## Searching for Dark Matter

### Dark Matter Production

- ▶ We focus on dark matter production: can we see deviations from standard model invisible decays?
- ▶ Thus far, we've been able to put strong constraints on the masses of dark matter particles, but we have not yet observed dark matter production

# Future Circular Collider

## Motivation for Dark Matter Exploration

- ▶ Why haven't we observed dark matter production?
- ▶ One possibility: the cross sections for Higgs production are too low at our current energy scales
- ▶ The Future Circular Collider would reach order of magnitude higher energy scales, which would dramatically increase the Higgs production cross section

Summary

# Higgs Invisible Decays

## What is a Higgs Invisible Decay?

A decay from the Higgs boson to undetected final products

- ▶ Example of interest: dark matter
- ▶ Standard Model example: Higgs to neutrinos
- ▶ The current exclusion on branching ratio for Higgs to Dark Matter is 15%. At less than 1%, we can test some of the predominant dark matter theories

Summary

# What decays look invisible?

*In order to detect dark matter production, we must have high enough sensitivity to the standard model Higgs invisible decay to detect extremely small deviations from it.*

## Signal versus Background

- ▶ Though we are interested in dark matter, we cannot simulate dark matter production. Here, our signal is the Higgs decay to neutrinos.
- ▶ Key problem: many decays look like a Higgs to neutrinos decay. These decays are our background.

# What decays look invisible?

*In order to detect dark matter production, we must have high enough sensitivity to the standard model Higgs invisible decay to detect extremely small deviations from it.*

## Signal versus Background

- ▶ Though we are interested in dark matter, we cannot simulate dark matter production. Here, our signal is the Higgs decay to neutrinos.
- ▶ Key problem: many decays look like a Higgs to neutrinos decay. These decays are our background.

## Primary Background Events

- ▶ Z to neutrinos or low pt leptons
- ▶ W to a low pt lepton and a neutrino
- ▶  $T\bar{T}$  decays with a low pt lepton

# Distinguishing between Signal and Background

## Leading Jet Transverse Momentum

The background shown is the sum of the three backgrounds discussed in the previous slide (Z, W, and  $t\bar{t}$ ). Histograms are normalized to one.

# Distinguishing between Signal and Background

## Hadronic Recoil

- ▶ Hadronic recoil ( $u_T$ ) is the recoil against the hadron in transverse plane - equal to the transverse of the vector boson
- ▶  $u_T + MET + q_T = 0$ ,  $q_T$  is the pt of the vector boson

# Distinguishing between Signal and Background

## Dijet Mass

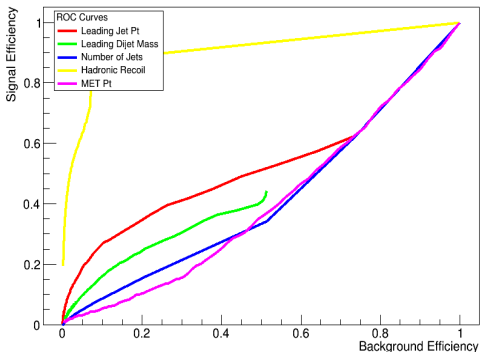

Dijet mass is the mass of the two leading jets

# Distinguishing between Signal and Background

## Receiver Operating Characteristic Curves

Which variables provide the best means of distinguishing signal from background?

► Gini index

Summary

# Eliminating Background Events

## First Round Veto

Vetoing events with one or two isolated, high pt leptons eliminates the majority of the Z and W background

## Matching

- ▶ Assume decays from Z or W to invisible products have similar properties to Z or W decays to visible products

# Eliminating Background Events

## First Round Veto

Vetoing events with one or two isolated, high pt leptons eliminates the majority of the Z and W background

## Matching

- ▶ Assume decays from Z or W to invisible products have similar properties to Z or W decays to visible products
- ▶ Match simulations of Z or W to visible leptons against the invisible outputs to determine what portion of invisible events were Z or W events

# Eliminating Background Events

## First Round Veto

Vetoing events with one or two isolated, high pt leptons eliminates the majority of the Z and W background

## Matching

- ▶ Assume decays from Z or W to invisible products have similar properties to Z or W decays to visible products
- ▶ Match simulations of Z or W to visible leptons against the invisible outputs to determine what portion of invisible events were Z or W events
- ▶ Uses a fitting algorithm developed several years. We developed a simple Heppy tree-builder to interface easily with the algorithm, which makes results more easily replicable.

# Summary

- ▶ The **Future Circular Collider** could be of great use for detecting dark matter.
- ▶ Detecting dark matter production will require **high sensitivity** to other invisible decay modes.
- ▶ We have developed an **easy-to-use method** of determining sensitivity, particularly for the case of Higgs invisible decays via the vector boson fusion production mode.
- ▶ Outlook
  - ▶ Apply our method to large enough vector boson fusion data sets to precisely determine the sensitivity of the FCC to Higgs invisible decays via VBF
  - ▶ Apply this method to other decay modes

# Acknowledgments

Many thanks to the National Science Foundation for providing the funding that made this research possible, and to the UM CERN REU team for making this a fantastic summer experience.

# Analysis Methodology

*How does the fitting framework work?*

## Basic Idea

- ▶ Inject a trial signal at every point along the histogram
- ▶ Float the fit until the ratio of likelihood of there being a signal to the likelihood of there being no signal is maximized (log likelihood)

# Analysis Methodology

*How does the fitting framework work?*

## Basic Idea

- ▶ Inject a trial signal at every point along the histogram
- ▶ Float the fit until the ratio of likelihood of there being a signal to the likelihood of there being no signal is maximized (log likelihood)

## What's special about this fit?

- ▶ We are examining a situation in which there are 6 control regions
- ▶ Each bin for a given control region is tied to the corresponding signal bin, so that all seven regions vary together
- ▶ Input uncertainties allow there to be small changes in how the 7 event types vary
