

# R&D studies on eco-friendly gas mixtures for the ALICE Muon Identifier

### **Antonio Bianchi**

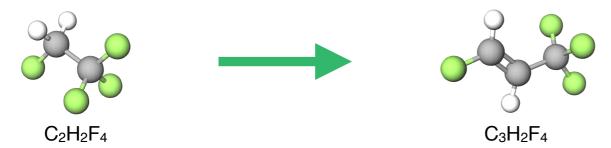

on behalf of the ALICE Collaboration

RPC workshop 2018

Puerto Vallarta — 21st February 2018

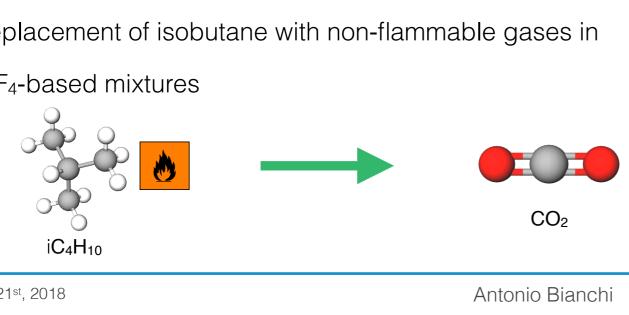

# Outline

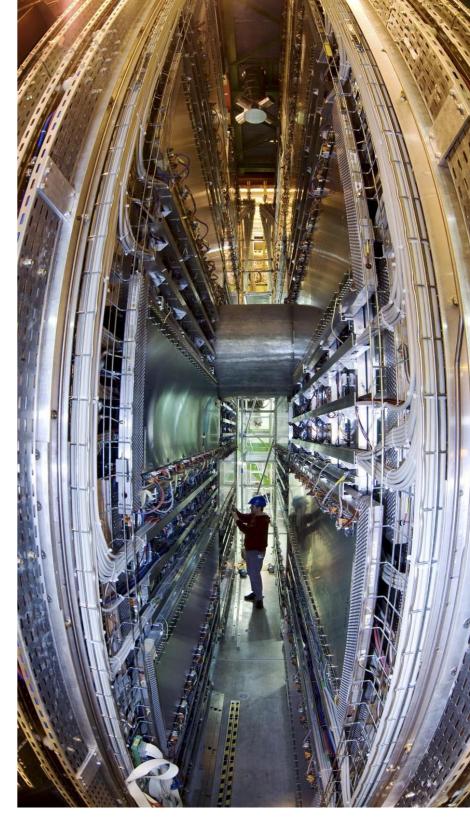

- R&D on eco-friendly gas mixtures for Resistive **Plate Chambers (RPCs):** 
  - → goal: a non-flammable mixture without greenhouse gases
- **Characterization of mixtures with HFOze:** 
  - → replacement of tetrafluoroethane with more eco-friendly gases
  - HFOze and CO<sub>2</sub> could act for a good solution instead of C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>

- Operation stability of RPCs with CO<sub>2</sub>-based mixtures:
  - → replacement of isobutane with non-flammable gases in

C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>-based mixtures

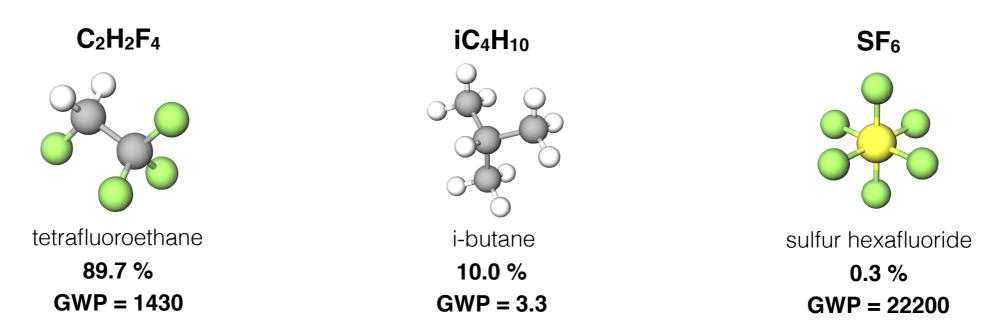

ALICE Muon Spectrometer Trigger Chambers

# Motivation

RPCs in the ALICE Muon Trigger are currently operating in maxi-avalanche mode at ~10300 V with:

Global Warming Potential (GWP): is the relative measure of how much heat a greenhouse gas traps in the atmosphere.  $GWP_{CO2} = 1 \text{ by definition}$ 

### Motivation for R&D studies on new gas mixtures for the forthcoming Muon Identifier at ALICE:

- security reasons: the current gas mixture is flammable
- reduction of greenhouse gas emissions into the atmosphere: the present gas mixture has a GWP = 1350
- cost saving: C<sub>2</sub>H<sub>2</sub>F<sub>4</sub> is being phased out by EU restrictions; SF<sub>6</sub> is banned except for research → possible rise of prices and limited future availability → the gas volume at ALICE is quite small (about 0.3 m³), nevertheless an alternative gas mixture is welcome
- the upgrade of front-end electronics is planned in view of Run 3 and enables to operate the RPCs in avalanche mode (talk: A. Ferretti, "The upgrade of the RPC-based ALICE Muon Trigger", RPC workshop 2018).

We have just started R&D studies on gas mixtures for possible upgrades in the future.

# Experimental approaches

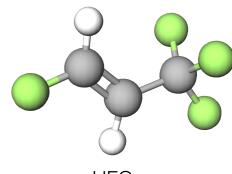

### 95% of the total GWP for the current ALICE mixture is due to the presence of C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>:

- hydrofluoroolefins (HFOs) may be appropriate candidates to replace C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>, thanks to their very low GWPs:
  - HFOze and CO<sub>2</sub> could act for a good solution instead of C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>
  - chemical structure of HFOze (C=C-C) suggests a good capability to absorb photons
- experimental tests are ongoing in Torino to:
  - check the RPC performance with new eco-friendly mixtures
  - identify some promising gas mixtures for the requirements of the ALICE Muon Identifier
- as next step, long-time stability tests of new gas mixtures to check rate capability and performance (aging issue)

### The high concentration of iC<sub>4</sub>H<sub>10</sub> makes the ALICE mixture flammable:

CO<sub>2</sub>

- ongoing tests with CO<sub>2</sub> instead of iC<sub>4</sub>H<sub>10</sub> to avoid the use of flammable gases:
  - → non-flammable components would be advisable to make the operation of detectors simpler and safer
- medium-term stability of detectors has been tested with cosmic-ray flux

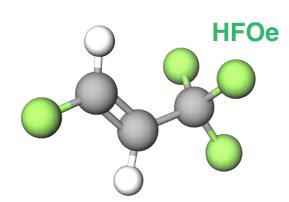

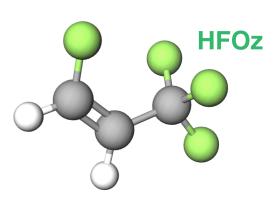

**HFOze** 

# Guideline for HFOze and CO<sub>2</sub>

### HFOze:

- tetrafluoropropene (*C*<sub>3</sub>*H*<sub>2</sub>*F*<sub>4</sub>):
  - → it is an **olefin** (double bond in the chain of carbon atoms)
  - $\rightarrow$  two isomers (z = hydrogen atoms on the same side, whereas e = hydrogen atoms on opposite side)
  - → isomers **z** and **e** have slightly different physical proprieties (i.e. boiling points) but similar electrical properties; different batches can contain different concentration of HFOz (10-30%)
- GWP < 1 (revision at 5th IPCC)
- it is not flammable at room temperature
- the strong electron attachment makes HFOze a promising gas for electric insulation:
  - → in particular for high voltage gaseous insulation equipments (doi:10.1088/0963-0252/25/4/045005)

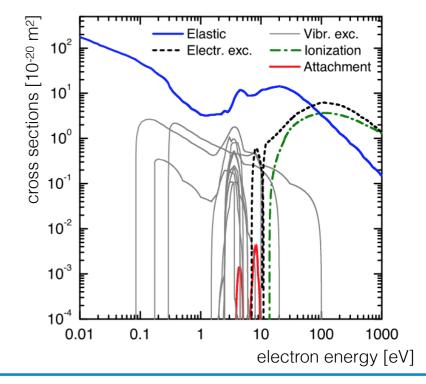

### Carbon dioxide:

- CO<sub>2</sub>
- GWP = 1 by definition
- it is not flammable
- cluster density = 34/cm
- ionization potential = 13.8 eV
- photon absorption > 11 eV
- · weak attachment coefficient

# photoabsorption cross section for CO<sub>2</sub> (qq) 100 100 40 20 x 10 10 12 14 Photon energy (eV)

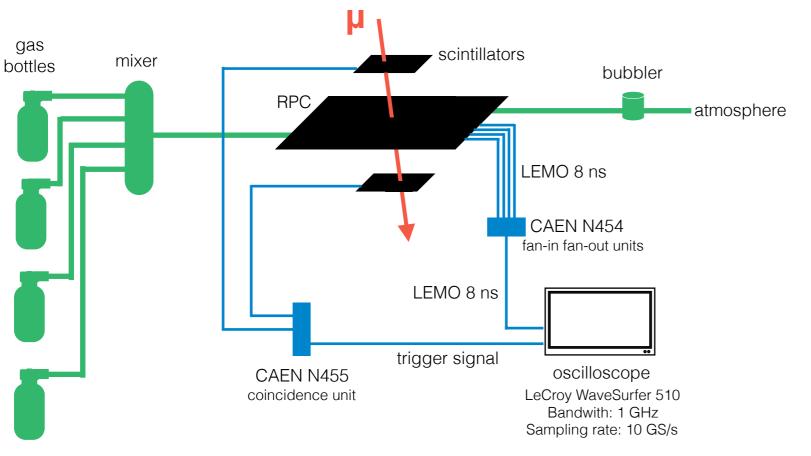

cross sections between electrons and CO<sub>2</sub>

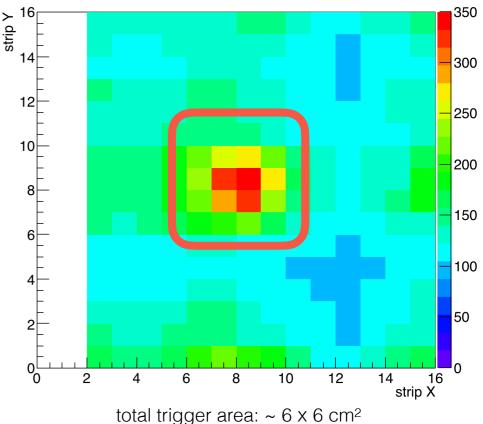

# Experimental set-up

### R&D studies on eco-friendly gas mixtures:

- two small-size (50 x 50 x 0.2 cm<sup>3</sup>) RPCs inside a Faraday cage
- read-out strips (2  $\times$  50 cm<sup>2</sup>) which are terminated with 50  $\Omega$  resistors
- trigger: four scintillators coupled with photomultipliers
- the HV is applied with temperature and pressure correction
- gas mixture:
  - → possibility to mix at maximum 4 different gases
  - → it is dry: the resistance of bakelite is kept optimal, flowing the RPCs with wet mixture every 10/15 days

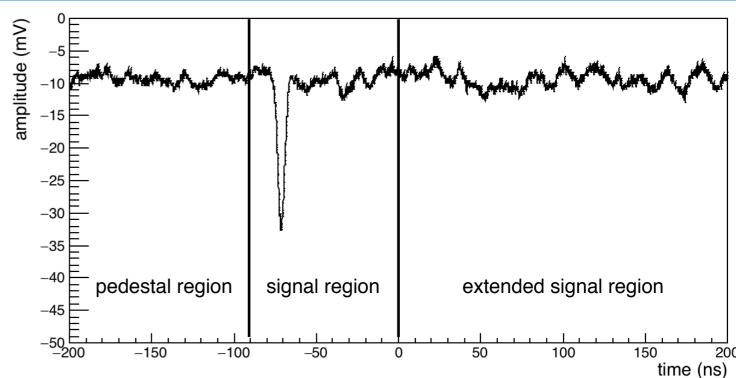

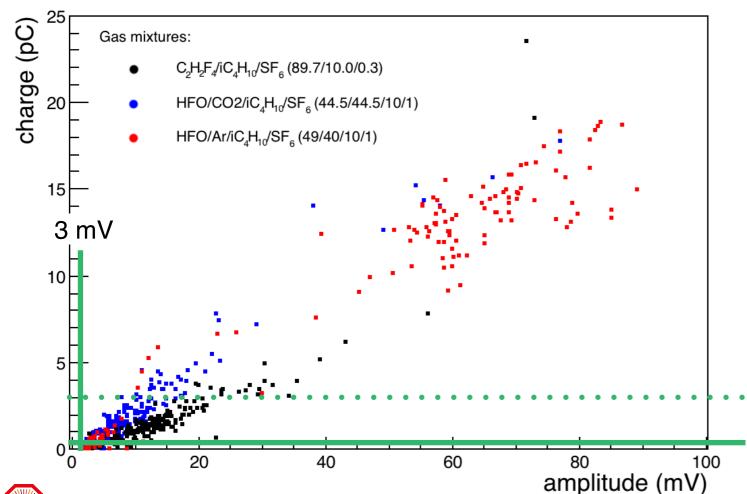

# Signal analysis

### Three regions for the signal analysis:

- the pedestal region to define the voltage baseline
- the signal region to calculate the charge and the amplitude
- extended signal region to check possible after pulses

### Thresholds used for the analysis:

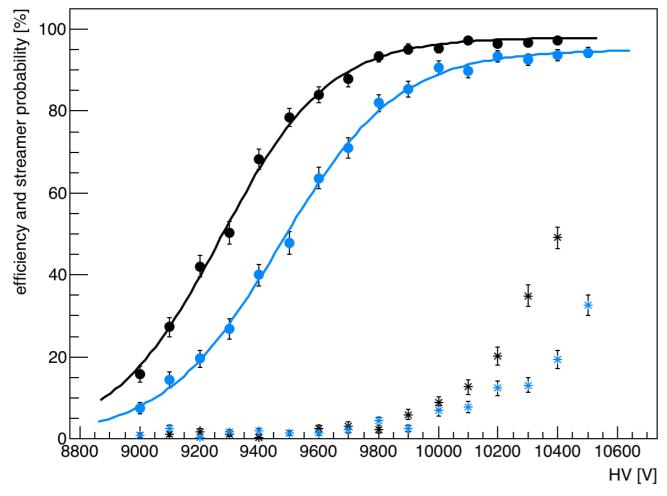

• efficiency:

Q<sub>induced</sub> > 0.3 pC and amplitude > 3 mV (corrected by baseline)

streamer: Q<sub>induced</sub> > 3 pC

## Characterization with standard mixtures

ALICE mixture  $(C_9H_2F_4/iC_4H_{10}/SF_689.7/10.0/0.3)$ :

efficiency

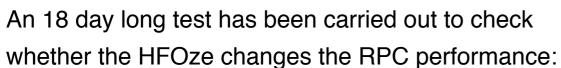

\* streamer probability

ATLAS-CMS mixture ( $C_2H_2F_4/iC_4H_{10}/SF_6$  95.2/4.5/0.3):

efficiency

\* streamer probability

The RPC has been characterized with the most common gas mixtures used at LHC

→ no hints of negative effects observed (same efficiency curves and no increase of current during the test)

Mixture Ar/HFOze/i $C_4H_{10}/SF_6$  (40/49/10/1):

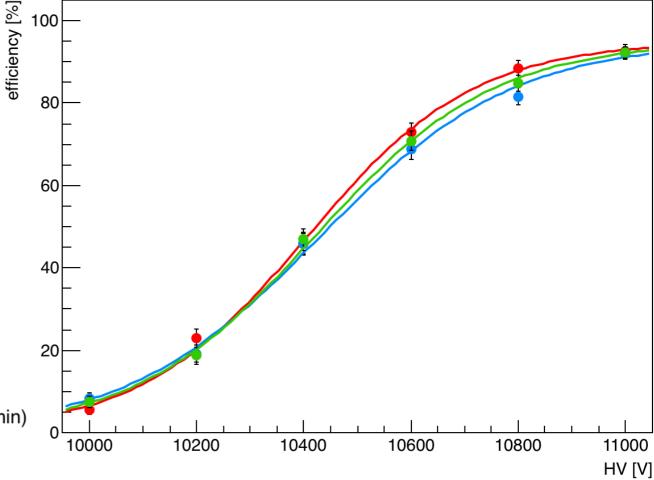

efficiency on 06/11/2017

for 9 days RPC off (gas flow = 50 cc/min)

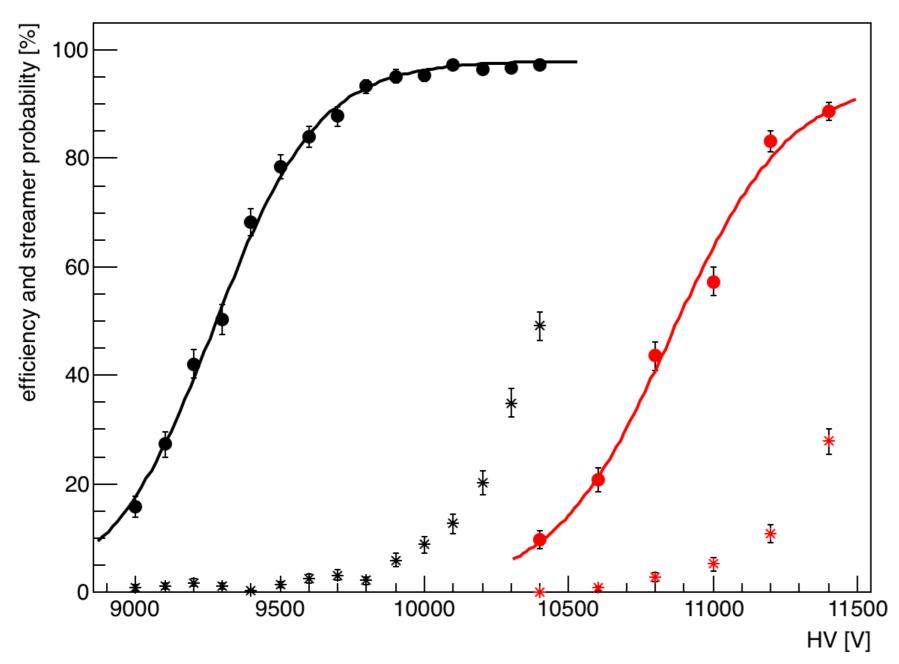

efficiency on 15/11/2017

for 9 days RPC at 10500 V (gas flow = 50 cc/min)

efficiency on 24/11/2017

ALICE mixture (C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>/iC<sub>4</sub>H<sub>10</sub>/SF<sub>6</sub> 89.7/10.0/0.3):

efficiency

\* streamer probability

Mixture CO<sub>2</sub>/HFOze/iC<sub>4</sub>H<sub>10</sub>/SF<sub>6</sub> (44.5/45.2)10.0/0.3):

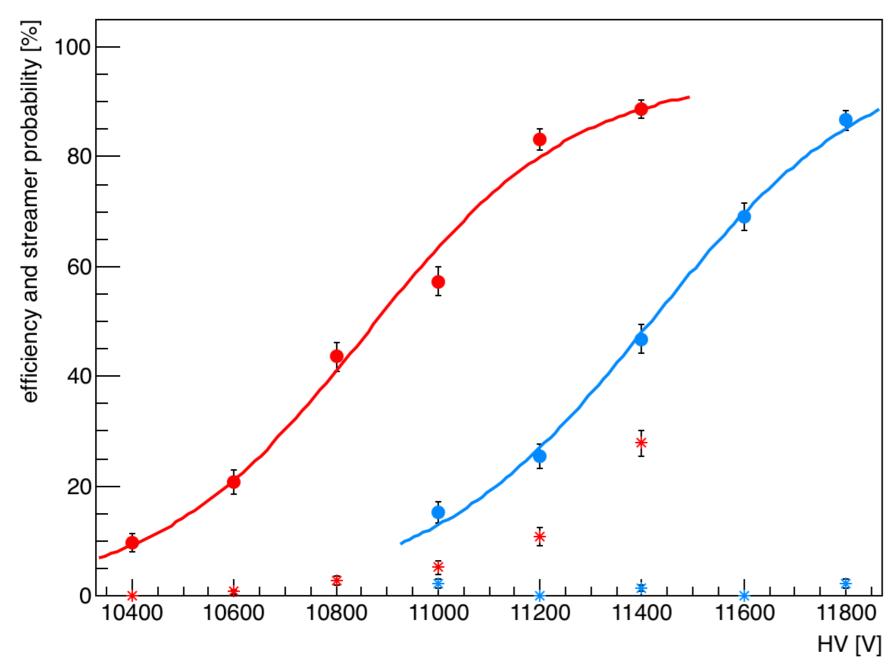

efficiency

\* streamer probability

### Mixture CO<sub>2</sub>/HFOze/iC<sub>4</sub>H<sub>10</sub>/SF<sub>6</sub> (44.5/45.2/10.0/0.3):

- the concentrations of iC<sub>4</sub>H<sub>10</sub> and SF<sub>6</sub> are equal to the ones in the ALICE mixture
- 89.7% C<sub>2</sub>H<sub>2</sub>F<sub>4</sub> has been replaced by 44.5% CO<sub>2</sub> and 45.2% HFOze
- the working point is shifted by about 1500 V and the streamer probability is increased

Mixture CO<sub>2</sub>/HFOze/iC<sub>4</sub>H<sub>10</sub>/SF<sub>6</sub> (44.5/45.2/10.0/0.3):

efficiency

streamer probability

Mixture CO<sub>2</sub>/HFOze/iC<sub>4</sub>H<sub>10</sub>/SF<sub>6</sub> (44.5/44.5/10.0/1.0)

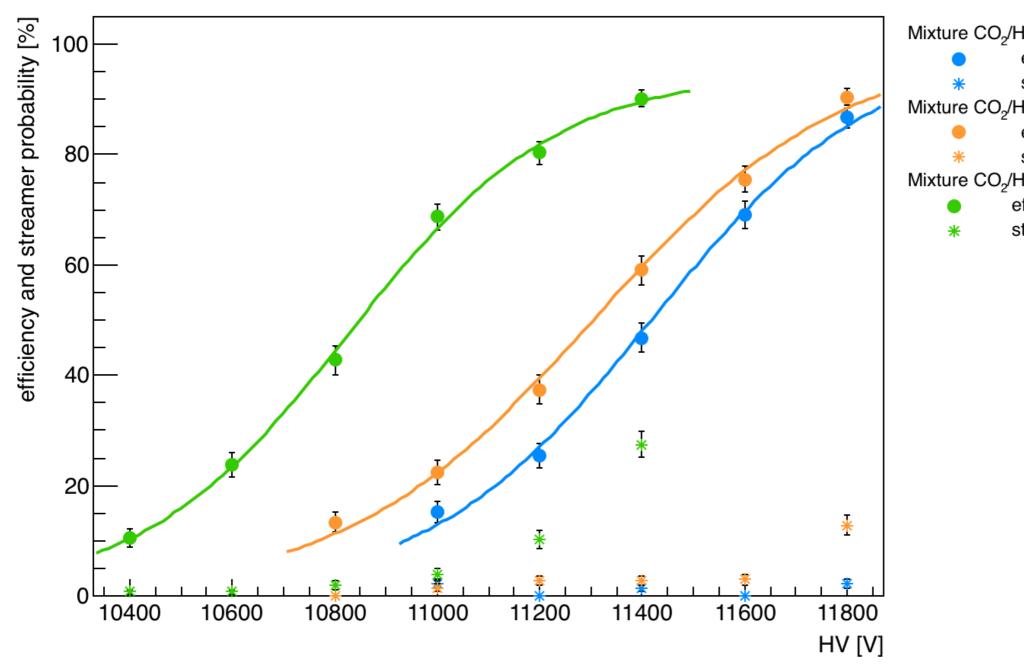

efficiency

streamer probability

Mixture  $CO_2/HFOze/iC_4H_{10}/SF_6$  (44.5/44.5/10.0/1.0):

- · 0.7% increase of SF6 → working point: + 500 V and streamer probability (@ eff. = 90%) < 5%
- **GWP = 223:** six times lower than the current ALICE mixture (1350)

Mixture CO<sub>2</sub>/HFOze/iC<sub>4</sub>H<sub>10</sub>/SF<sub>6</sub> (44.5/44.5/10.0/1.0):

efficiency

streamer probability

Mixture CO<sub>2</sub>/HFOze/iC<sub>4</sub>H<sub>10</sub>/SF<sub>6</sub> (39.5/44.5/15.0)1.0):

efficiency

streamer probability

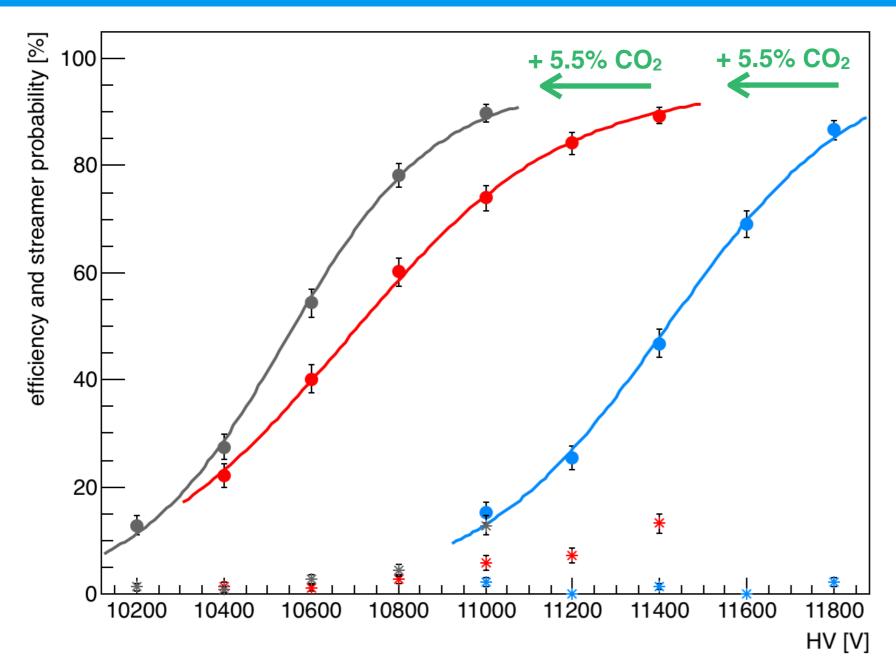

Mixture CO<sub>2</sub>/HFOze/iC<sub>4</sub>H<sub>10</sub>/SF<sub>6</sub> (44.5/39.5/15.0)1.0):

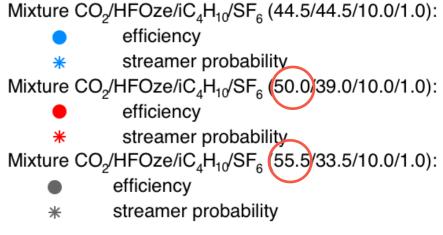

efficiency

streamer probability

### Increasing the concentration of $iC_4H_{10}$ :

- same concentration of HFOze as the previous mixture → small change in working point; slightly increase of streamers
- 5% decrease of HFOze → working point: + 500 V and streamer probability (@ eff. = 90%): 25%

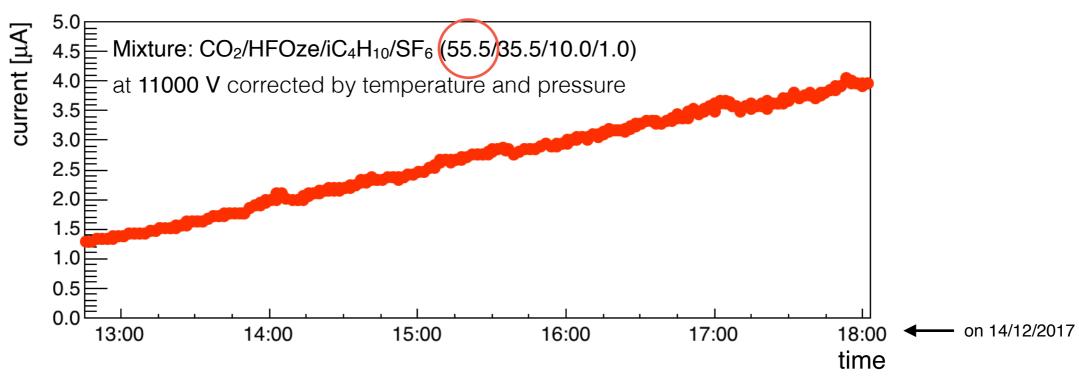

### Ratio between CO<sub>2</sub> and HFOze changes:

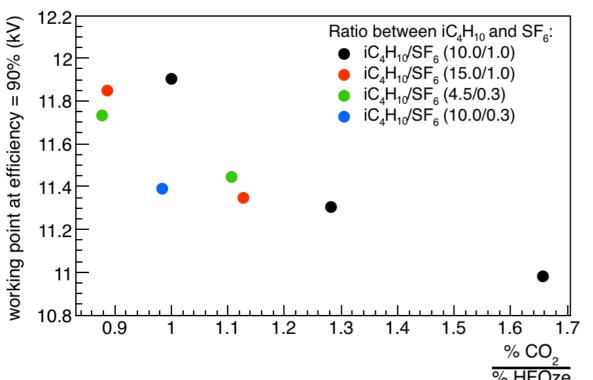

- if the concentration of **CO<sub>2</sub> increases**, the working point decreases, whereas the streamer probability increases up to 10% (with efficiency equal to 90%)
- if the concentration of CO<sub>2</sub> is equal to 55.5%, the current is not stable at constant voltage

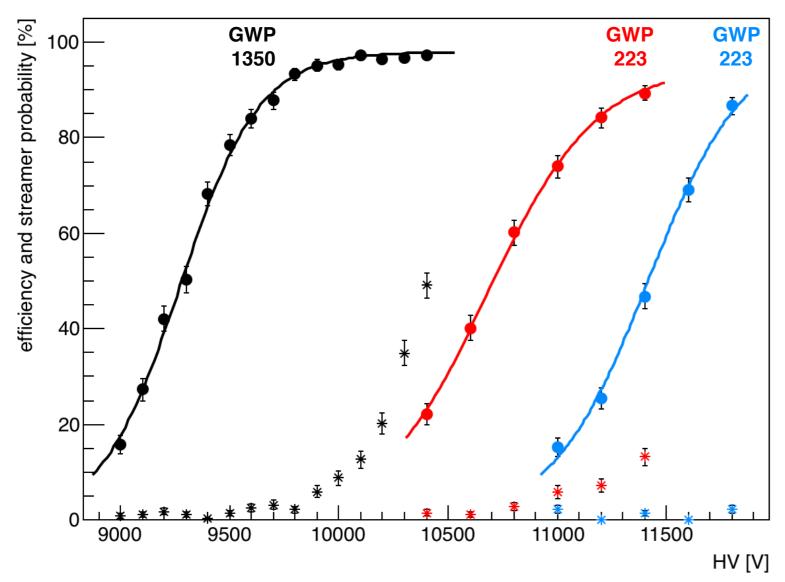

The addition of CO<sub>2</sub> into HFO-based mixtures reduces the working point:

• +10% of  $CO_2 \rightarrow$  -1000 V in working point but unstable current if  $CO_2 = 55.5\%$ 

CO <sub>2</sub> (%)	HFOze (%)	iC <sub>4</sub> H <sub>10</sub> (%)	SF <sub>6</sub> (%)	CO <sub>2</sub> /HFOze	working point	stable current
44,5	44,5	10	1	1,00	11902 V	yes
50	39	10	1	1,28	11306 V	yes
55,5	33,5	10	1	1,66	10981 V	no
39,5	44,5	15	1	0,89	11851 V	yes
44,5	39,5	15	1	1,13	11349 V	yes
44,5	50,7	4,5	0,3	0,88	11734 V	yes
50	45,2	4,5	0,3	1,11	11448 V	yes
44,5	45,2	10	0,3	0,98	11391 V	yes

# Promising mixtures

ALICE mixture  $C_2H_2F_4/iC_4H_{10}/SF_6$  (89.7/10.0/0.3):

• efficiency

\* streamer probability

Mixture  $CO_2/HFOze/iC_4H_{10}/SF_6$  (44.5/44.5/10.0/1.0):

• efficiency

\* streamer probability

Mixture  $CO_2/HFOze/iC_4H_{10}/SF_6$  (50.0/39.0/10.0/1.0):

• efficiency

\* streamer probability

### Issues:

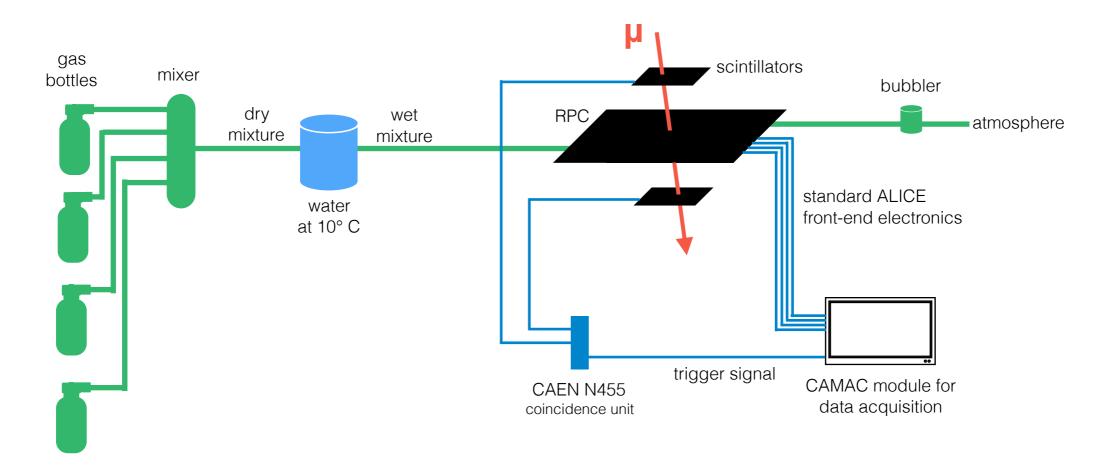

- the working point stays high
   (threshold = 3 mV and minimum charge = 0.3 pC)
- in some gas mixtures, the streamer probability is too high (charge signal > 3 pC)

### However:

- the new front-end electronics (with amplification) allows to achieve the maximum detector efficiency at lower values of electric field, in which streamers have smaller chance to develop
  - → hints of stability problems have been observed with large amount of CO₂ (to be investigated further)

# Stability of RPCs without flammable gases

**Motivation:** necessity to remove flammable gas in the current ALICE mixture, in particular we evaluated whether the CO<sub>2</sub> might have been a suitable substitute of iC<sub>4</sub>H<sub>10</sub>

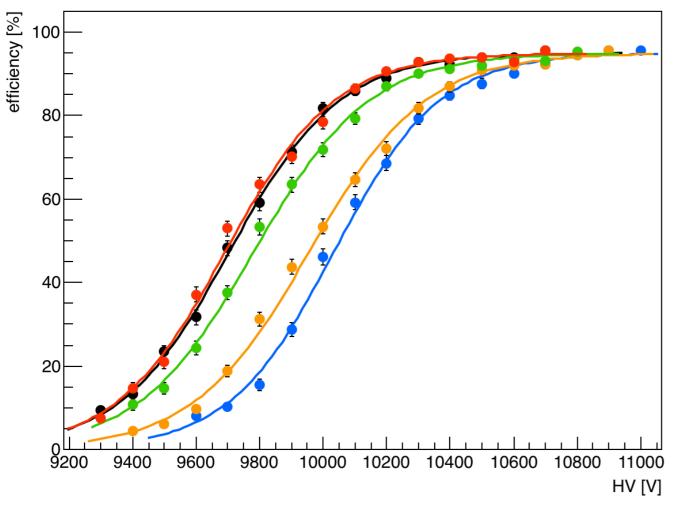

### Experimental set-up:

- for the data acquisition, the standard ALICE front-end electronics has been used (threshold = 7 mV, no amplification)
- trigger on cosmic-ray flux (4 scintillators in coincidence)
- in the gas mixture, the only replacement is the use of CO2 instead of iC4H10 in different concentrations
- the gas mixture is wet (the mixture bubbles in water at 10° C)

# Operation of RPCs with CO<sub>2</sub>-based mixtures

After the characterization of RPCs with ALICE mixture, we changed the iC<sub>4</sub>H<sub>10</sub> with different concentrations of CO<sub>2</sub>:

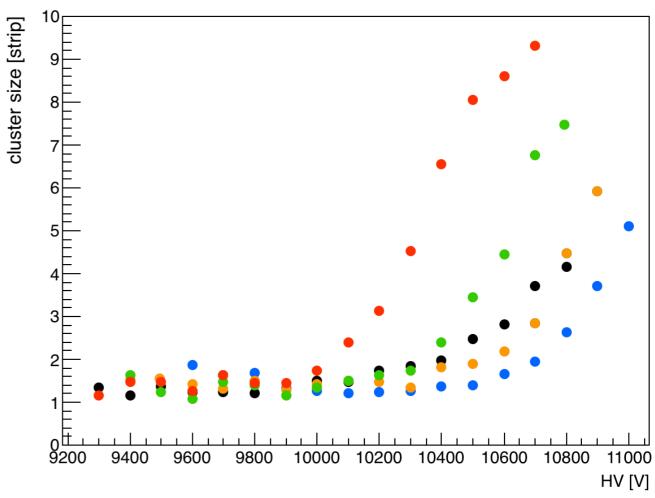

### Issues:

- the cluster size with CO<sub>2</sub>-based mixtures results in being higher than with the current ALICE mixture
- CO<sub>2</sub> does not appear to be a suitable photon quencher to replace iC<sub>4</sub>H<sub>10</sub> in C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>-based mixtures

### Mixtures:

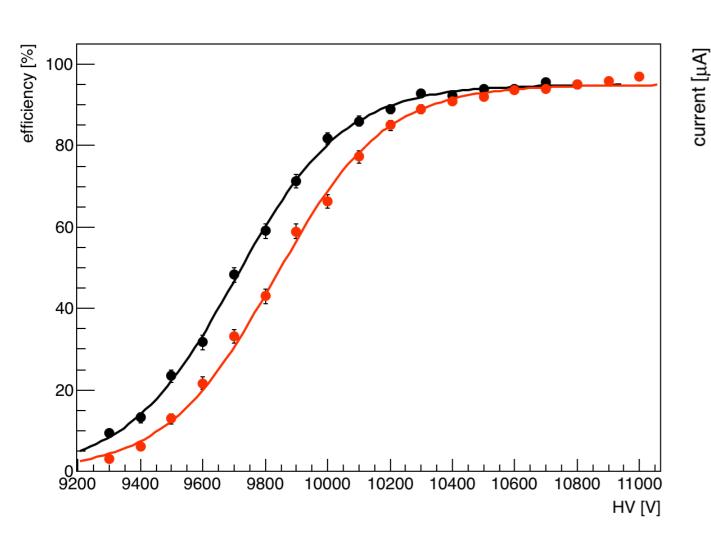

- ALICE mixture  $C_2H_2F_4/iC_4H_{10}/SF_6$  (89.7/10.0/0.3)
- $C_2H_2F_4/CO_2/SF_6$  (96.7/3.0/0.3)
- C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>/CO<sub>2</sub>/SF<sub>6</sub> (94.7/5.0/0.3)
- C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>/CO<sub>2</sub>/SF<sub>6</sub> (89.7/10.0/0.3)
- C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>/CO<sub>2</sub>/SF<sub>6</sub> (75.7/24.0/0.3)

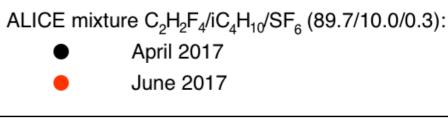

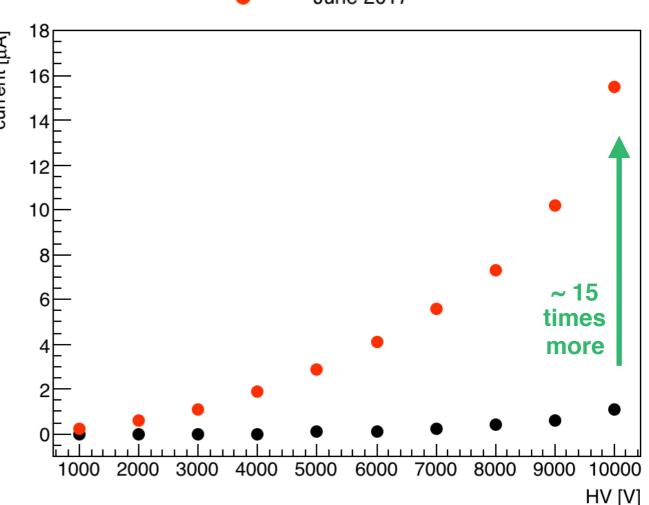

# Operation stability of RPCs with ALICE mixture

### After about two months of operation with CO<sub>2</sub> in C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>-based mixtures:

- the efficiency curve is shifted by about 100 V
- a huge increase in current has been observed

### The issue on the operation stability is under investigation:

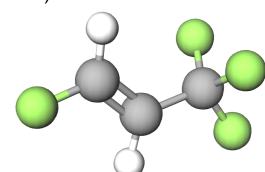

gas quality, environmental conditions, humidity, chemical reactions between bakelite/linseed oil with CO<sub>2</sub>, chemical reactions between CO<sub>2</sub> and the other components of mixture, damages due to the high photons flux and etc.

# Conclusions and outlooks

### • R&D on eco-friendly gas mixtures:

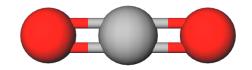

- → goal: to have a non-flammable mixture without greenhouse gases (at least with a low GWP)
- → HFOze is a possible candidate to substitute C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>, thanks to its low GWP
- → interest to substitute totally or partially iC<sub>4</sub>H<sub>10</sub>, because it is a flammable gas

### Characterization of mixtures with HFOze:

several tests on HFO-based mixtures with addition of various gases are ongoing and encouraging results have already been obtained (i.e. addition of CO<sub>2</sub>):

- the addition of CO<sub>2</sub> to HFOze is required to operate at lower values of electric field
- some of HFOze/CO<sub>2</sub>-based mixtures are promising but cluster size and time resolution are not already measured and long-time stability tests are required to check:
  - rate capability
  - effect of background radiation
  - long term performance (aging issue)

### Operation stability of RPCs with CO<sub>2</sub>-based mixtures:

- → CO<sub>2</sub> does not appear to be a suitable photon quencher to replace iC<sub>4</sub>H<sub>10</sub> in C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>-based mixtures
- → an increase in current has been observed after two months of operation with cosmic-ray flux
- → further tests are fundamental to check the compatibility of CO<sub>2</sub> in gas mixtures for RPCs
