

# TileCal PMT Response to Laser Pulses Sent in Empty Bunches During Physics Runs

Summer Zuber, July 20, 2017

University of California, Santa Cruz

Tutors: Dr Fabrizio Scuri, Dr Henric Wilkens

# Quick Reminder...

# PMT Response Evolution Behavior: Expectations

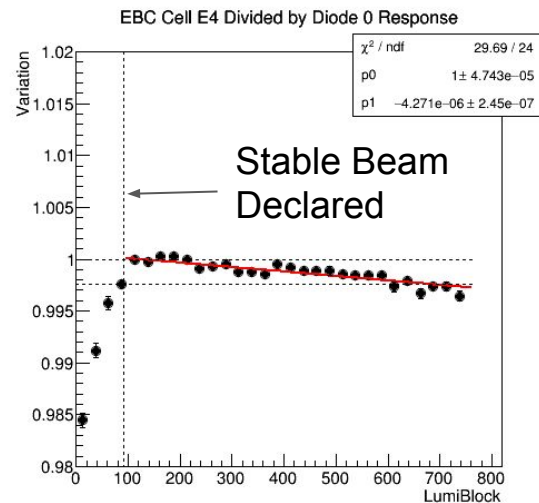

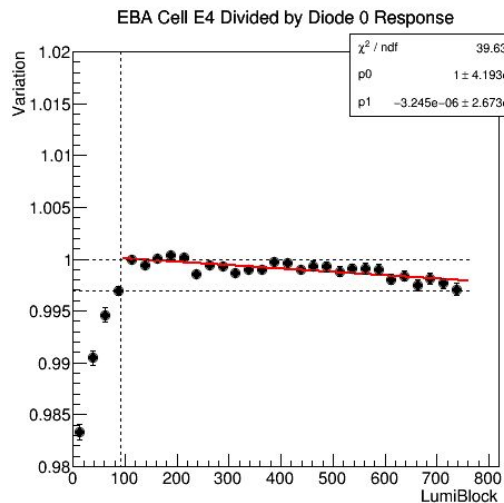

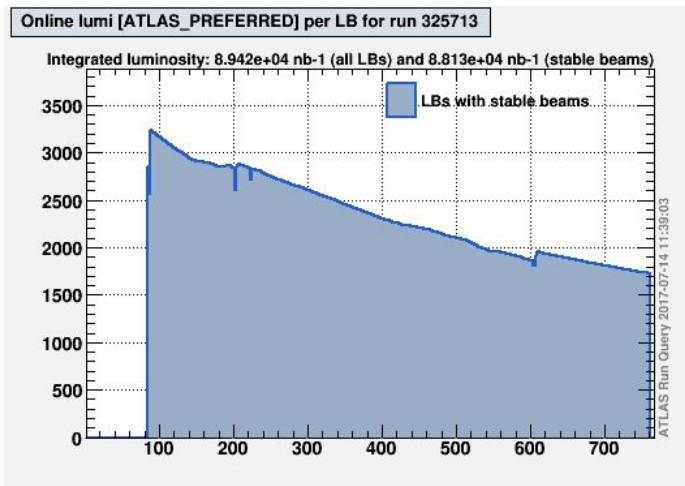

In 2015-2016 there was a clear jump observed in the time profile of the PMT response when stable beams are declared

The size of the jump was clearly correlated with the peak luminosity of the run

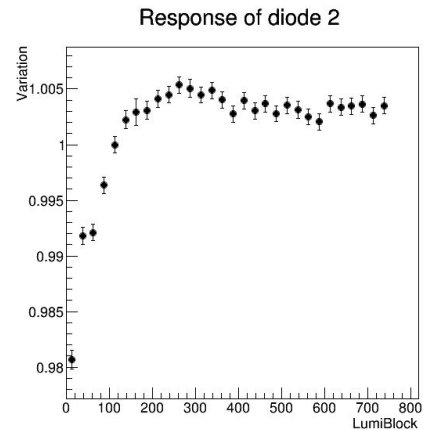

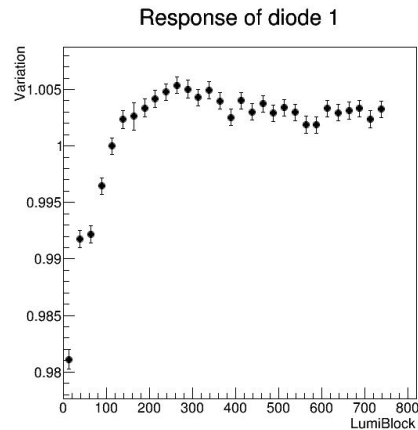

This preliminary study looks at the behavior of the time profile of the PMT response in the 2017 collision data so far

CAVEAT: Most collision runs so far have been used in machine studies in which the beam parameters are changed, even after stable beams are declared

# Run 325713: An example of expected time profile

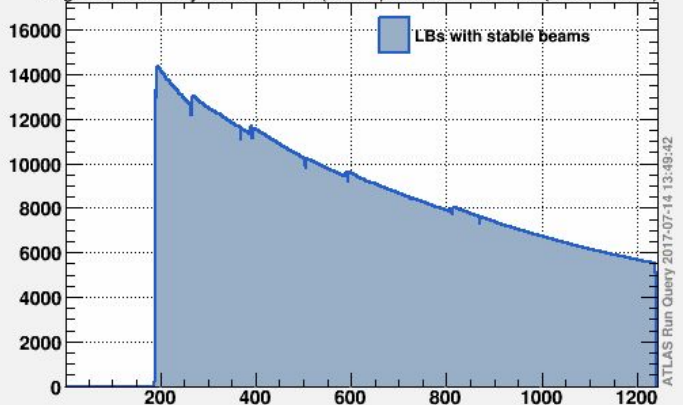

## Laser Intensity Monitors:

# Run 327764: An example of anomalous time profile

Online lumi [ATLAS\_PREFERRED] per LB for run 327764

Integrated luminosity: 5.28e+05 nb<sup>-1</sup> (all LBs) and 5.248e+05 nb<sup>-1</sup> (stable beams)

EBA Cell E4 Divided by Diode 0 Response

EBC Cell E4 Divided by Diode 0 Response

Response of diode 0

Response of diode 1

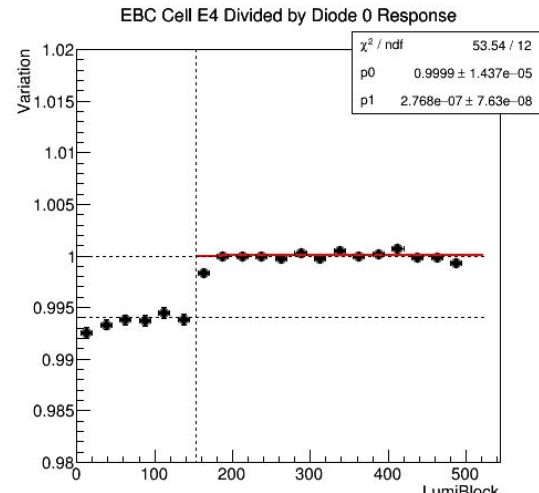

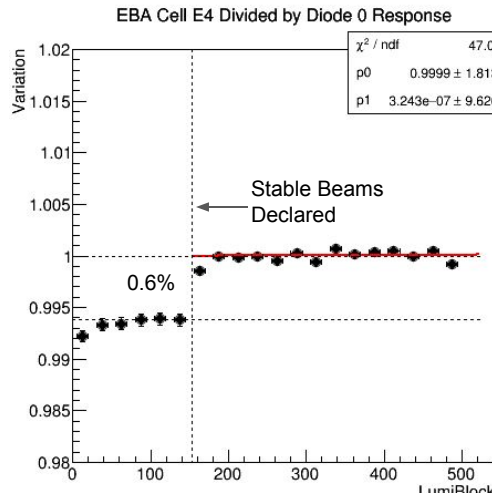

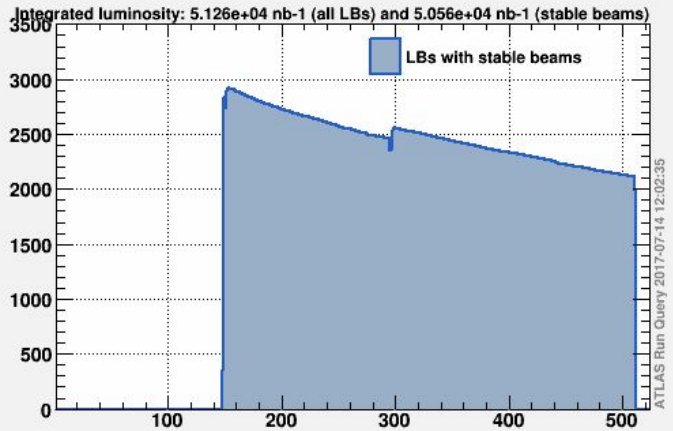

Response of diode 2

# Run 325790: An example of clear jump at stable beam declaration

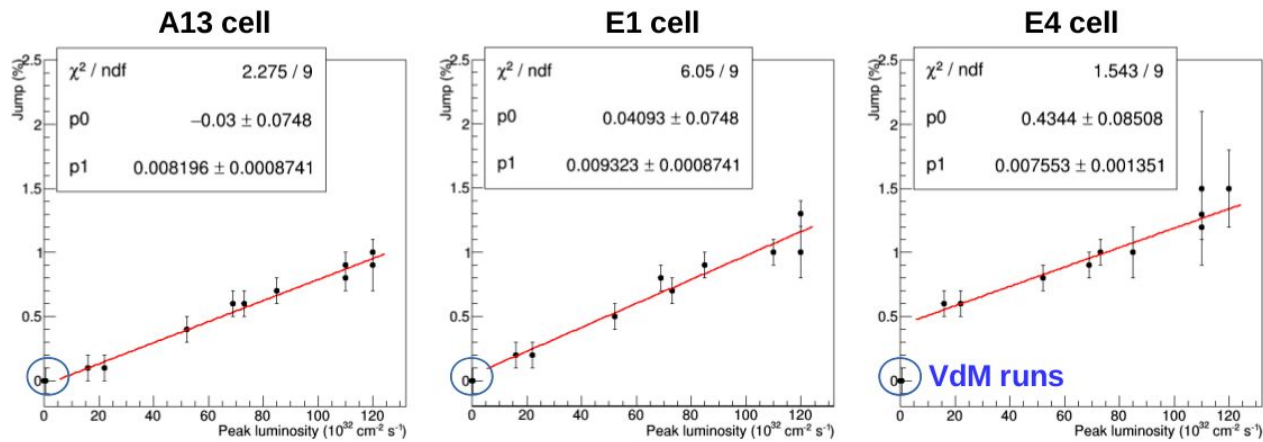

Online lumi [ATLAS\_PREFERRED] per LB for run 325790

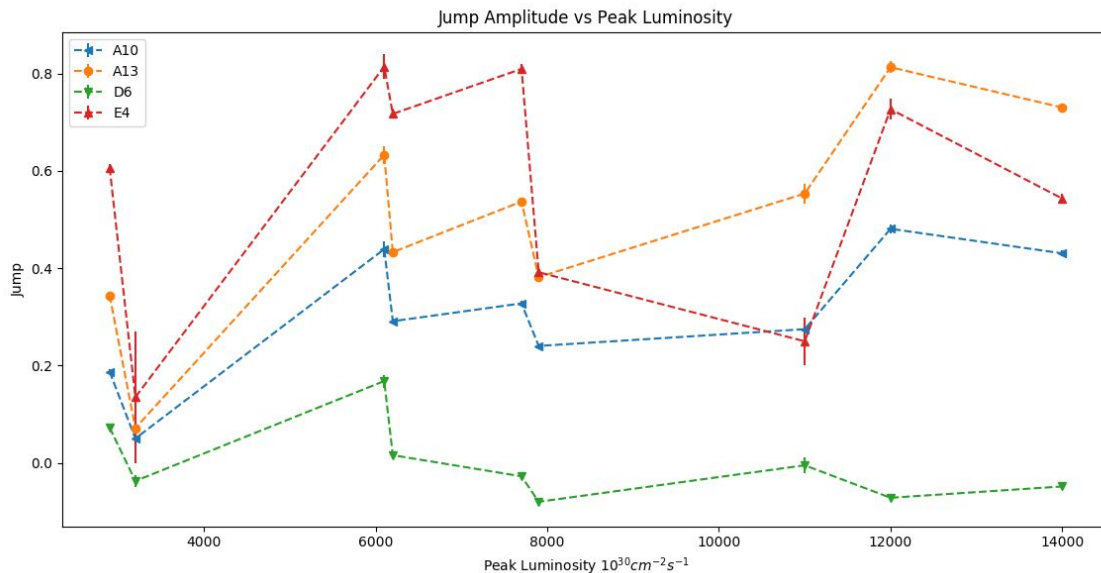

Laser Intensity Monitors:

## 2015-2016 Analysis of Jump Amplitude:

## 2017 Analysis of Jump Amplitude:

# Conclusions and Further Study

So far no correlation between jump amplitude and peak luminosity observed

Analysis of the jump amplitude should be repeated using collision runs with stable beam conditions

There is a correlation between the cell exposure and the jump size

PMT Response Evolution between Calibration Runs:

Comparing Average PMT Response of Last Calibration Run to PMT Response Right After Stable Beam in Physics Run

Construct observables: 
$$\Delta = \frac{2(PHY - \overline{CAL})}{PHY + \overline{CAL}} \quad \Delta_0 = \frac{2(PHY_0 - \overline{CAL}_0)}{PHY_0 + \overline{CAL}_0}$$

And study Correlation with parameters such as time elapsed between calibration and physics

Backup

# Laser Pulses in LHC Empty Bunches

In the LHC there are two beams circling in opposite directions

The protons of each beam are grouped into bunches separated by 25 ns

There are intervals of 25 ns with no protons i.e. “empty bunches”

At the time in which empty bunches intersect at an interaction point laser pulses are sent to all TileCal channels

**LB**

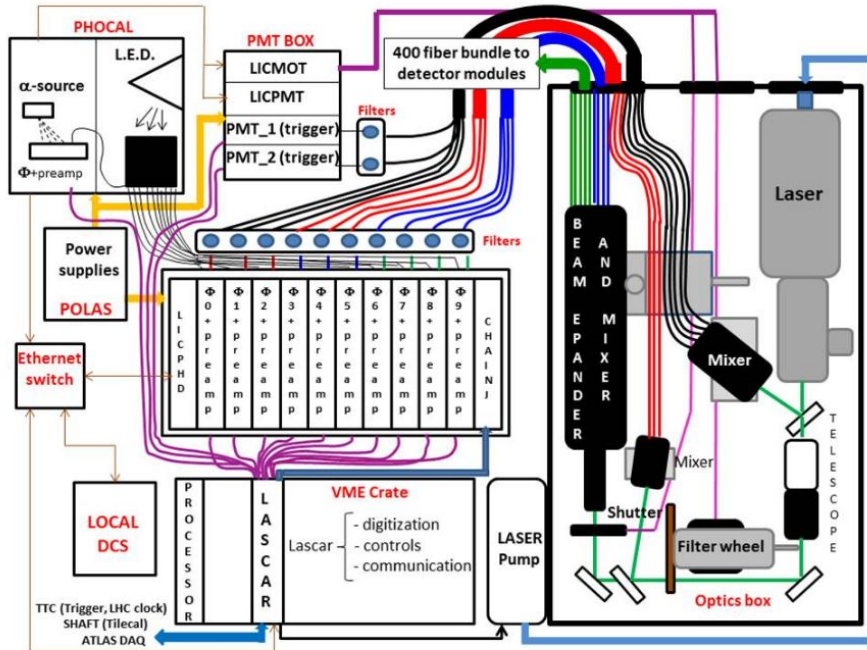

**EB**

*beam axis* →

# Laser Calibration

The full LaserII system:

Laser is used to send laser pulses to all 10,000 PMTs via optical fibers

The response of each PMTs can be normalised to the response of a monitor diode just downstream of the laser

# Skills to Gain this Summer:

Knowledge of operation of a hadronic calorimeter

Knowledge of calibration systems for sub-detectors

Knowledge in C++ programming for developing analysis algorithms

Knowledge of using the ROOT software package

# Physics Runs

Exclude all bad PMTs

Total response of each event divided by response of diode 0 (for each individual pmt)

Average over all events in 25 LumiBlock period (for each individual pmt)

Normalize to first bin of stable beam

Take Mean over all modules for a given cell over a given 25 LumiBlock period

Plot response versus LumiBlock → evolution of the response

# Normal Calibration Runs

Divide into 10 bins of equal number of events ~ 10 second bins

# Special Calibration Runs

Bins of ~ 5 LumiBlock by assuming ~ 180 events per LumiBlock
