

Higher order and skew magnets in PyECLOUD

Philipp Dijkstal

May 10, 2017

Thanks to G. Iadarola and G. Skripka

Higher order magnets at the LHC

Cell 13R2 occurred 111 times.

Cell 12R2 occurred 75 times.

Cell 25R2 occurred 58 times.

- ▶ in every cryogenic half-cell, sextupoles and sometimes octupoles are used
- ▶ previously, only drifts, dipoles and quadrupoles were supported

Higher order magnets

b) Dipole $I(\varphi) = I_0 \cos \varphi$

c) Quadrupole $I(\varphi) = I_0 \cos 2\varphi$

d) Sextupole $I(\varphi) = I_0 \cos 3\varphi$

$$B_y + iB_x = \sum_{n=0}^{\infty} \frac{1}{n!} (b_n + ib'_n) (x + iy)^n$$

- ▶ n: order of multipole
- ▶ here: dipoles are order 0
- ▶ $b_n = \left. \frac{\partial^n B_y}{\partial x^n} \right|_{x,y=0,0}$
- ▶ $b'_n = \left. \frac{\partial^n B_x}{\partial x^n} \right|_{x,y=0,0}$
- ▶ normal and skew PyECLLOUD input parameters

similar to J. Rossbach, P. Schmüser, *Basic course on accelerator optics*, 1993

Implementation

- ▶ calculation of B for one particle
- ▶ $B_y + iB_x = \sum_{n=0}^{\infty} \frac{1}{n!} (b_n + ib'_n) (x + iy)^n$
- ▶ $n!$ applied during initialization
- ▶ $(x + iy)^n$ is built incrementally
- ▶ *complex* C datatype turned out to be slow → explicit complex calculation for $(x + iy)^n$

Implementation

- ▶ calculation of B for one particle
- ▶ $B_y + iB_x = \sum_{n=0}^{\infty} \frac{1}{n!} (b_n + ib'_n) (x + iy)^n$
- ▶ $n!$ applied during initialization
- ▶ $(x + iy)^n$ is built incrementally
- ▶ *complex C* datatype turned out to be slow → explicit complex calculation for $(x + iy)^n$

```

rexy = 1.;
imxy = 0.;
By_n = B_field[0]; // Dipole covered here
Bx_n = B_skew[0];
for (order = 1; order < N_multipoles; order++){
    /* rexy, imxy correspond to real,
       imaginary part of (x+iy)^n */
    rexy_0 = rexy;
    rexy = rexy_0*xn1p - imxy*yn1p;
    imxy = imxy*xn1p + rexy_0*yn1p;
    /*
    * Bx + iBy = sum[ (k + ik')(x + iy)^n ]
    * where k, k' are the strengths and skew strengths of the magnet
    */
    By_n += (B_field[order]*rexy - B_skew[order]*imxy);
    Bx_n += (B_field[order]*imxy + B_skew[order]*rexy);
}

```

Field maps

- ▶ test boris tracker
- ▶ *test_multipole.py* in PyECLoud code
- ▶ equally spaced particles with $\mathbf{v} = v_z$
- ▶ $\mathbf{F} = m \cdot \mathbf{a} = e \cdot \mathbf{v} \times \mathbf{B}$
- ▶ solve for \mathbf{B} after one time step

Field maps after rotation

$$B_{\text{multip}}^{(n)}(\varphi) = B_{\text{multip}}^{(n)}(0) \cdot \cos((n+1)\varphi)$$

$$B_{\text{skew}}^{(n)}(\varphi) = B_{\text{multip}}^{(n)}(0) \cdot \sin((n+1)\varphi)$$

- ▶ angle 45°
- ▶ consistent field maps

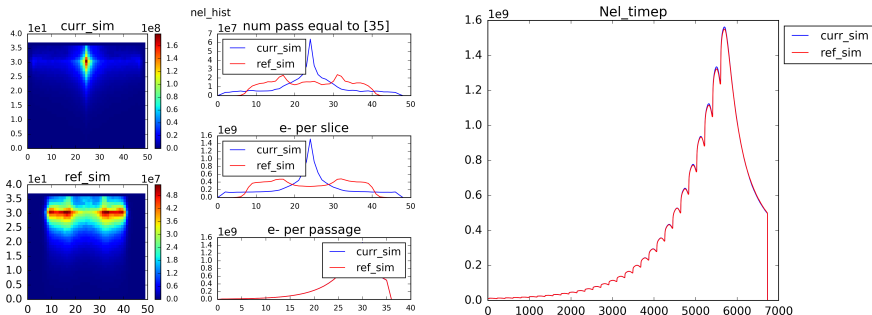

Field strength along axis

- ▶ $B_y^{(n)}(x = 1 \text{ m}) = 1$
- ▶ no skew component
- ▶ matches expected behavior

Comparison of normal vs skew quad in circular chamber

- ▶ reference simulation: circular chamber with original field computation
- ▶ current simulation: circular chamber with 45° skew quad and new field computation
- ▶ test case in PyECLoud code
- ▶ symmetric case, identical outcome expected
- ▶ heat loads agree to 0.7%

Scan of substeps in time

Sensitivity of multipoles on substeps

- ▶ Do the simulations converge?
- ▶ Substeps of MP motion for $Dt = 10^{-11}$ s
- ▶ 5 is a good choice

Movies

- ▶ 2 gif files on indico
- ▶ electron densities in octupole and sextupole
- ▶ one bunch passage

Usage

- ▶ from PyECLoud documentation

B_multip	Magnetic momenta. For example: to simulate a dipole with $B=8.3$ T $B_multip = [8.3]$; to simulate a quadrupole with gradient 12 T/m set $B_multip = [0., 12.]$.
B_skew	The skew parameters can be included through B_skew . For a skew quadrupole, set B_multip to $[0., 0.]$ and B_skew to $[0., 12.]$.

- ▶ example of sextupole:

$B_multip = [0, 0, 6.31 e4]$

$B_skew = None$

Usage - conversion from normalized field strengths

- ▶ convert k_i (e.g. from MADX) to B_{multip}
- ▶ same procedure for k_{skew} to B_{skew}
- ▶ k : magnetic field derivative on x axis, normalized by beam rigidity $B\rho$
- ▶ for order n :

$$\underbrace{k_n}_{\text{in MADX files}} = \frac{1}{(B\rho)} \frac{\partial^n B_y}{\partial x^n}$$

$$\underbrace{\frac{\partial^n B_y}{\partial x^n}}_{\text{PyECLLOUD input}} = k_n(B\rho)$$

- ▶ from MADX documentation:

K2 The normal sextupole coefficient $K_2 = \frac{1}{B\rho}(\partial^2 B_y/\partial x^2)$.
(default: 0 m⁻³).

K2S The skew sextupole coefficient $K_{2s} = \frac{1}{B\rho}(\partial^2 B_x/\partial x^2)$
where (x,y) is now a coordinate system rotated by -30° around s with respect to the normal one. (default: 0 m⁻³). A positive skew sextupole strength implies *defocussing* (!) irrespective of the charge of the particles, in the (x,s) plane rotated by 30° around s (particles in this plane have $x > 0$, $y > 0$).

Usage - conversion from tilting angle

- ▶ tilting angle φ

$$B_{\text{multip}}(\varphi) = B_{\text{multip}}(0) \cdot \cos((n+1)\varphi)$$

$$B_{\text{skew}}(\varphi) = B_{\text{multip}}(0) \cdot \sin((n+1)\varphi)$$

Higher order and corrector magnets at LHC

- ▶ obtain k_2 (sextupoles), k_3 (octupoles) from MADX files or LHC control system

Magnet	Identifier	Variable	Origin	Value
Kicker-V	MCBV	$B_{\text{skew}}(7 \text{ TeV})$	MADX	2.5 T
Kicker-H	MCBH	$B(7 \text{ TeV})$	MADX	2.93 T
Sextupole	MS	k_2	LHC data base	-0.12
Sextupole	MS2	k_2	LHC data base	0.07
Octupole	MO	k_3	LHC data base	1 6

First results - heat load against SEY

- ▶ initial seeding
- ▶ 6500 GeV
- ▶ also show drifts, dipoles and quadrupoles

Summary and future studies

- ▶ done: higher order, compound and skew magnets part of PyECLLOUD
- ▶ validation and documentation complete, version 6.2 to be released today
- ▶ different interface in version 6.1, so please use 6.2! (no difference for dipoles and quadrupoles)
- ▶ up next: photoemission seeding
- ▶ systematic modelling of cells
 - ↔ what are the expected heat loads including multipoles and photoemission seeding?
