

OPTICS STUDIES FOR ATLAS FORWARD PROTON PROJECT

Tom Eichlersmith

Adivisor: Maciej Trzebinski

Thanks to: Grzegorz Gach and the National
Science Foundation

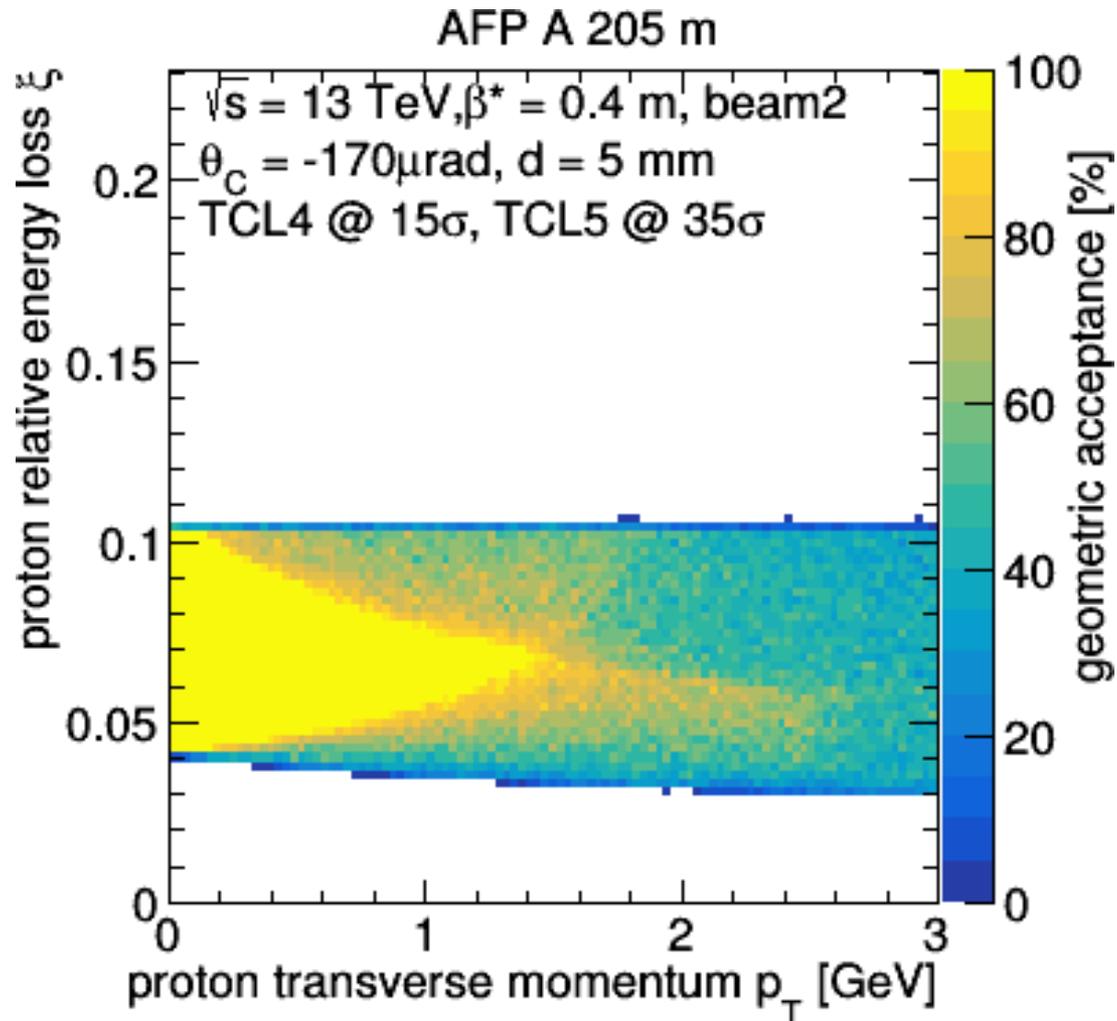

Purpose

- Previously, many separate codes to produce plots and files related to optic settings
- This framework unifies them into one library

Capabilities

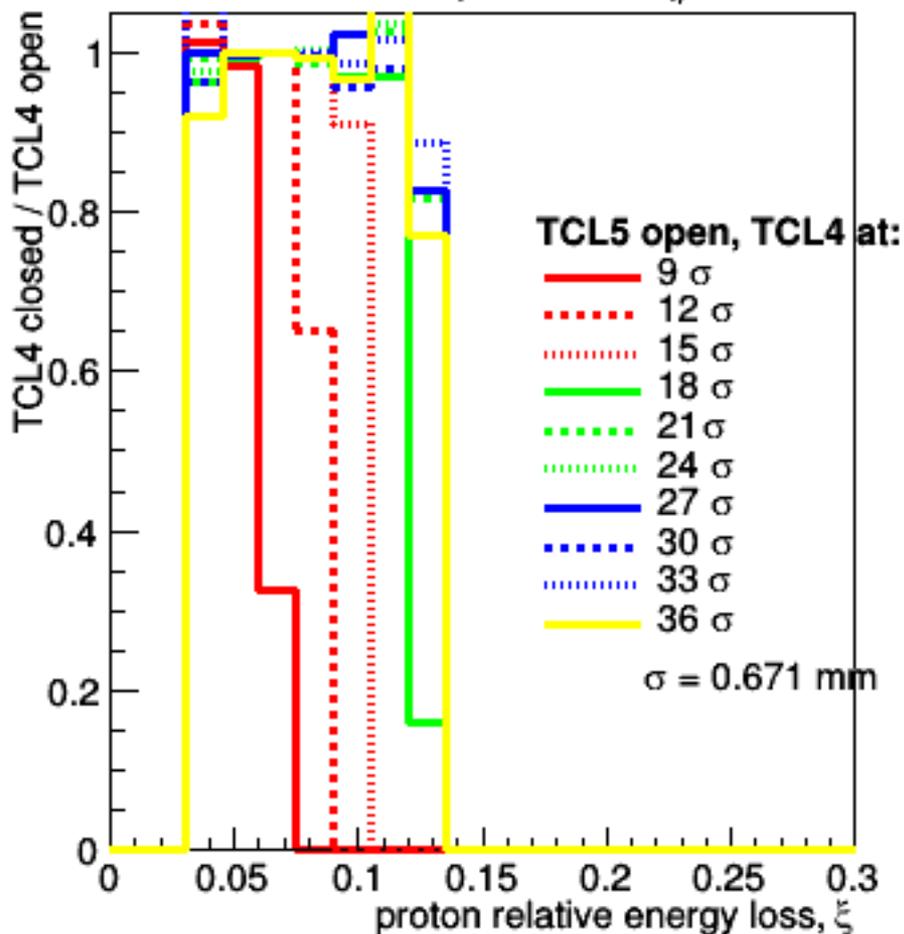

- Generate twiss files from MAD-X files (using MAD-X)
 - Assumes UNIX machine
- Geometric acceptance plots
- Collimator analysis plots
- Example proton positions in detector plane
- Example trajectories
- Probabilities of a single tag and double tag event as functions of pileup
- Probabilities of hitting floor of Roman pot
- Determine transport parameterization, print to file, compare parameterization to simulation
- Saves generated histograms to .root file
- Prints plots as both .png and .eps files

example.GeometricAcceptance()

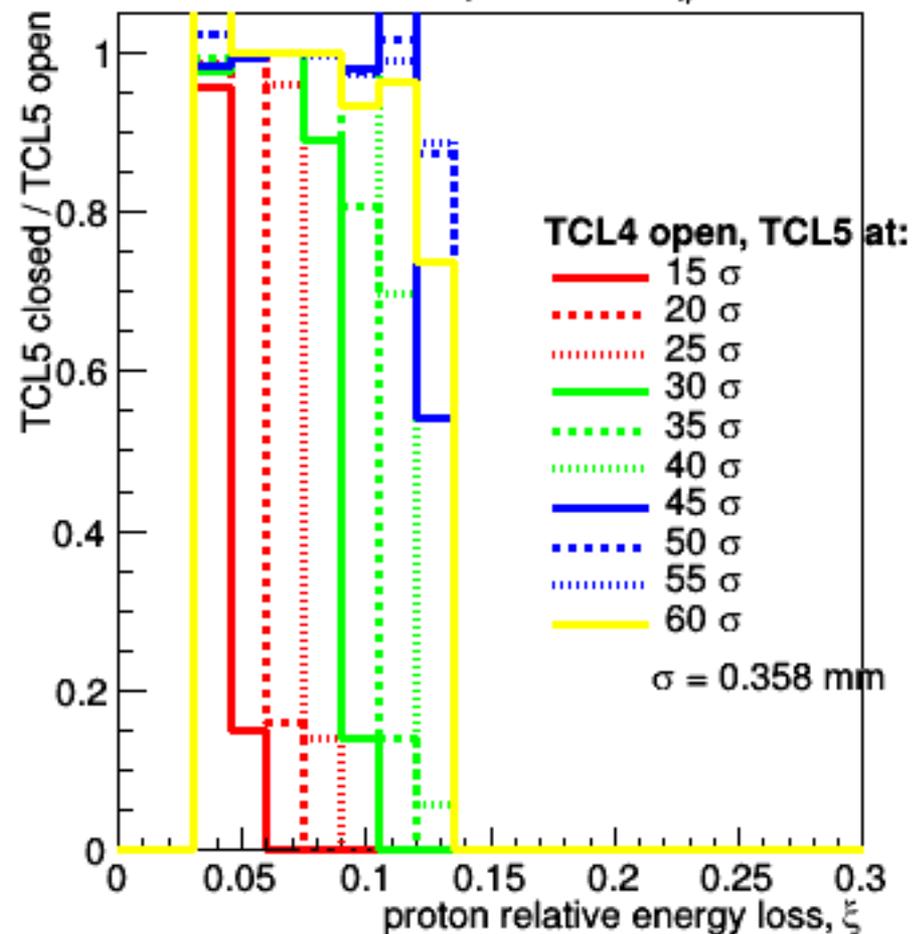

example.CollimatorAnalysis()

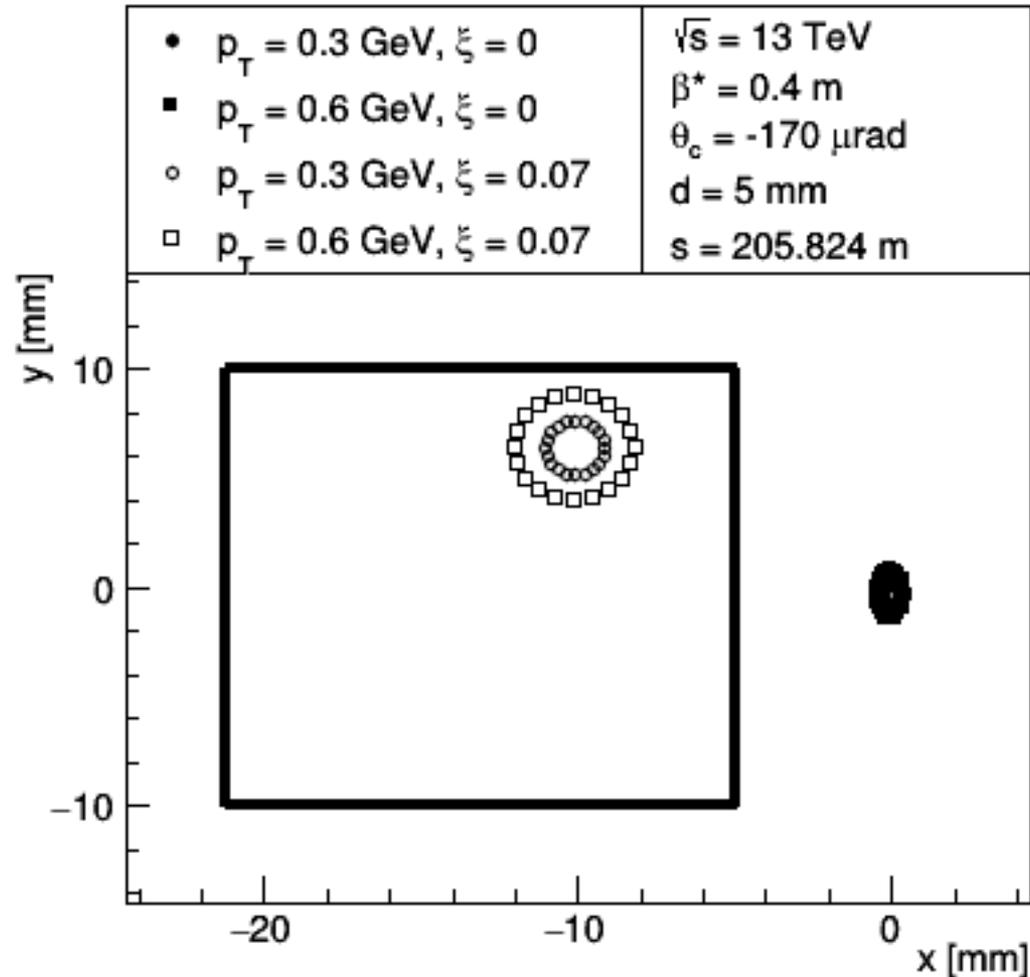

AFP A 205 m, $\sqrt{s} = 13$ TeV, $\beta^* = 0.4$ m

AFP A 205 m, $\sqrt{s} = 13$ TeV, $\beta^* = 0.4$ m

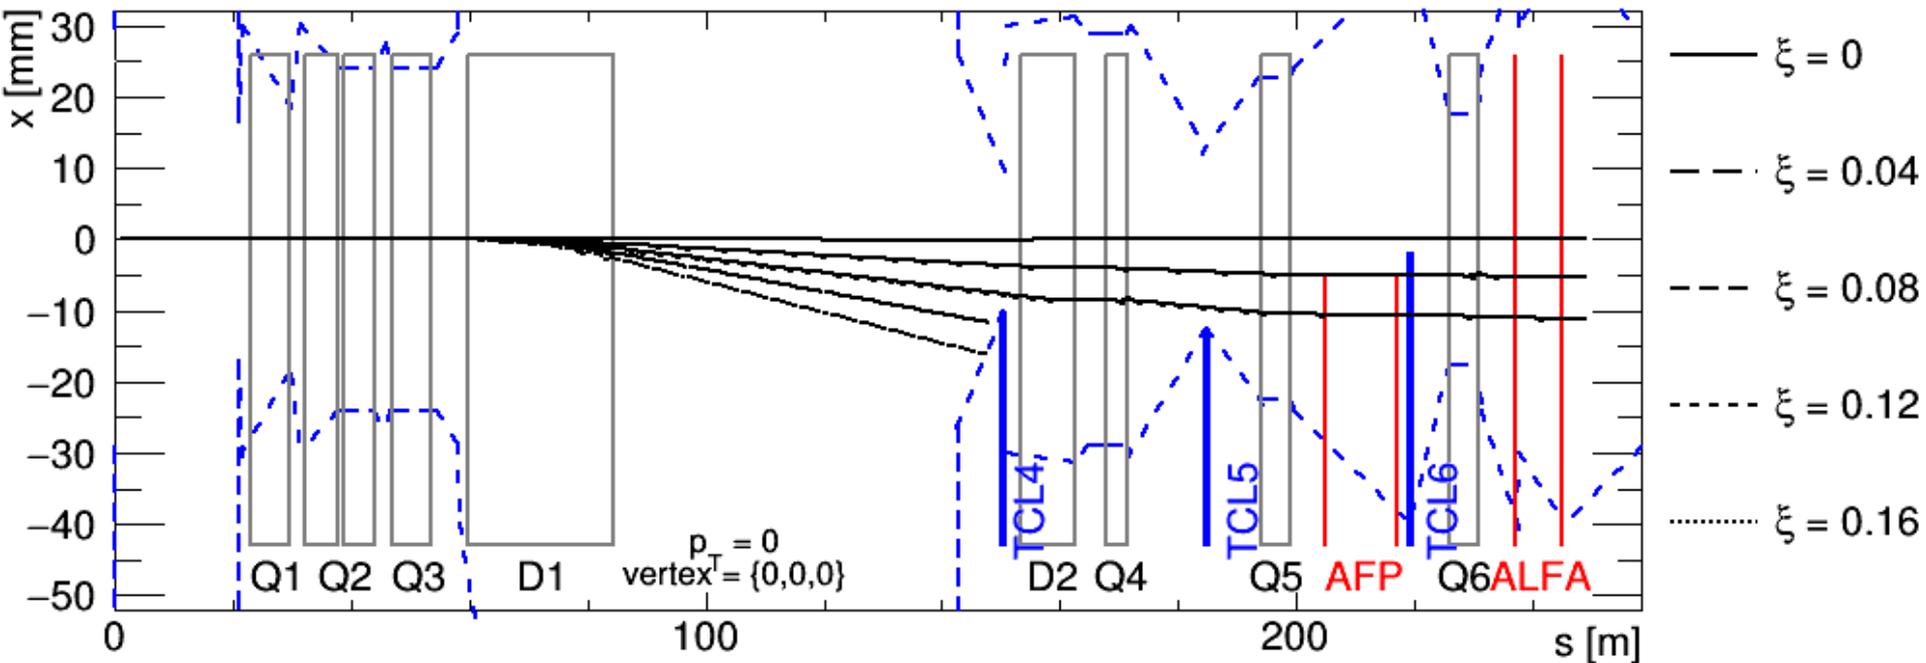

example.ProtonPositions ()

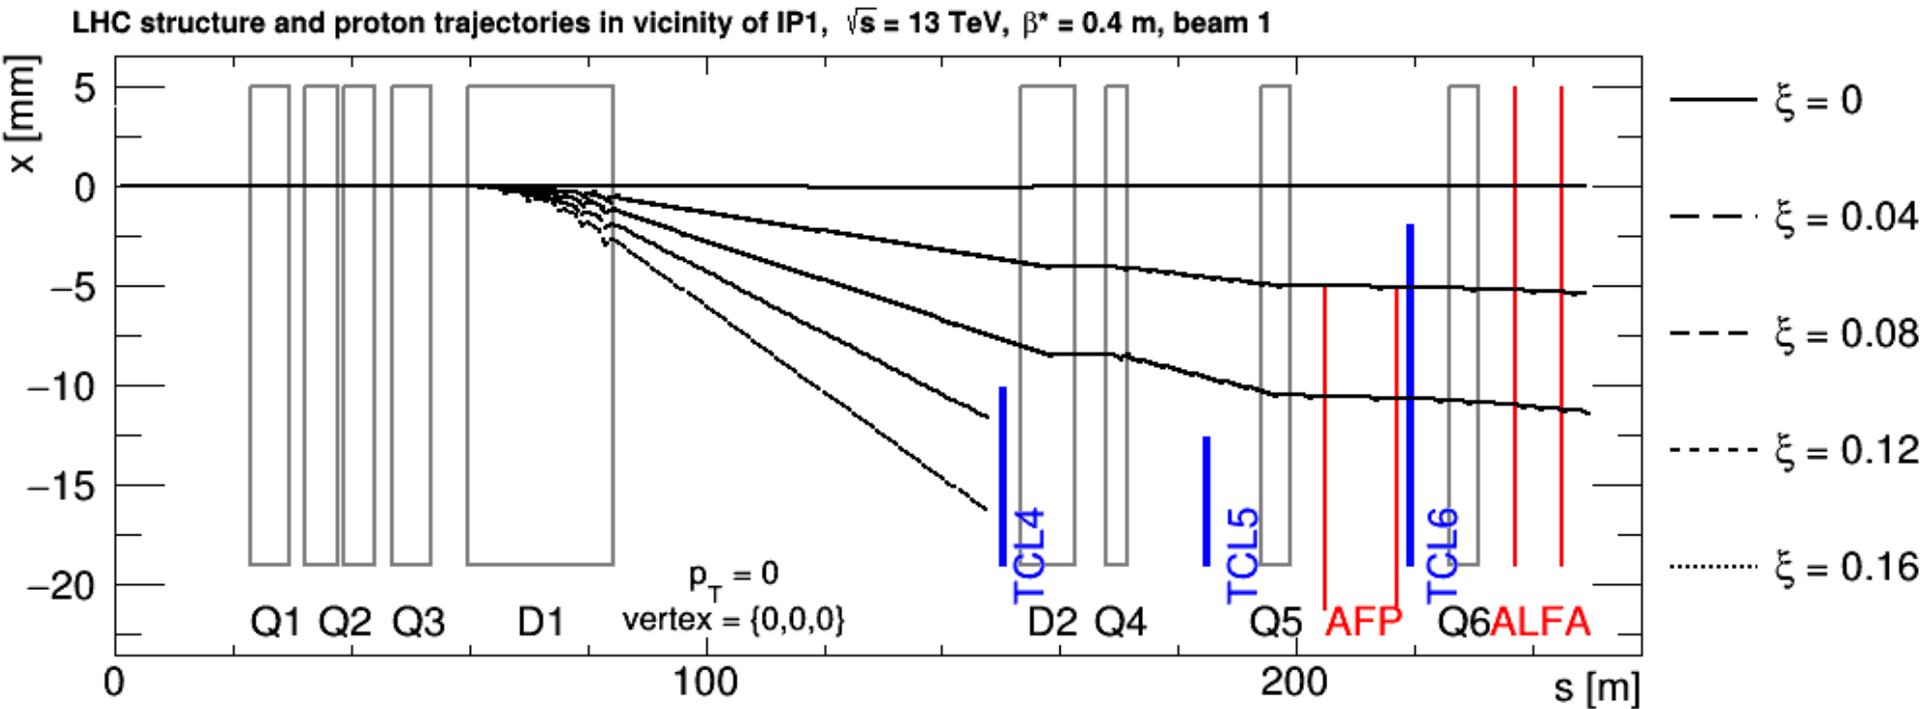

example.TrajectoryExamples (true)

LHC structure and proton trajectories in vicinity of IP1, $\sqrt{s} = 13$ TeV, $\beta^* = 0.4$ m, beam 1

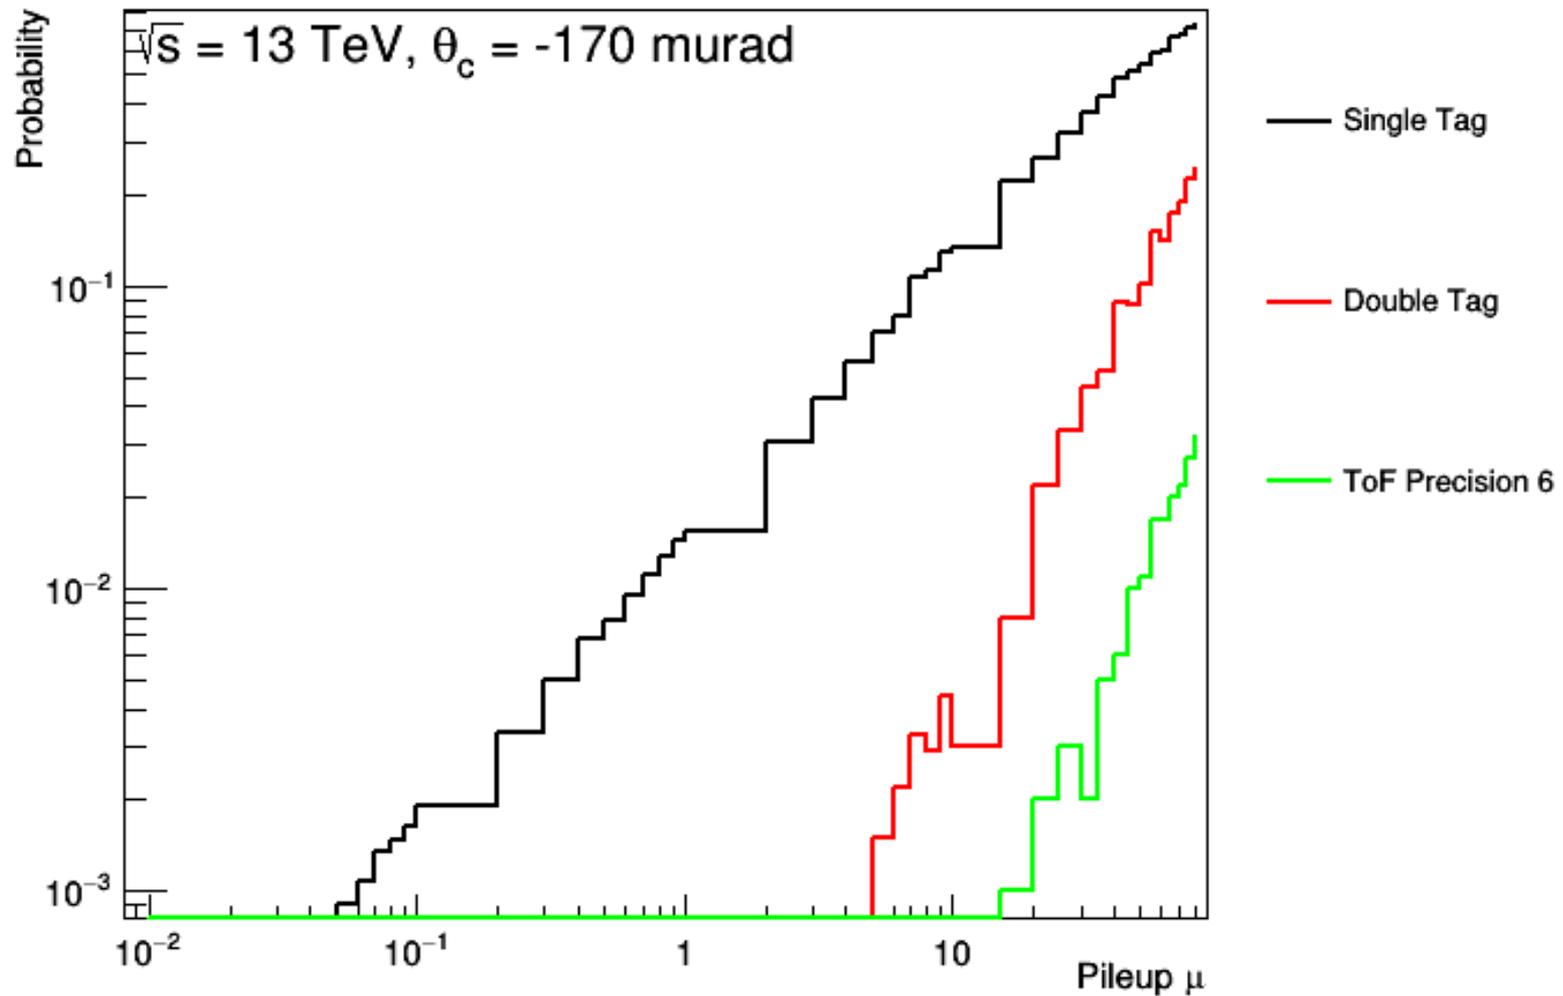

example.TrajectoryExamples (false)

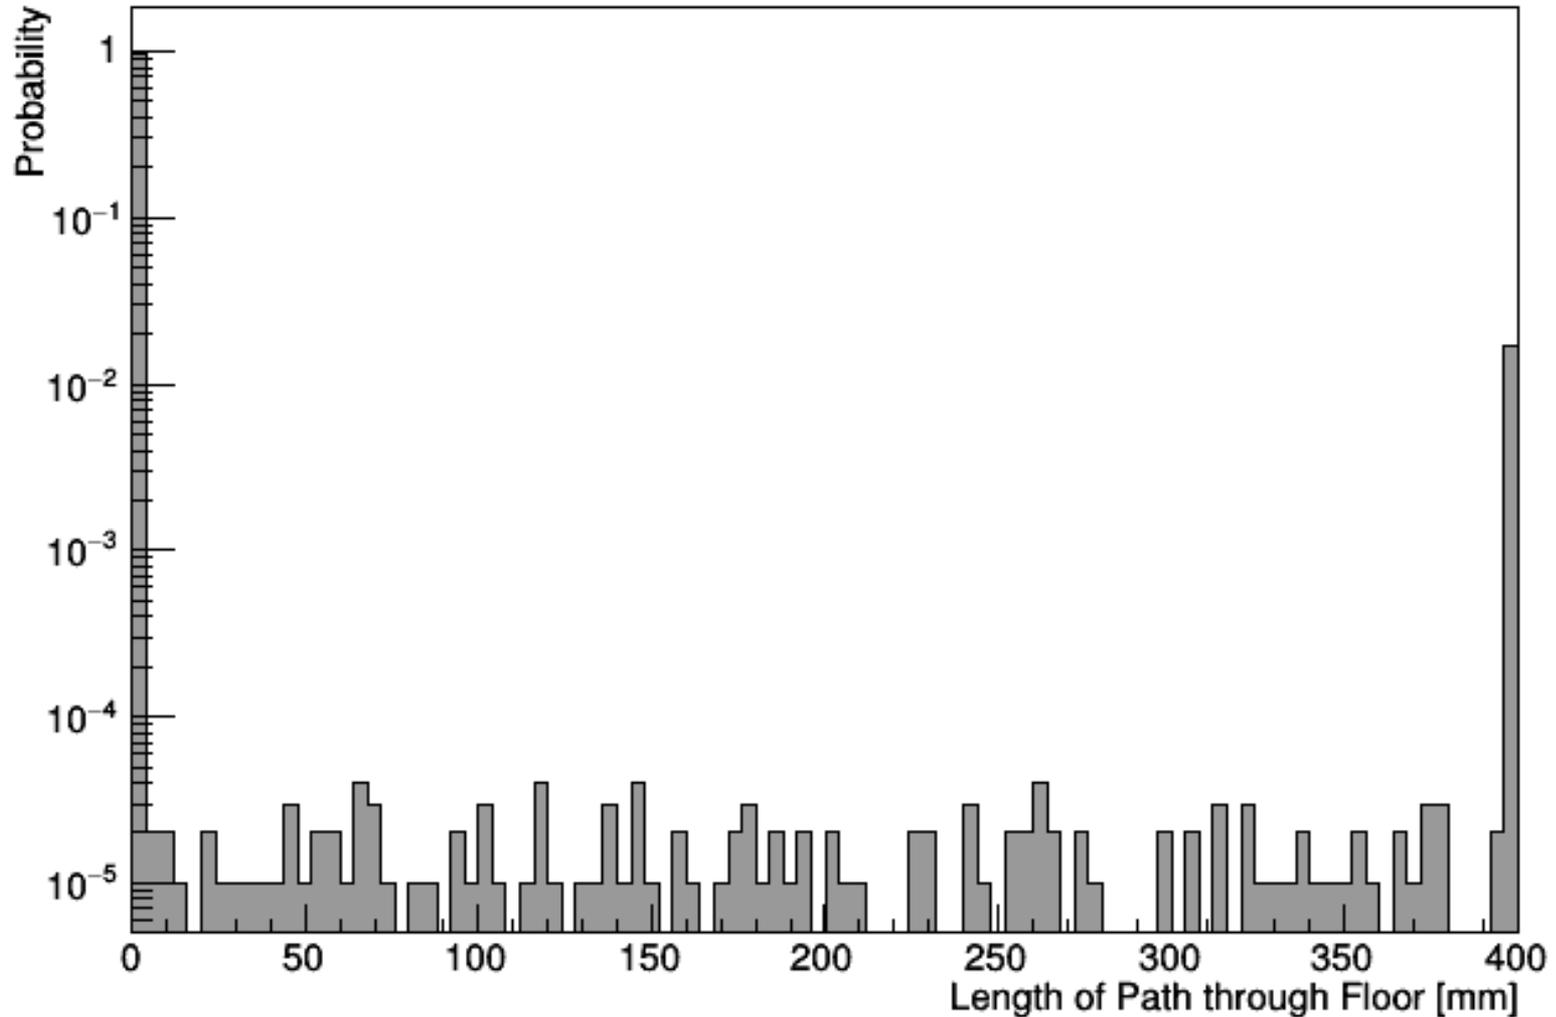

example.TagTimeProbabilities()

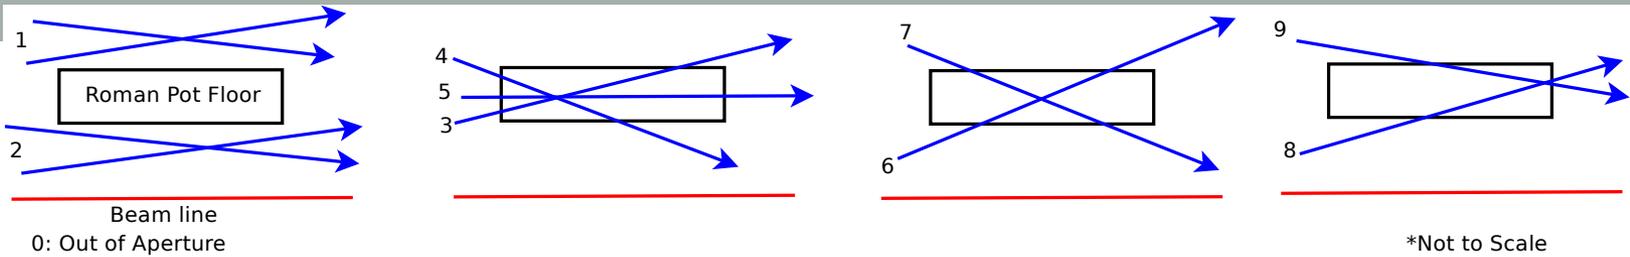

Tagging Probabilities

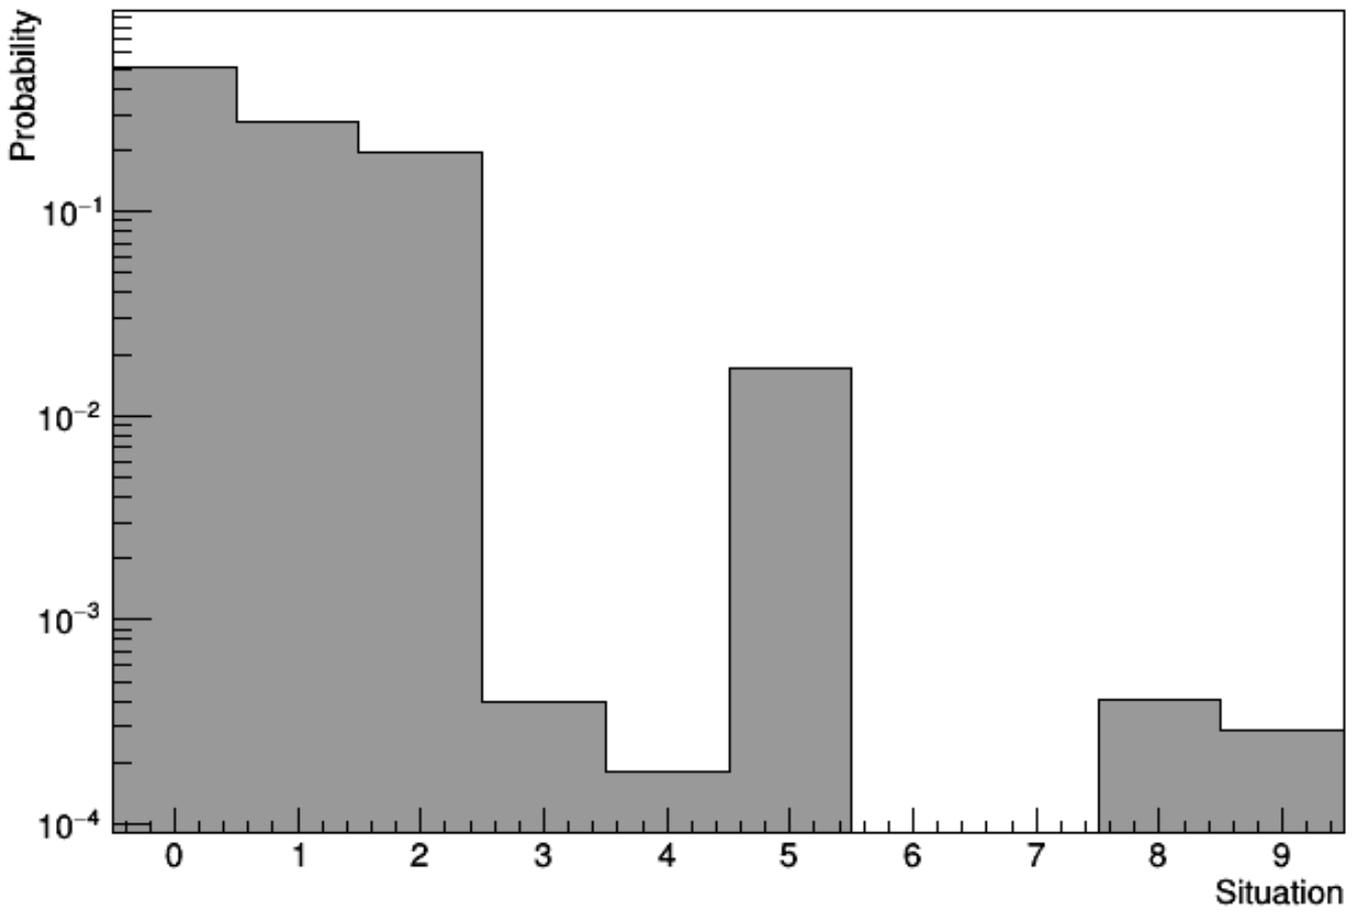

example.FloorLengthProbabilities()

Thin Floor Path Lengths A 205

Thin Floor Situations A 205

Parameterization

```
example.FindParameterisation(false);
```

- Calculates coefficients for polynomials of multiple different degrees
- Header generated in the same style as other programs
- User can either:
 - choose degrees of polynomials

```
example.PrintSpecificParameterisation(degrees);
```

```
example.ValidateSpecificParameterisation(degrees);
```

- run a method that tests each degree option against the simulation and chooses the best performing option

```
example.ValidateDegrees();
```

```
example.PrintPreciseParameterisation();
```

```
example.ValidatePreciseParameterisation();
```

Conclusion

- After library is compiled, can use interface class in another program.
- Structure allows for easy incorporation of new methods

Questions?

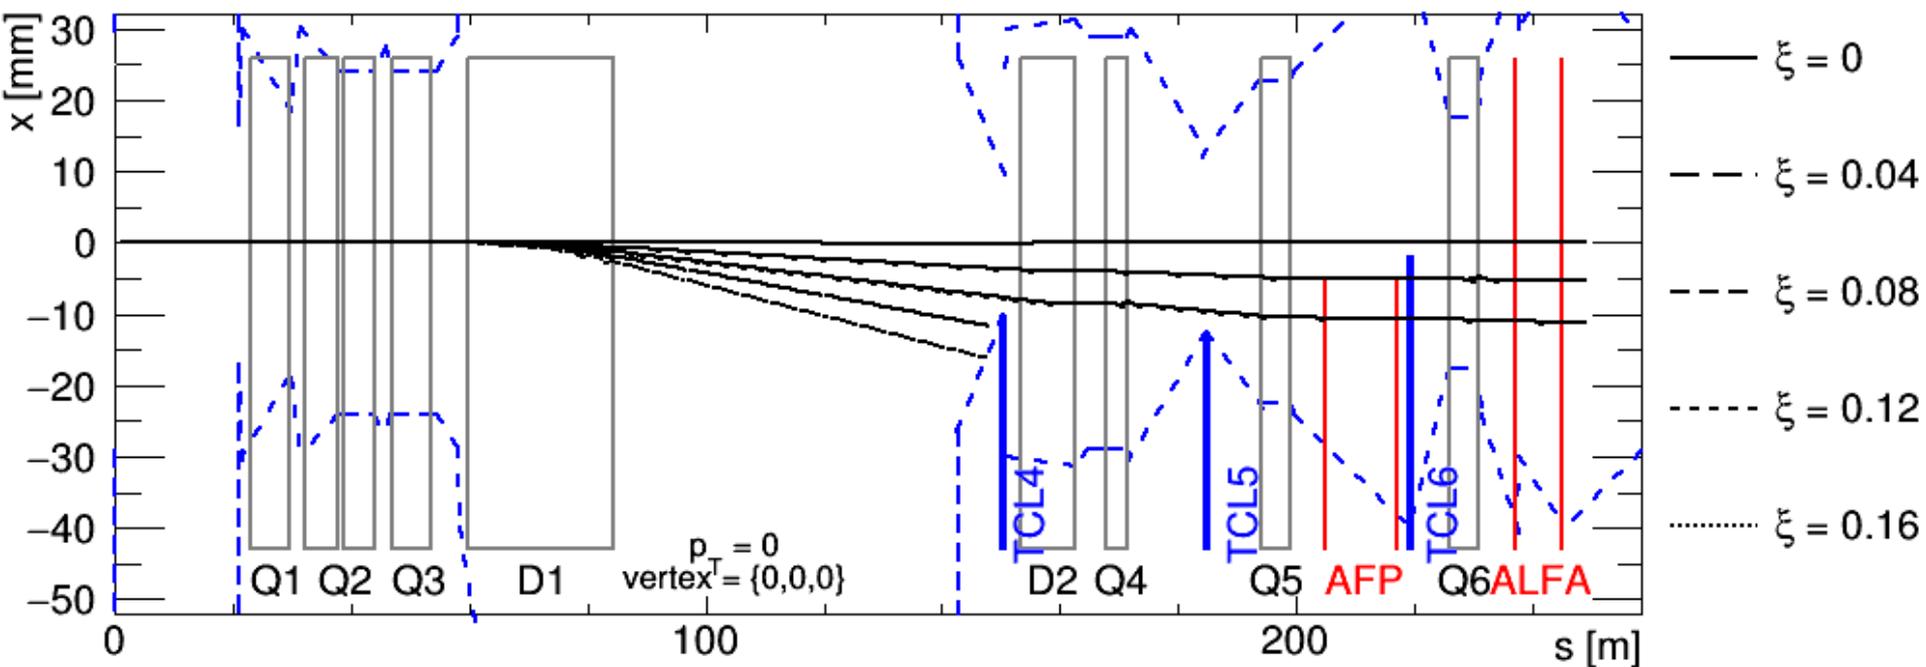

Code Structure

- Separates details into several different classes:
 - OpticsStudy: interface class
 - AFPStation: stores details on AFP detectors
 - OpticsMode: stores details on beam settings
 - Simulator: runs simulations using FPTracker
 - WriteTwiss: generates twiss files from MAD-X files
 - canvases/*: prints simulated data in specific method
 - parameterisation/*: determines and stores transport parameterization
 - simulationparameters/*: stores details of how simulations should be run

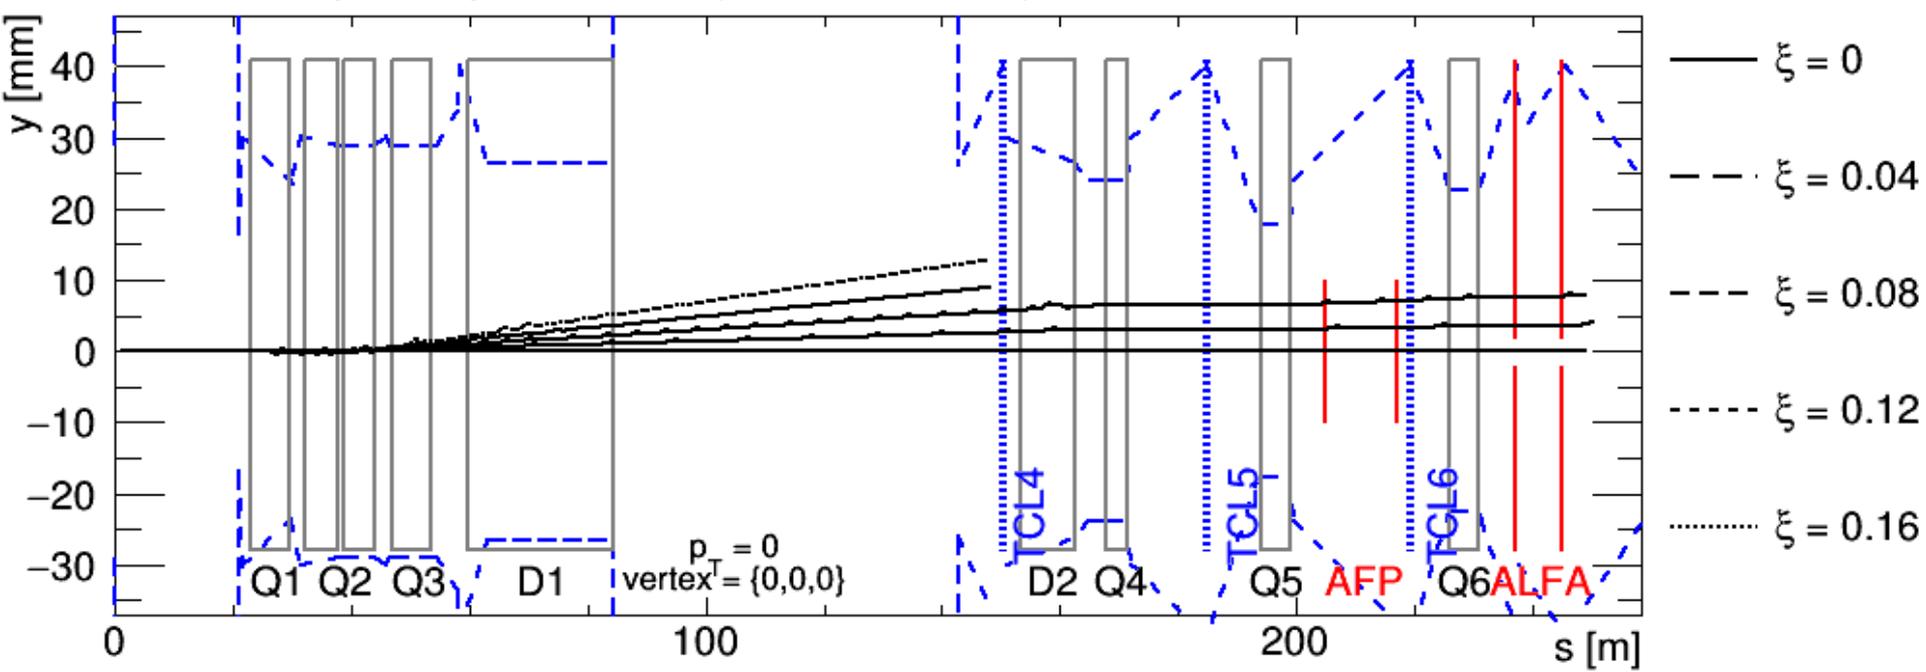

System Requirements

- All root libraries
 - Written using root v6.08/06
- Boost libraries:
 - boost_program_options, boost_filesystem, boost_system
- Compiler with C++ 11 as possible standard
- Compiled version of FPTracker
- MAD-X executable
