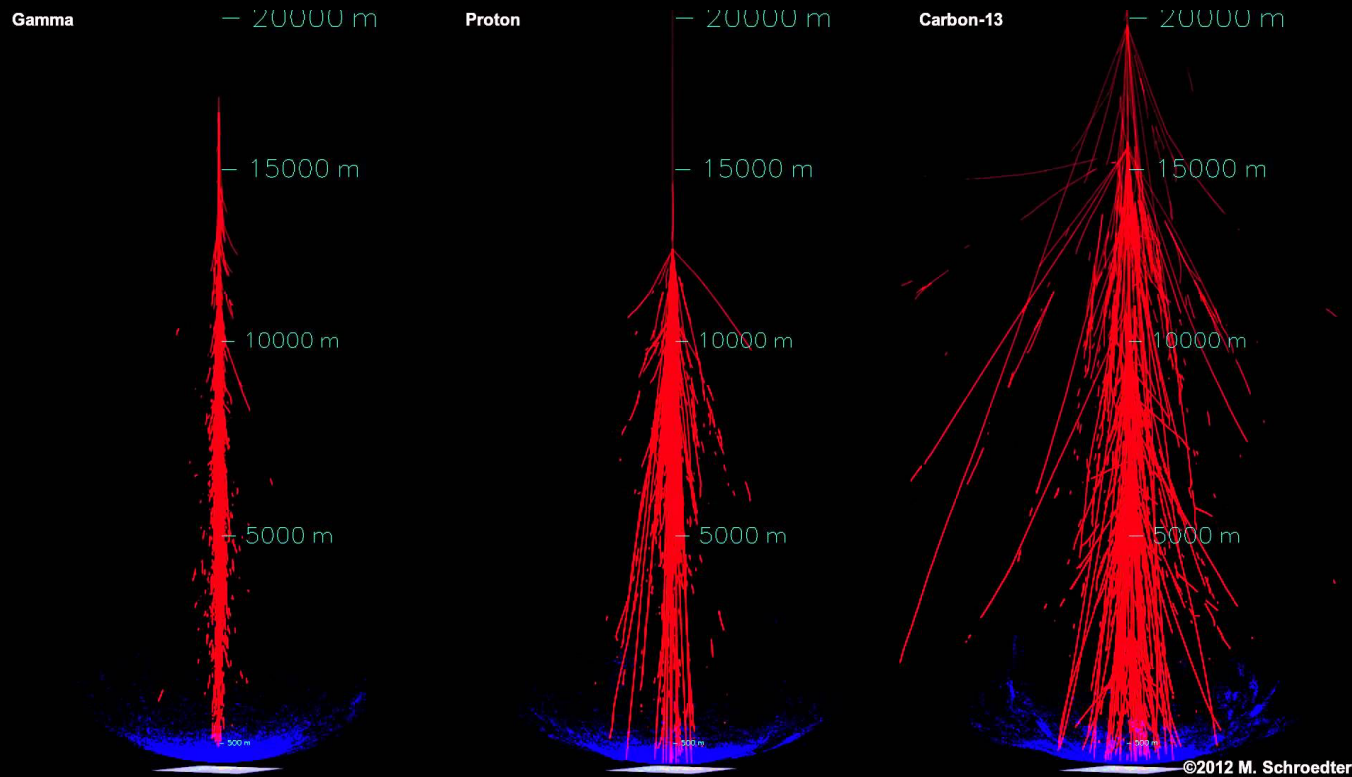

**The noise is totally reduced!**

# Can we identify gamma-rays?

→ It is not so simple....

- there are about  $10^5$  more cosmic ray hadronic showers,
- energy and inclination of showers affect them and when energy is low it is tough to have clear images
- the core of the shower (the Centre of Mass of the charge) can be close or far from the telescope

# The signature of a gamma-ray

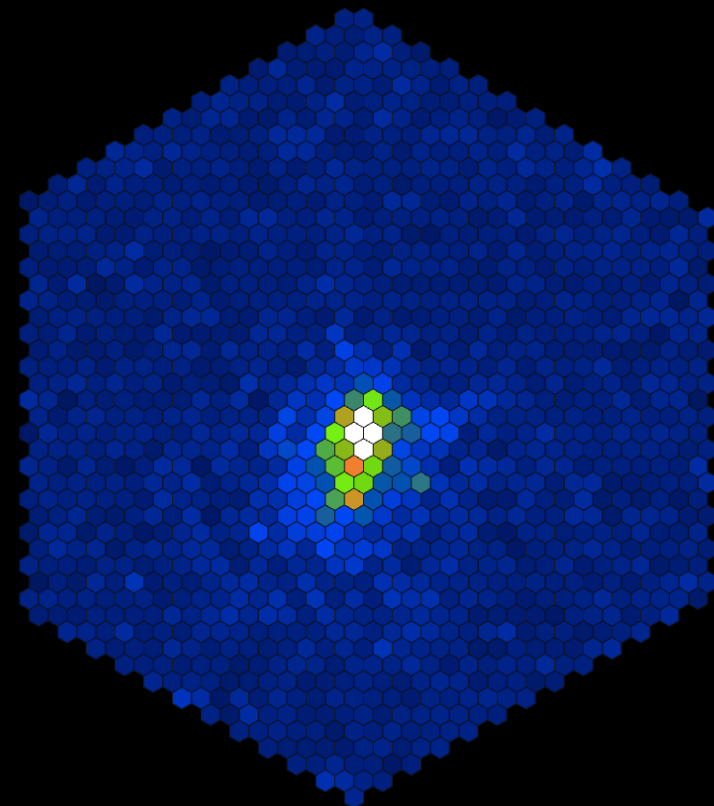

→ elongated shape

→ regular charge development

# The signature of an hadron

→ The development of the shower is sparse on the plane of the camera

- The shape is more round and sometimes with sparse charge on far away pixels
- not a preferential direction

# THE SPECTRAL EMISSION FROM A TYPICAL ACCELERATOR: CRAB

# THE 1<sup>ST</sup> ACCELERATION MECHANISM IN SN REMNANTS

- ▶ One of the features of the 1<sup>st</sup> order Fermi accelerator is to produce  $E^{-2}$  spectra maximum acceleration energy since the accelerator has finite lifetime  $T_A$  the

$$E \leq E_0(1 + \xi)^{T_A/T_{cycle}}$$

$T_{cycle}$ : time the particle takes to cross back and fourth the shock

- ▶ For a SN the shock is an efficient accelerator until the density of ejecta becomes comparable to the density of ISM in the Galaxy (order of 100-1000 yrs)  $\Rightarrow$   
 $E_{max} \sim 100 \text{ TeV} \times Z$

- ▶ This energy is about an order of magnitude lower than the knee of  $\sim 3 \text{ PeV} \times Z \dots$

PROBLEM!

- ▶ SN efficiency is age dependent

# NOT YET A SNR PEVATRON OBSERVED BY GAMMA-RAY EXPERIMENTS

**NO PEVATRON SNR (YET)**

# BEYOND DSA

Non-linear DSA (dynamical connection between CRs being accelerated and the background plasma) is in agreement with observed filaments due to synchrotron emission of electrons of dimensions of  $10^{-2}$  pc. They imply large B-fields of the order of 100  $\mu$ G

Chandra  
Cassiopeia A

Chandra  
SN 1006

$$\Delta x \approx \sqrt{D(E_{max})\tau_{loss}(E_{max})} \approx 0.04 B_{100}^{-3/2} \text{ pc}$$

$$B \approx 100 \mu\text{Gauss}$$

# SPECTRAL DISAGREEMENT WITH DSA

- ▶ Observed spectra are softer than what predicted by DSA ( $E^{-2}$ ) and on-linear DSA (concave shape)

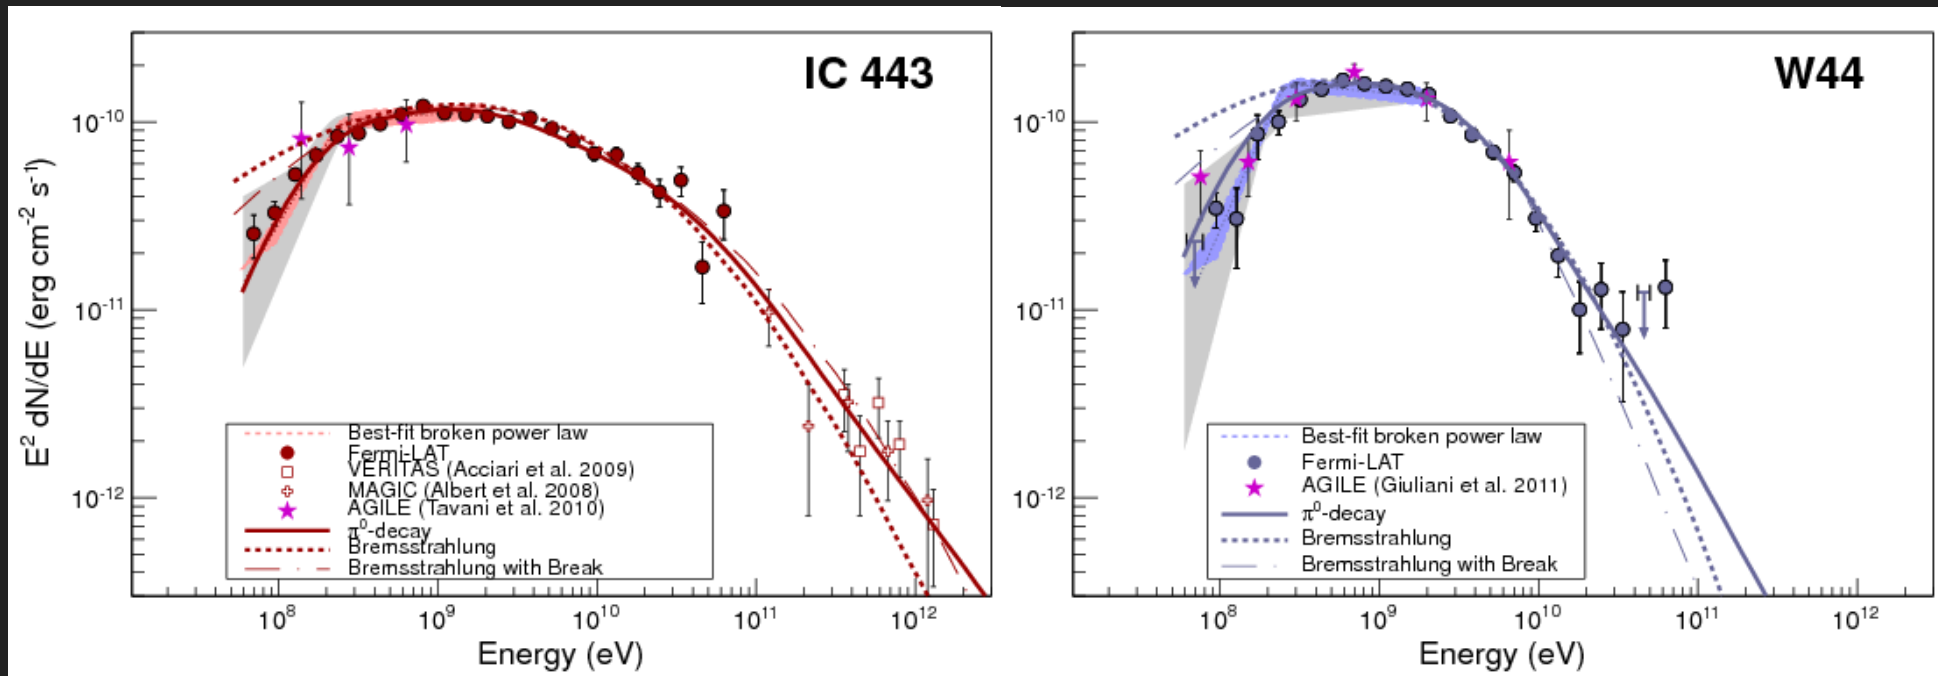

D. Caprioli et al. / *Astroparticle Physics* 33 (2010) 160–168

- ▶ Alternative source scenarios are possible: BH PeVatron in the Galactic Centre (H.E.S.S. arXiv:1603.07730) being more efficient accelerator or superbubbles

# THE TEV REGION

- ▶ In this region it is possible to identify CR acceleration through precise measurements of spectra of cosmic accelerators or the detection of astrophysical neutrinos from a source

Ackermann et al. (Fermi Collaboration), *Science*, 339, 807 (2013)

# SOME NEUTRINO ASTRONOMY HISTORICAL HINTS

1965: F. Reines detects neutrino with Cherenkov technique in South African mine

## Neutrino telescope concept birth

Ann.Rev.Nucl.Sci  
10 (1960) 63

### COSMIC RAY SHOWERS<sup>1</sup>

BY KENNETH GREISEN

Let us now consider the feasibility of detecting the neutrino flux. As a detector, we propose a large Cherenkov counter, about 15 m. in diameter, located in a mine far underground. The counter should be surrounded with photomultipliers to detect the events, and enclosed in a shell of scintillating material to distinguish neutrino events from those caused by  $\mu$  mesons. Such a detector would be rather expensive, but not as much as modern ac-

Fanciful though this proposal seems, we suspect that within the next decade, cosmic ray neutrino detection will become one of the tools of both physics and astronomy.
