

# Mitigation of Direct APD signals in the CMS Barrel Electromagnetic Calorimeter

Catherine Schiber

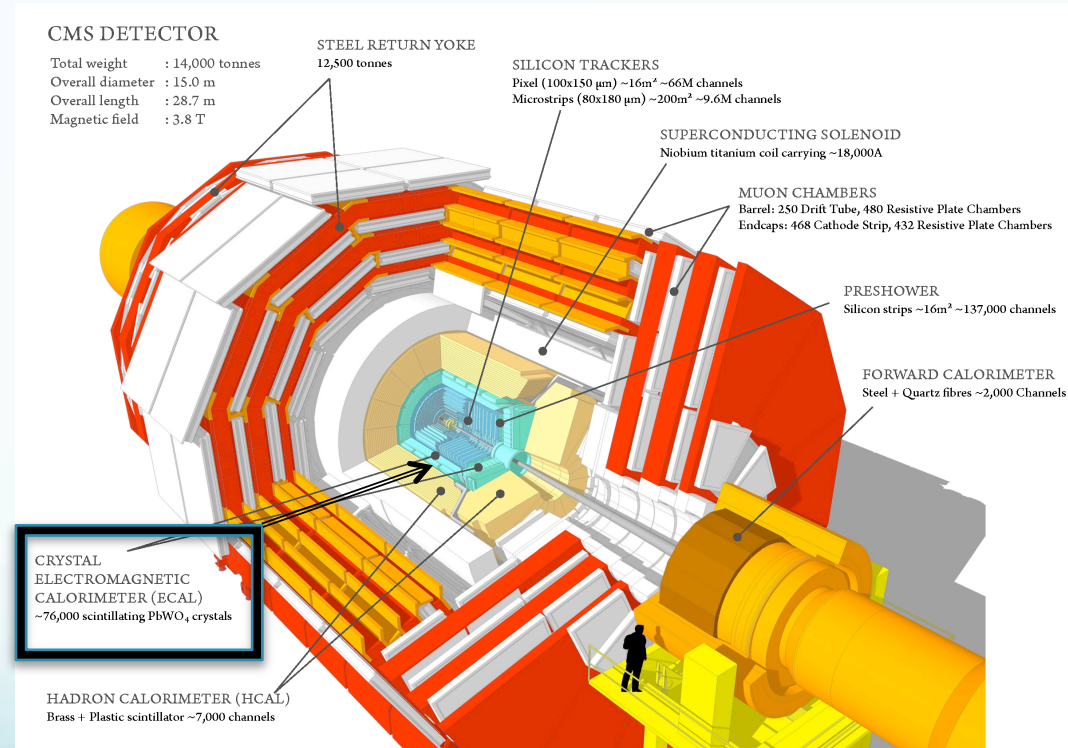

For the CMS Collaboration

CALOR 2018, Eugene, 21-25 May

# Outline

- Collider & Detector
- What are direct APD signals
- Mitigation of APD signals
  - Offline and online rejection algorithms
- Optimization
  - 2017 Optimization Study
  - Effect of pedestals
  - Phase II

# CMS ECAL Geometry

- Consists of 75,848 lead tungstate ( $\text{PbWO}_4$ ) crystals
- Organized into 3 sections
  - Barrel (EB)
    - 36 supermodules of 1700 crystals each
    - Total of 61200 crystals
    - Covers  $|\eta| < 1.48$
  - Endcap (EE)
    - 4 half-disk Dees of 3662 crystals
    - Total of 14648 crystals
    - Covers  $1.48 < |\eta| < 3.0$
  - Preshower (ES)
    - Two Lead/Si planes
    - Total of 137,216 Si strips ( $1.9 \times 61 \text{ mm}^2$ )
    - Covers  $1.65 < |\eta| < 2.6$

# ECAL Crystals

- Compact:
  - Dense
  - Short radiation length (0.89 cm)
  - Small Moliere radius (2.2 cm)
- Scintillation time  $\sim 25$  ns
- Difficulties
  - Low light production
  - Temperature dependent light production
  - Suffer some radiation damage
- Photodiodes glued to the ends

# The Photodetectors

- Vacuum Phototriodes (VPTs) in the ECAL Endcaps
- Avalanche Photodiodes (APDs) in the ECAL Barrel
  - Hamamatsu type S8148 reverse structure avalanche photodiodes
  - Each has an active area of  $5 \times 5 \text{ mm}^2$
  - A pair is mounted in a capsule which is glued to the crystal
  - Operated at gain 50 and read out in parallel
  - Internal construction includes a  $5 \mu\text{m}$  thick 'high gain' silicon layer

# ECAL & CMS Trigger

- Trigger Tower (TT)
  - 5×5 array of crystals
- Trigger Primitives (TPs)
  - TPs are transverse energy sums formed on-detector from TTs
  - TPs are formed on-detector.
  - Used to form electron/photon, jet, tau candidates, and energy sums
  - Sent to Level-1 (L1) trigger at 40 MHz
    - Total L1 trigger bandwidth is 100 kHz

**TP path summary**

# Direct APD Signals

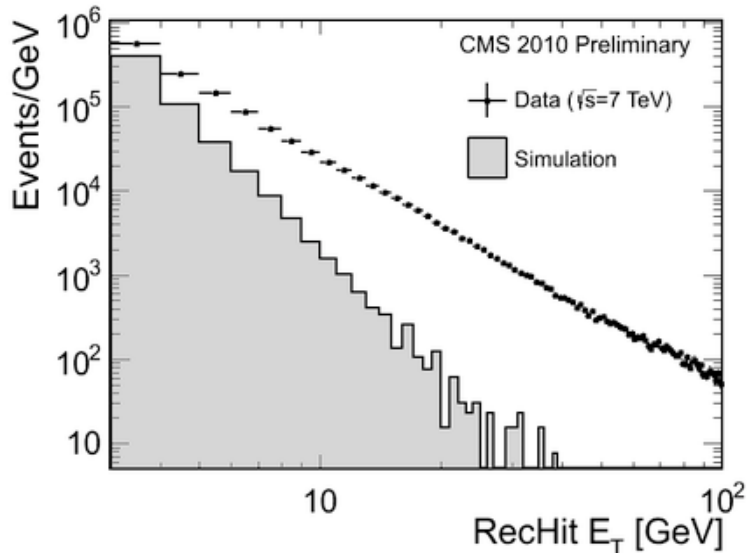

- Caused by particles striking the APDs and occasionally interacting and causing large anomalous signals through direct ionization of the silicon
- Also called ‘spikes’
- Spike rate proportional to collision rate.
- Can be detected online or offline
- Algorithms designed to detect them are also known as ‘Spike Killer’ (SK)
- Trigger rates depend on performance of online spike rejection algorithm

# Spike Energy Spectrum

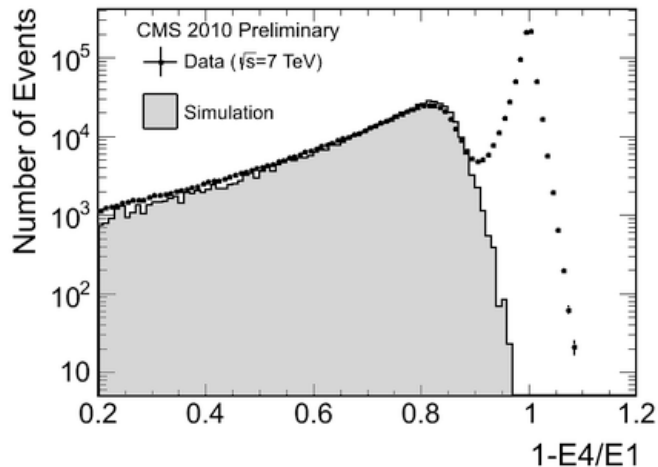

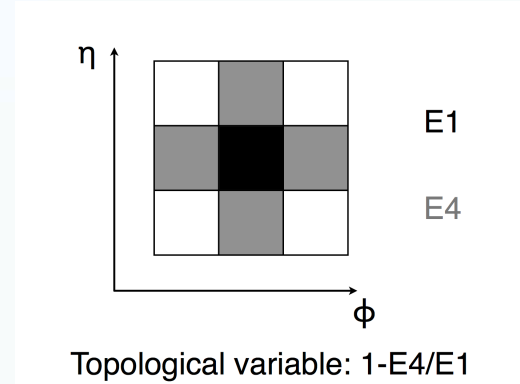

- ECAL spikes often satisfy the conditions for triggering electrons and photons in CMS
- Spike contamination grows with energy
- To maintain low unprescaled electron/photon triggers, spikes must be identified and removed

**Distribution of the transverse energy of the highest energy signals for data and MC**  
Both distributions are normalized to the same number of events with  $E_T > 3$  GeV and  $1 - E_4/E_1 < 0.9$

# Offline Rejection: Swiss Cross

- Spikes deposit energy in a single channel
- Swiss Cross Variable ( $1 - E4/E1$ )
  - EM showers have  $\sim 80\%$  of their energy in the central crystal.
  - A selection of 0.95 is applied

The distribution of the “Swiss-cross” variable ( $1 - E4/E1$ ) for data and Monte Carlo minimum bias events

# Offline Rejection: Timing

- Spikes lack the scintillation response time
- Appear early when the pulse is fitted to extract timing
- Selection of  $\pm 3\text{ns}$  on signal timing is applied (timing resolution  $< 1\text{ns}$  for electromagnetic signals with energy  $> 1\text{ GeV}$ )

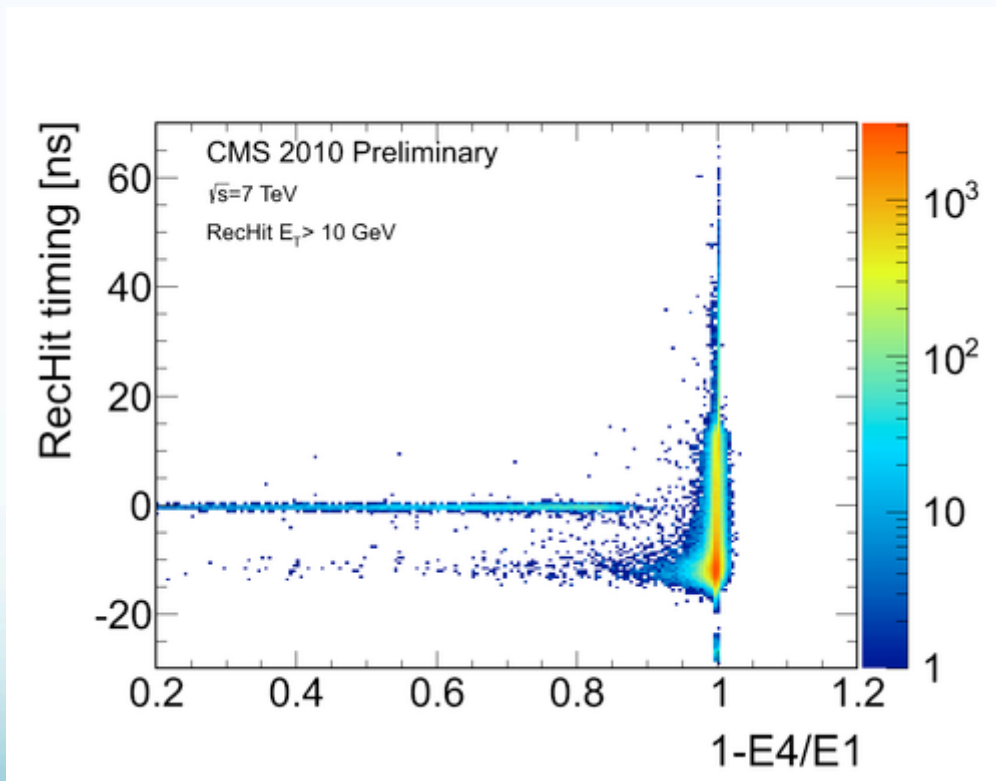

**Average ECAL Pulse shapes for spike and EM signals, measured on data**

**Distribution of the reconstructed time of the highest energy signals for data and MC**

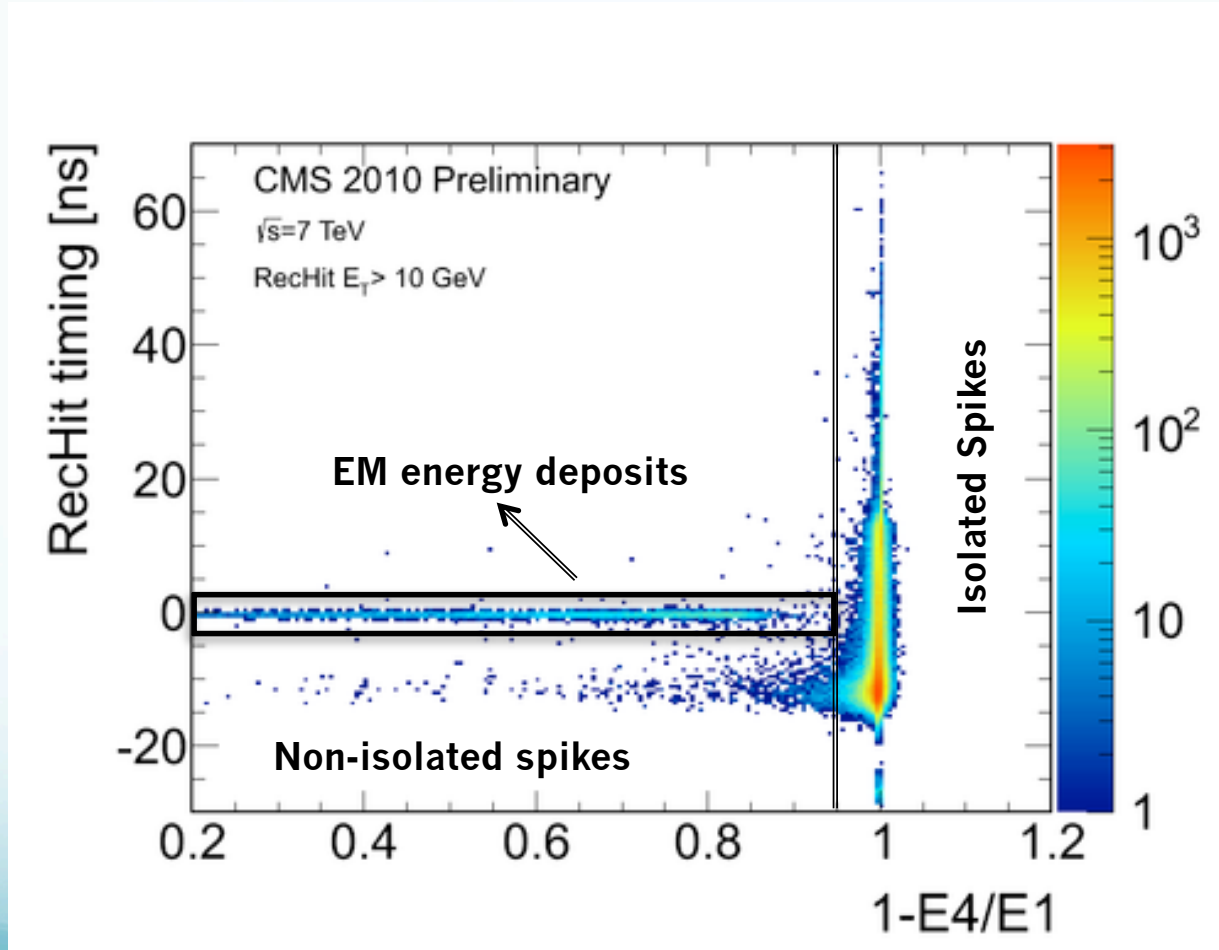

# Efficiencies of Offline Rejection

- Signal Timing vs Swiss-cross
- Together were measured to reject  $>99.9\%$  of spikes with  $E_T > 10$  GeV.

2D distribution of signal timing vs Swiss-cross variable for CMS Data

# Efficiencies of Offline Rejection

2D distribution of signal timing vs Swiss-cross variable for CMS Data

# Online Rejection

- Strip Fine-Grained Veto Bit (sFGVB)
- If the sFGVB is 0 and the trigger tower energy is greater than the threshold, the energy deposit is considered spike-like.
- Two thresholds, single crystal for the sFGVB and the tower  $E_T$

## EM shower

sum over 5x1 strip

number of hits above threshold: 1 3 1 0 0  
strip bit: 0 1 0 0 0

sFGVB result: **1** (shower-like)

## Spike

number of hits above threshold: 0 1 0 0 0  
strip bit: 0 0 0 0 0

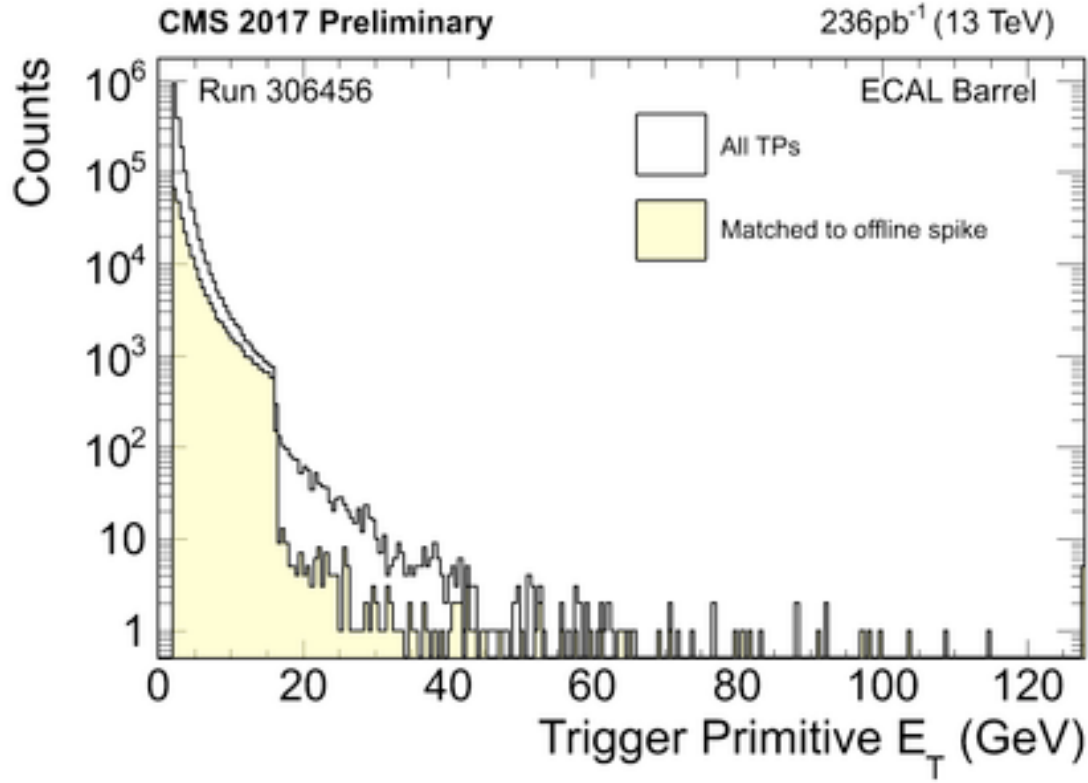

sFGVB result: **0** (spike-like)

■ crystal above threshold  
□ crystal below threshold

# 2017 Performance Check

- Most recent retuning of the sFGVB done in 2016.
- In 2017, used pedestals from the end of 2016
- Plots shown from a high pileup (PU) run:  $45 < \text{PU} < 55$

# Trigger Primitive (TP) $E_T$ Spectrum

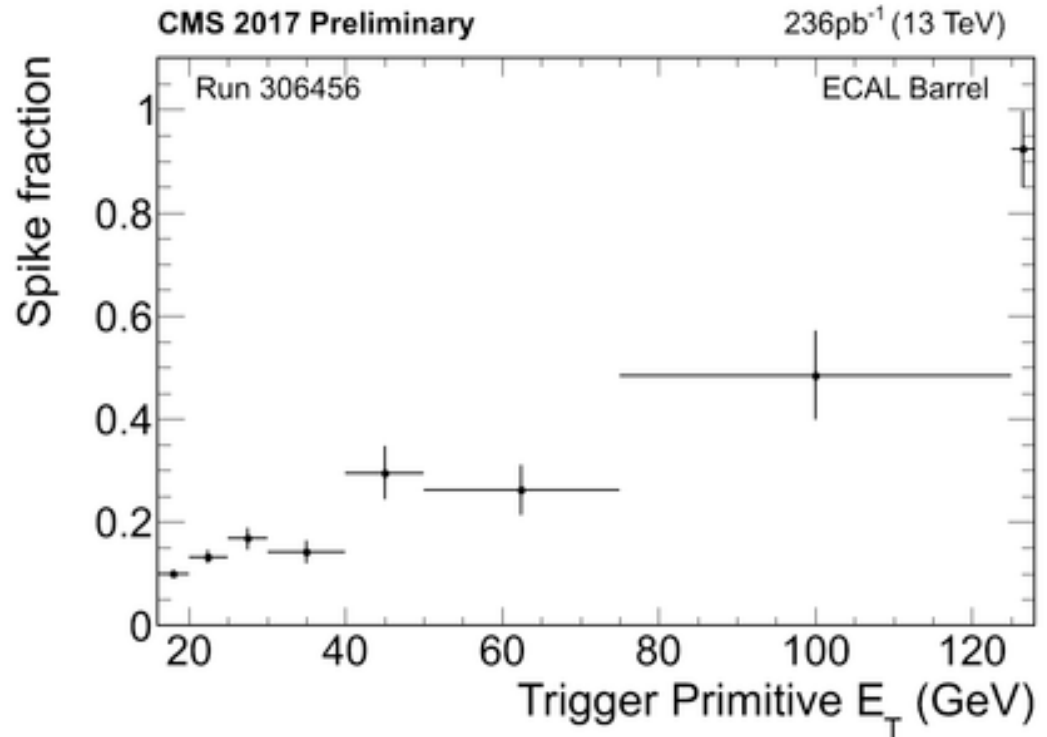

**Transverse energy distribution**  
**Black: TP spectrum**  
**Yellow: Residual spikes, matched offline using Swiss-cross and timing**  
**Discontinuity at 16 GeV due to online spike rejection**

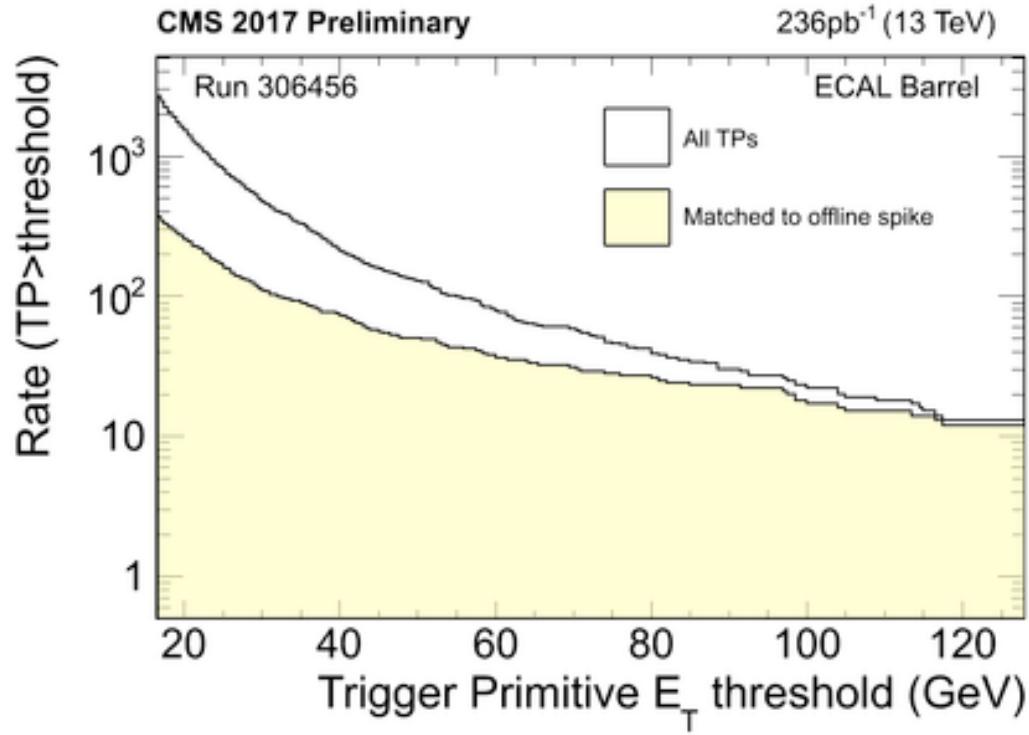

# Residual Spike Contamination per $E_T$ bin

**Residual spike contamination  
in the TPs as a function of  
transverse energy**  
Ratio of the two distributions  
(yellow and black) of the  
previous slide  
**Shows spike contamination  
grows with  $E_T$ , the last point is  
the saturated TPs**

# Integral TP Spectra

**Integral of the TP transverse energy spectrum as a function of transverse energy**  
TPs in black, residual spikes in yellow  
**Another way of showing spike contamination grows with  $E_T$**

# Misidentified Spike Fraction

**Fraction of TPs, above a given  $E_T$  threshold, due to spikes**  
Ratio of the two distributions of the plot on the previous slide

| $E_T$ Threshold | Spike Fraction |
|-----------------|----------------|
| 20 GeV          | 17%            |
| 30 GeV          | 24%            |
| 40 GeV          | 35%            |
| 50 GeV          | 39%            |

# Effect of incorrect pedestals

— true pedestal

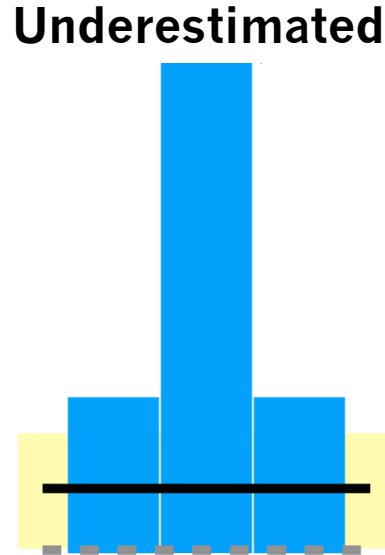

- - - applied pedestal

■ sFGVB threshold

Applied pedestal =  
real pedestal

Nominal behaviour

Applied pedestal <  
real pedestal

Signal less isolated

Spike rejection ↓  
Electron efficiency ↑ =

Applied pedestal >  
real pedestal

Signal more isolated

Spike rejection ↑ =  
Electron efficiency ↓ =

# Pedestal Drifts

**EB pedestal mean history in 2017**  
Monotonic drift upward + in-fill effects

# Spike Contamination with Updated Pedestals

## Fraction of TPs above a given $E_T$ due to spikes

2016 pedestals from Run 296917,  
2017 pedestals from Run 305848

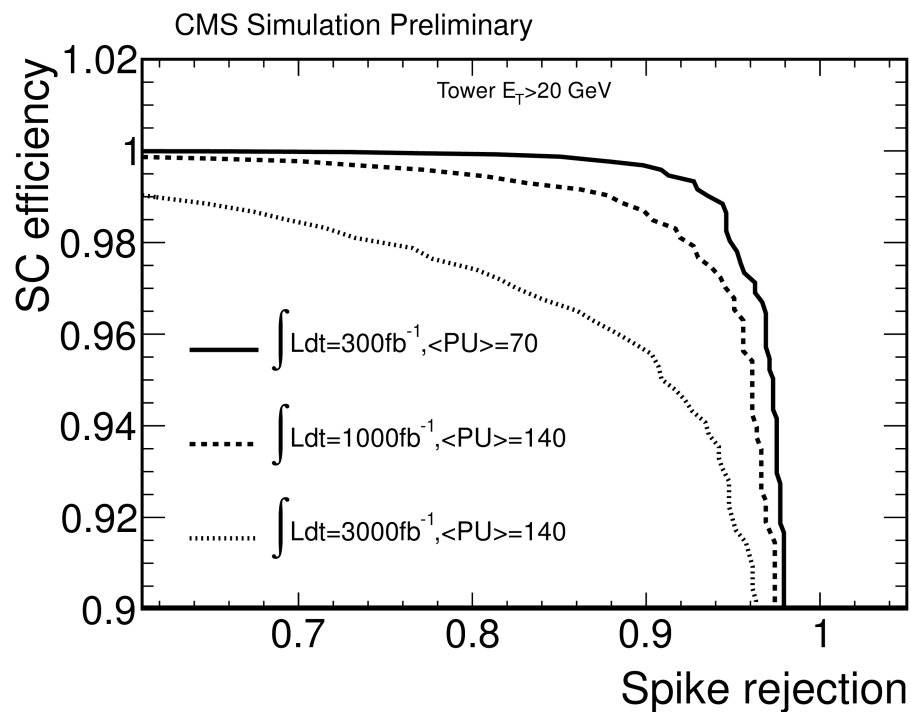

| $E_T$ threshold | Old pedestals | New pedestals |
|-----------------|---------------|---------------|
| 20 GeV          | 17%           | 14%           |
| 30 GeV          | 24%           | 19%           |
| 40 GeV          | 35%           | 29%           |
| 50 GeV          | 39%           | 33%           |

# L1 efficiency

**Efficiency of the Level-1 electron/photon (EG) trigger as a function of the offline electron supercluster transverse energy**  
**Uses a tag-and-probe method with  $|\eta| < 2.5$  (EB+EE)**  
**Plotted for L1 EG candidates with  $E_T > 30$  GeV and  $E_T > 40$  GeV**  
**Shows excellent performance of L1 Spike Killer during 2017**  
**Verified signal efficiency is unaffected by pedestal update**

# Phase II: Online SK Performance

**Predicted efficiency of online SK algorithm vs. signal acceptance (EM showers Z to ee events) for a range of detector aging and event pileup conditions**

**Only towers with  $E_T > 20$  GeV are considered**

**Up to end of Phase I ( $300fb^{-1}$ ) current SK algorithms perform well**

**Performance degraded in Run II due to larger pileup and APD noise**

**Upgrade required for Phase II**

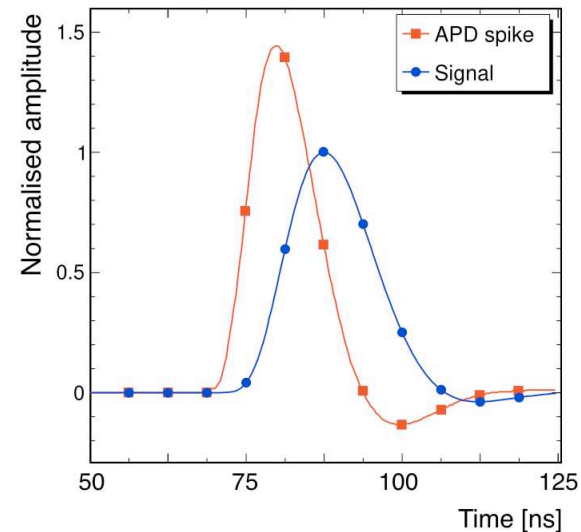

# Phase II: Offline SK Performance

- ECAL Barrel Phase II upgrade will replace on-detector and off-detector electronics
- Will improve spike rejection in the L1 trigger due to shorter pulse shaping in the on-detector electronics

## Current

## Upgrade

# Summary

- Large isolated signals ('spikes') have been observed in the CMS ECAL Barrel in pp and HI collisions at the LHC
- The rate of spikes is proportional to the minimum bias collision rate
- The online and offline rejection algorithms developed for spikes continue to perform well
- The algorithms have been retuned for the higher LHC luminosities of Run II
- Further study and optimization will take place as beam conditions and detector noise levels evolve

# Backup

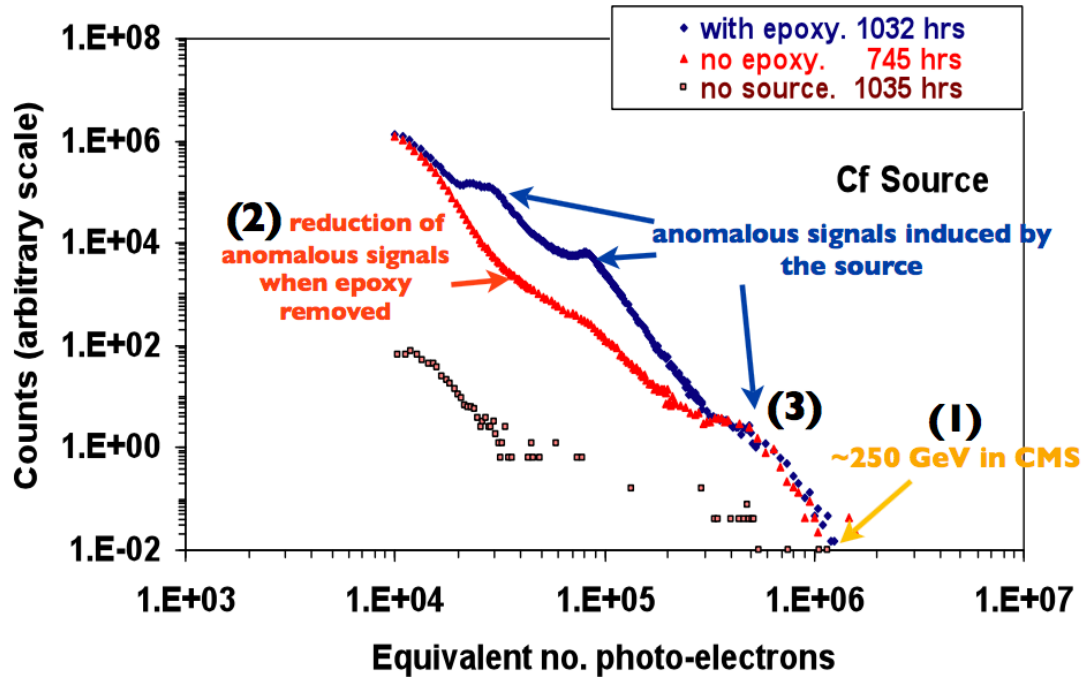

# APD Properties Summary

## At Gain 50 and 18 °C

|   |                    |
|---|--------------------|
| Sensitive area  | 5×5mm <sup>2</sup> |
| Operating voltage                                       | 340–430 V          |
| Breakdown voltage - operating voltage                   | 45 ± 5 V           |
| Quantum efficiency (430 nm)                             | 75 ± 2%            |
| Capacitance   | 80 ± 2pF           |
| Excess noise factor                                     | 2.1 ± 0.2          |
| Effective thickness                                     | 6 ± 0.5 μm         |
| Series resistance                                       | < 10 Ω             |
| Voltage sensitivity of the gain (1/M • dM/dV)           | 3.1 ± 0.1%/V       |
| Temperature sensitivity of the gain (1/M • dM/dT)       | -2.4 ± 0.2 %/°C    |
| Rise time   | < 2 ns             |
| Dark current  | < 50 nA            |
| Typical dark current                                    | 3 nA               |
| Dark current after 2×10 <sup>13</sup> n/cm <sup>2</sup> | 5 μA               |

# Laboratory Tests

**APD spectrum with/without  $^{252}\text{Cf}$  source.**  
for the data indicated by the red points: the protective epoxy layer is removed

- (1) Neutrons can induce high energy signals in the APDs with equivalent energies up to several hundreds of GeV in CMS
- (2) np interactions in the protective epoxy later, specifically in the hydrogen component, are an important component of the anomalous APD signals
- (3) At higher energies, signals due to direct ionization of the silicon are observed

# Monte Carlo Spike Studies

- A detailed model of the APD structure has been implemented (using Geant 4) in the CMS Monte Carlo simulation to further understand the origin of spikes and their rates in CMS

## APD Monte Carlo: location of spike progenitors
